NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau requests and remittances should be directed to the Chief of the Bureau. The price of the Record is \$1 per volume, or 10 cents per number. The prices of other technical publications are given in the list above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XVIII.

FEBRUARY, 1907.

No. 6.

The need of a systematic study of the science of education was the main subject discussed in the address of Dr. C. M. Woodward as retiring president of the Association for the Advancement of Science, at its New York meeting. Doctor Woodward called attention to the fact that "the history of education is full of the records of whims and fancies, of experiments real and imaginary, conducted in order to prove the worthlessness of some theories and the worthiness of others. Every parent has a dimly defined theory of how his boy ought to be educated, and every teacher looking back over his own experience as a pupil formulates more or less clearly a 'system' for the proper education of his pupils. It goes without saying that such theories and so-called systems are generally shallow and inadequate;" but they nevertheless have their influence under our present conditions, and contribute to the confusion.

The speaker expressed his belief in a science of education, as a safe guide to the proper development and adjustment of our educational systems. "I do not claim to have formulated the science of education," he said, "and I know of no one living who has ventured to make such a claim; and yet I believe that a science of education is possible—and it is high time that we set about a systematic study of its essential features, with a view to a formal statement of its main principles."

He called attention to some of the fundamental principles which need to be worked out on a scientific basis—"Educational values are to be determined, taking into consideration age, sex, environment, taste, brain development, and probable sphere of usefulness." And he proposed the organization of a new section of the American Association, to be devoted to the advancement of the science of education, pointing out a wide range of questions for consideration by such a scientific body.

President Woodward's suggestions are especially timely in view of the changes both in subjects and in methods which are now taking place in school curricula, changes so marked that the term "new education" is not infrequently applied. The "new" in education has

come about largely through the introduction of so-called industrial subjects and the laboratory method of teaching. If it be true that there is confusion or lack of knowledge regarding the fundamental principles of education, which have engaged the earnest consideration of philosophers and sages for centuries, what of agreement can be expected concerning the essentials of subject-matter or method in teaching these newer subjects which have come into our schools within a few decades?

Take, for example, one of these industrial subjects, agriculture. It is only within comparatively recent times that the sciences upon which agriculture rests have been taught with any reference to their relation to the production of crops and animals, only within three or four decades that agriculture has been taught as a separate subject, and only within quite recent years that a science of agriculture comparable to the science of medicine has been recognized. Educators are not yet agreed upon the scope of this ancient art and modern science. They have not come to full accord as to the definition of agriculture. There are those who would confine it to plant production or agronomy, not including horticulture or forestry, while others would have it include in a general way not only all phases of plant production, but animal production, agrotechny, and such phases of economics, mechanics, and engineering as have a bearing upon the planning and management of farms, the construction and care of farm structures and machinery, the keeping of farm accounts and records, and the marketing of produce.

The relation of the instruction in the basal natural sciences to that in agriculture has also given rise to many pedagogical questions. Many educators insist that a thorough grounding in physics, chemistry, botany, and zoology is a prerequisite to a proper comprehension of the science and practice of agriculture, and should therefore precede any attempt to teach agriculture in schools. Others would so interweave instruction in the primary sciences and agriculture as to do away with separate courses in the former for students of agriculture.

In the very elementary agricultural instruction the children are taught facts concerning plants, animals, chemical elements, the laws of physics, etc., whenever a knowledge of these things seems to be necessary. In other words, the instruction proceeds through the concrete to the abstract, a plan which is quite generally advocated for elementary instruction, and which seems to meet with good success. Should this plan be carried on up through the high school and the agricultural college, thus doing away with all separate work in physics, chemistry, botany, and zoology? If not, at what point should the order of procedure be modified or reversed? It would

seem that fundamental research in agricultural education would shed light upon such problems as these. There are many others, among which may be mentioned the relative importance of the text-book, the lecture, the seminar, and the practicum in teaching agriculture, the rational basis for the development of the practicum, the educational value of agriculture and of the agricultural practicum, etc.

The problem which seems to be of the most vital present concern to the whole movement for promoting better agricultural conditions is that of training teachers for all grades of schools. The efforts which some of the colleges of agriculture are making along this line indicate that they appreciate the importance of such training and their duty in the matter, but as yet few of these institutions have undertaken serious work in the preparation of teachers of agriculture.

Eleven State universities with which colleges of agriculture are connected and one separate college of agriculture have departments of education, but only four of these have anything in their catalogues to indicate that agricultural subjects are in any way considered in the study of education. Six of the agricultural colleges (including two of those referred to above) offer regular normal courses, and one (Massachusetts) has a State appropriation to enable it to develop such courses. Two of these normal courses are innocent of agricultural subjects and another contains no pedagogy or other professional training in education. There are seven colleges of agriculture offering short normal courses of one to three years, thirteen that maintain summer schools for teachers, and five, not included in any of the above lists, that give one or two courses each in pedagogy, psychology, and history of education.

There are therefore thirty-two of the land-grant institutions for whites which offer courses intended for teachers; seven of these confine this work to short summer schools or to one or two units of pedagogy or psychology, leaving twenty-five that are making a serious effort to solve the teacher problem. Fourteen out of these twenty-five colleges mention agriculture in their courses for teachers. This is a modest showing, but it is encouraging in comparison with conditions a few years ago when scarcely a land-grant college in the country held out any inducement to teachers.

In some of these institutions the normal work is organized on a very broad and substantial basis. The University of Missouri, for example, has a teachers' college in charge of a professor of educational psychology. It offers undergraduate work leading to the B. S. degree and a life certificate for teachers, and graduate work leading to the A. M. and Ph. D. degrees. The studies include professional subjects in education such as the philosophy of education, pedagogy, school

supervision, etc., and also agriculture, horticulture, manual training, and other special or technical subjects taught by the professors and instructors in the college of agriculture.

In the University of Illinois there is a department of education with ten courses, and this year there has been added a special instructor to teach agriculture to prospective teachers. The University of Arkansas offers a four-year normal course in which agriculture and horticulture are taught. The Kansas College prepares teachers for three-year certificates, which are renewable for life. The Mississippi College has a department of industrial pedagogy and offers a four-year course in industrial pedagogy, which includes agricultural subjects. The State College of Washington offers fifteen courses in education, including one course in methods of teaching agriculture. The Massachusetts Agricultural College has a State appropriation of \$5,000 for the support of normal instruction and is planning to organize this work largely along agricultural lines.

The training of teachers of agriculture is just now a matter of great importance. Owing to the rapid development of the agricultural colleges, the establishment of many new agricultural high schools, and the introduction of agriculture into public secondary and elementary school curricula, the demand for capable teachers of agriculture is far greater than the supply. The normal schools in the different States have shown a commendable desire to meet this emergency, and some of them, notably in Missouri, Nebraska, Oklahoma, and Wisconsin, have succeeded in developing fairly strong secondary courses. But most of the normal schools have been compelled to content themselves with the more elementary work known as nature study and school gardening, such as would give preparation for the kind of work now generally done in city public schools.

A careful survey of the whole field reveals the fact that there is as yet no adequate provision for the preparation of teachers to take charge of agricultural courses in schools of agriculture, normal schools, or other secondary schools, nor is there any definite attention or encouragement given to the professional training of instructors for the agricultural work in agricultural colleges. The normal schools as at present organized can not do this higher work, nor can it be done by the great universities unless they maintain colleges of agriculture.

The duty of training teachers of agriculture for both colleges and secondary schools will, therefore, under present conditions, fall upon the agricultural colleges, and the needs of the time are so great as to make this duty almost imperative. Some of the larger agricultural colleges, especially those which are departments of universities, might well provide facilities and encouragement for fundamental research

in the science of education in its relation to agricultural subjects, and all should make provision for training teachers of agriculture.

By this it is not meant that the agricultural colleges should invade the field of the normal schools. They should merely do the work that the normal schools are not yet in position to do, nor can ever be in a position to do fully. The normal courses offered by the agricultural colleges should be no less thorough in their agricultural features than the courses now crowned with the bachelor's degree. On the other hand, it should not be thought sufficient for the agricultural colleges to offer one or two term electives in psychology or pedagogy or history of education, and say that the students who complete these subjects in connection with the regular four-year course are prepared to teach agriculture. The course for teachers should include the essential features of both an agricultural and a normal course, and these should be so brought together and combined as to make a well-balanced course, sound pedagogically, and affording training for the mind and training for the profession of teaching.

It may be said that such courses might now be arranged by election from the subjects offered in departments of education and in the colleges of agriculture of some of our universities. True, but not more than three universities in the country have thought this matter to be of sufficient importance to warrant mention of it in their catalogues.

Nearly every young person when planning his college course takes up old, well-established groups of studies or follows outlines suggested in the college catalogue. Hence the mere announcement in the catalogue of courses for the training of teachers of agriculture would tend to increase the number of students in these courses, by directing attention to them; and the colleges of agriculture where the necessary electives for a good normal course are now offered might well give some attention to arranging and announcing groups of studies adapted especially to the training of teachers of agriculture.

The colleges not now in a position to offer normal courses could easily prepare for this work by each employing at least one teacher of education and putting him in charge of the planning and arrangement of the normal course. He or his assistants would teach all professional subjects in education, and the other instructors in the college would attend to the other college subjects as they are now doing.

The Carnegie Institution of Washington has for several years been interested in the study of problems in human nutrition, which it has aided with grants. One of its first undertakings in that line was in connection with the investigation carried on by Prof. W. O.

Atwater, at Middletown, Conn., in cooperation with this Department, the work being continued under his successor, Dr. F. G. Benedict. This joint effort has been directed to increasing the efficiency and precision of the respiration calorimeter, previously developed with the aid of this Department, and especially to providing the oxygen annex, making it a closed-circuit apparatus.

So great has been the interest of the Institution in this work and its belief in the possibilities open to it, that it has decided to establish it as one of its permanent lines of research and to provide a special laboratory for it, as has already been done for a few other lines. The nutrition laboratory will probably be located in New York, in connection with one of the large hospitals, and will be devoted particularly to inquiries in relation to medicine, physiology, and hygiene. The fitting up of the apparatus and laboratory will be in charge of Dr. Benedict, who will direct the subsequent investigation.

There are many problems concerned with nutrition in disease and convalescence, and with the energy output and hence the food requirements of the body under various pathological conditions, as well as many questions of ventilation and other branches of hygiene, to the study of which the respiration calorimeter is especially adapted. Such questions have a wide interest and are of far-reaching importance, and as the Department's researches have developed there have been urgent requests that they be taken up. They are, however, distinctly separate from the investigations of the nutritive value of agricultural food products, to which the Department's efforts have been directed, and have seemed rather to belong to some other agency than one working primarily in the interests of agriculture and looking to annual appropriations for continuation.

It is especially gratifying, therefore, to all interested in the subject of nutrition in its broadest aspects, that the Carnegie Institution should have recognized its importance and decided to provide for it as one of its special departments of research. It is thus given greater permanency and greater freedom in scope than could be the case under legislative appropriation, and the possibilities are opened for extending the investigation into theoretical lines where it is much needed.

Especially is this departure gratifying to those who have been interested in the nutrition investigations under the Department, for it is a direct outgrowth of the latter's work which has led up to and made it possible. The development of the respiration calorimeter under the Department's cooperation, and the fundamental inquiries which have been conducted with it for several years past, have stimulated research in this field; and as the apparatus has remained the

only one of its kind in the country it has been looked to as the means of putting to exact test the deductions and conclusions from other investigation.

The wide interest awakened in nutrition studies, and the experimental methods which have been elaborated, are substantial products of the Department's work and influence in this line, and the step taken by one of the highest research institutions of the country is an indication of the way in which the Department's work may prepare the way for and stimulate research in the broader fields of science.

While plans for the continuation of these studies are not fully matured, it is expected that the respiration calorimeter at Middletown will be moved to Washington and installed in the new laboratories now building on the Department grounds.

PROBLEMS OF ANIMAL NUTRITION.^a

HENRY PRENTISS ARMSBY, LL. D.,
Director Pennsylvania Experiment Station.

Farm animals are kept substantially for two purposes—for the production of work and for the production of human food.

As regards work production, while it is true that horses and other work animals are being replaced to a greater or less extent by other prime motors, such as steam, gasoline and alcohol engines, and the electric motor, such replacement has not yet become possible on the small farm or for anything like all the purposes for which work animals are kept. The production of work is still, and is likely to continue to be, an important branch of animal husbandry.

The twelfth census gives the number of horses and mules over two years old in the United States as, in round numbers, eighteen and one-fourth million, worth one thousand million dollars. Estimating that these animals work on the average only four hours per day and generate three-fourths of a nominal horsepower each, we have the equivalent of the continuous production, night and day, of over two and one-fourth million horsepower, which is nearly one-third the total estimated horsepower of Niagara Falls and many times what is actually utilized.

Notwithstanding the importance of the animal as a prime motor, however, it is as a source of human food that he finds his principal place in American agriculture.

It is estimated by competent authority that over forty-five per cent of the food consumption of the better classes in the United States consists of animal and dairy products. Taking into account the relatively higher prices of these materials it seems safe to estimate that considerably more than half of the expenditure of the average family for food goes for this class of materials. Moreover, whatever, in the light of recent discussion, may be our attitude toward vegetarianism, or our judgment as to the necessary proteid supply, it is certainly a fact, however we may explain it, that those peoples are, as a whole, most efficient which consume a reasonable proportion of animal food.

^a Read before the section on experiment station work at the Baton Rouge convention of the Association of American Agricultural Colleges and Experiment Stations, November, 1906.

There were killed in the wholesale slaughtering and packing houses of the United States in 1900 five and one-half million cattle, nine million sheep, and thirty and one-half million swine, or a total of forty-five million animals, estimated to be worth \$683,000,000. The value of animals slaughtered on farms was estimated at \$190,000,000, making a total value of \$873,000,000. Adding to this the value of our dairy products, about \$433,000,000, and that of the poultry and egg production, about \$282,000,000, we have a total of about \$1,588,000,000 for the yearly value of the output of animal foods.

For both of the purposes just named, the animal utilizes the energy originally derived from solar radiation and stored up in vegetable products by the synthetic action of the chlorophyll. The point of economic importance in this connection is that these enormous aggregates represent to a considerable extent a utilization of the potential energy of inedible products which would otherwise be a waste so far as food value is concerned and largely so as a source of power. This is true on the one hand of the leaves, stems, husks, pods, etc., of our various farm crops—the so-called coarse fodders—and on the other, of those manufacturing by-products which accumulate in the preparation of grains and other raw materials for human consumption. By feeding these products to our domestic animals, we utilize for feeding man or performing his work a portion of their stored-up energy, which would otherwise be practically an entire waste. Of course surplus edible products are also utilized in stock feeding and in this country very largely so. This, however, can only be regarded as a temporary phase of our agriculture. While, on the fertile soil of the corn belt, it is often found more profitable to convert corn into beef or pork than to market it directly, as the density of population and the demand for breadstuffs increase, the stock feeder will be more and more constrained to the use of the cheaper by-product feeds in place of grain. From the economic point of view, then, it is highly important that that portion of our national wealth represented by these inedible products should be utilized to the best advantage, yielding a greater aggregate profit to the producer and a more liberal supply of animal food to the consumer.

Time prevents more than a mere reference to the important relations which subsist between animal husbandry and the preservation of soil fertility. While we no longer regard the farm animal as a mere manure machine, still the maintenance of the fertility of the farm is an important element in determining the profits of stock raising, and from this point of view, as well as from that of the more complete utilization of solar energy, those forms of agriculture are to be preferred, other things being equal, which maintain a due balance between the production of crops and of animals.

From all points of view, then, animal husbandry is a most important factor in our agriculture. Into the many exceedingly interesting and important questions regarding the breeding of farm animals I shall not enter at this time, both from lack of time and lack of qualification. The other half of the subject, that of the economic feeding of these animals, however, is certainly of at least equal importance with that of their breeding.

The experiment stations of the United States have not failed to recognize the importance of this branch of agriculture. The station literature of the last twenty years presents an imposing array of bulletins and articles treating of all phases of stock feeding. From a cursory survey we should be led to suppose that our knowledge of the subject was making rapid advances. A closer examination, however, will cause some modification of this first impression. In a paper read before the Graduate Summer School of Agriculture last July, Director Jordan presented a classified list of the subjects of the bulletins upon stock feeding issued by the stations for the years 1903, 1904, and 1905, which shows some rather startling facts. Out of a total of eighty-four bulletins, forty-three were reports upon comparative tests of either single feeds or individual rations. This form of feeding experiment has been almost as great a favorite as its analogue, the variety test, and the results have scarcely been more profitable in the one case than in the other. A reasonably diligent compiler could readily accumulate a great volume of data derived from such comparisons, but I think it very doubtful whether the results reached would be worth the labor. I venture to question whether stock feeders in general have derived very much real permanent profit from this class of experimental work.

Next most numerous on Jordan's list are the experiments, seven in number, upon the adaptability of certain feeds to special animals or purposes, a work most useful with new feeds, and yet a work demanding scarcely more appliances or attention than could be given it by a good practical feeder. Following these come, in equal numbers, experiments upon the substitution of home-grown for commercial feeds, and determinations of digestibility—both classes represented by five bulletins. The class first named—substitution experiments—are of undoubted economic value, but are necessarily of more or less local applicability. As regards digestion-experiments, I shall have occasion to speak later.

Not to prolong this enumeration, I think it is not doing injustice to the American stations, whether we judge by the record of these three years or by our general knowledge of their work, to say that while their investigations have brought to light or demonstrated to the farmer many useful facts, local or otherwise, they have served only to a very subordinate degree to reveal principles. The latter

we have seemed largely content to borrow from foreign investigators. To say this is not to deny the great value of much of the work done by our stations, nor to decry the publication of useful information. Nevertheless, the experiment stations stand before the country as the representatives of agricultural science, manned or presumed to be manned by scientific men. As scientific men we should know and should proclaim that permanent progress in agriculture is possible only through the establishment of principles. One principle well founded is worth a thousand facts, because it includes them all. I can not avoid suspecting that the principles which have been borrowed from foreign investigators and popularized by station literature and in other ways have done quite as much to help the practical feeder as our own experiments.

But how do matters stand with our borrowed science of feeding? Will it stand the strain we are putting on it?

The methods of comparing the values of feeds and rations which still largely prevail date back almost fifty years to the fundamental investigations of Henneberg and Stohmann at the Weende Experiment Station, in Saxony, begun in 1858 and published in 1860 and subsequent years. Our methods for the analysis of feeding stuffs, the technic of digestion experiments, and the interpretation of their results, are all, in the main, what were formulated by these investigators. They grouped the digestible organic matters of feeding stuffs into protein, fat, and carbohydrates, the latter including the digestible portion of the "crude fiber" and of the "nitrogen-free extract," and the values of feeds were estimated on the basis of the amounts of these nutrients which they could supply.

Henneberg and Stohmann, however, were fully aware of the fact that such investigation into the content of feeding stuffs constituted but one-half of the problem and that it was just as necessary to determine with equal exactness the real nutritive effect produced by their use. In 1870, in an introduction to a third report upon their work, Henneberg discussed very fully the methods by which this nutritive effect could be determined, with the aid of the respiration apparatus, on the basis of his familiar conception of the schematic body. Not only this, but he formulated a program of systematic investigations and made a beginning in its execution.

The determination of the digestibility of the nutrients in feeding stuffs, however, could be much more easily and cheaply accomplished than the actual determination of their nutritive value according to Henneberg's program. The assumption of the equal value of protein, carbohydrates, and fat from different sources having been once made, it was perhaps not surprising that the average experimenter should accept this assumption and follow the easier path. Almost innumerable digestion experiments have been made during the last forty-five

years, on the basis of which tables have been prepared which give us a very good general idea of the average composition and digestibility of feeding stuffs and of the extent of their variations. Somewhat later, so-called "feeding standards" were propounded in which it was attempted to formulate the amounts of the several nutrients best adapted to the various purposes of production. The general acceptance of this point of view was largely brought about by the writings of Wolff. The whole made a complete and simple system. So much is required for a certain purpose. This feed will furnish so much and the other so much. It is simply a question of arithmetic to work out a suitable combination, and a machine has even been devised for this purpose.

This system was introduced to the American public after it had assumed quite a definite form and it may be said in all fairness to still be, to a considerable extent, the basis of our theory. We question some of the standards, some of them we have modified, we hold them more flexibly than we once did, but protein, carbohydrates and fat are still the feeding trinity. Our theory of nutrition has become traditional, and has little pedagogic value for the student and little inspiration for the investigator. As a natural result it is more or less out of touch with practice, while our experiments, upon the theoretical side of the subject, have been "marking time."

With the publication of the results obtained by Zuntz and his associates upon the work of digestion, and of Kühn's and Kellner's respiration experiments at Moeckern, a new stage of progress was entered upon, to which I venture to hope that our own station in Pennsylvania has contributed a little. While the results of these investigations are best and most conveniently expressed in terms of energy, that is not the essential point. The vital thing is that in these experiments the amount of production due to each material experimented upon has been actually determined, with at least a fair degree of accuracy, by the laborious methods of the respiration apparatus or the respiration calorimeter. Enough results have already accumulated to show that many of the old values assigned to feeding stuffs vary widely from the truth. In particular these investigations have demonstrated the inaccuracy of the fundamental assumption upon which we have been basing our comparisons of feeding stuffs, viz, that digestible matter from different sources is equally valuable. For example, an experiment at the Pennsylvania Station showed the digestible organic matter of corn meal to be twenty-one per cent more efficient for maintaining a steer than the same amount of digestible matter from timothy hay, and fifty-six per cent more efficient for fattening. Kellner estimates the value of the digestible matter in numerous coarse feeds at only twenty to thirty per cent of

that of the digestible matter of grains, while Zuntz actually computes a negative result for the nutritive value of straw for the horse.

In the face of such differences as these, with what justification can we calmly continue to publish the old figures for digestible nutrients and to teach our students the conventional computation of rations?

Nor does it better matters much to add to our tables figures for the so-called "fuel values" of feeding stuffs.

In the first place, the figures commonly given are incorrect. They are based in most cases on Rubner's or Atwater's factors for human dietaries, and while these factors have been shown to be substantially accurate for the purpose for which they were intended, they have also been shown to be grossly inaccurate when applied to the digestible nutrients of stock feeds, the results being too high, in some cases by as much as twenty-five per cent.

In the second place, even if these energy values were correct, they do not help us much. We can not rejuvenate the old tables in this way. The writer is fully convinced of the advantages for many purposes of regarding nutrition problems from the standpoint of energetics, but it needs to be emphasized that the advantage of the calorie over the pound is simply as a measure. It is a better measuring stick than the pound, with a wider range of uses, but it is still a measuring stick—an implement—and the value of the results depends on what and how we measure. The prime failure of Henneberg's successors was not in the units which they used, but that they failed to measure the real nutritive effect of their feeds and rations, and we but repeat their failure when we seek to make progress by substituting these energy values for the equivalent amounts of matter. It is doubtless very desirable to know the amounts of digestible matter in feeding stuffs and the corresponding quantities of energy more accurately than we do at present, but neither the one nor the other by itself gives us any definite information as to the use made by the organism of the matter or energy supplied in the feed. It is only as we determine by the use of the respiration apparatus or calorimeter (or possibly by the comparative slaughter test) the actual changes brought about by the feed in the store of matter or of potential energy contained in the body that we can reach a scientifically accurate determination of the nutritive value of that feed. Unless we do this, no matter how accurately we analyze the feeding stuffs supplied or determine their energy, the second member of the equation is lacking. We stand in urgent need of actual determinations by modern methods of the nutritive values of feeding stuffs for different purposes, the results of which we may substitute for the assumptions on which we are now basing our teachings.

I may instance in particular the importance of determinations of

the maintenance values of feeding stuffs, in which a beginning has been made by the Pennsylvania Station. The results thus far reached hardly do more than show the need for further investigation. The experiments should be repeated with additional animals and extended to cover at least typical members of the different classes of feeding stuffs. Several years' work might be expended profitably on this single branch of the subject. Were this done we might fairly hope, I think, to secure approximate factors which could be applied to those feeds whose maintenance values had not been directly determined. If successful we should secure an indispensable factor for the discussion of the results of productive feeding, since it is evident that we must know how much of our ration has served simply for maintenance before we can rationally consider its productive value.

As regards the production values of feeding stuffs, we are better off, in that we have the results of Kellner's elaborate and exceedingly valuable determinations. For the feeding of mature fattening cattle it seems probable that the "production values" thus worked out may at least be regarded as a very close approximation to the truth. Here again, however, it is to be feared that we are in danger of repeating the mistakes of Henneberg's successors. Kellner has published a very complete table of actual or computed production values. It would not be surprising if there should develop a tendency to accept these values as measuring the worth of feeding stuffs for all productive purposes. In other words, there is danger that we may rest in an assumption instead of actually determining the facts for ourselves. The results of our Pennsylvania experiments certainly indicate that the values for maintenance are higher than those for production. It would not be at all surprising if the production values for different purposes or for different classes of animals should prove to be materially different. At any rate we have no warrant in advance of investigation for assuming that they are identical. We need similar determinations by equally rigorous methods of the productive values for other purposes, which are by no means necessarily the same as for fattening. Here, again, we have a vast field open to the qualified and patient investigator, equipped with the necessary appliances.

It may be objected that investigations such as those just outlined are to a degree empirical. They treat a single feeding stuff as an entity, while as a matter of fact it is not. We can determine the net available energy of a given sample of timothy hay, but we can hardly be said to determine the available energy of timothy hay. The justification for making such determinations lies in the fact that they promise to yield approximately correct and useful results within a reasonable time. Too great emphasis can hardly be laid upon the importance of studies of the physiological values of individual chemical ingredients. Such results, when once established, are definite, because they refer to

a definite substance, but on the other hand it will be a long time before a sufficient number of results of this sort are accumulated to furnish a sufficient basis for a science of feeding.

Finally, at least mention should be made of the importance of research upon the influence of condiments; that is, of the various flavoring and aromatic substances contained in feeding stuffs—what the Germans call *Reizstoffe*, which might be translated “stimulants,” were it not for the unfortunate connotation of that word. We know that these substances exert an important influence upon the nutritive processes in the animal, but beyond this our knowledge is vague and qualitative.

The lines of investigation thus far suggested have to do with the relative values of feeding stuffs. The general applicability of any such results, however, has been questioned because of varying individuality in animals. That such variations, and striking ones, do exist is undeniable. It is not difficult, however, to suggest plausible explanations for them other than differences in the physiological utilization of the nutrients digested. For example, if of two animals one has a maintenance requirement five per cent greater than the other, due perhaps to greater restlessness of disposition, the quieter animal will do better than the more restless one upon a given ration, not because it uses its food physiologically to better advantage, but simply because it has more left for productive purposes after meeting the needs of maintenance. So too, if of two animals otherwise identical, one is able to consume continuously ten per cent more food than the other, it is obvious that a correspondingly larger proportion of its food is available for productive purposes, since the same amount must be subtracted for maintenance in both cases. I instance these simply as possible explanations without intending to assert that they or similar ones are sufficient to account for all the observed difference. The point is that the question is one needing investigation.

In the first place, the maintenance requirements of different species of animals, and their variation both as to proteids and total food, should be more fully investigated. At the present time, only the data for cattle can be regarded as fairly satisfactory. Such results are indispensable for the rational study of the results of practical feeding experiments. The influence of such factors as breed, individuality, age, weight, and condition on the maintenance requirement should be examined, as well as such external factors as the influence of the surrounding temperature and of the greater or less incidental activity of the animal. By careful methods much valuable information regarding the actual maintenance requirement of animals may be gathered by a combination of live weight and digestion experiments. When, however, we come to ask whether the maintenance value of a given feeding stuff, or in other words, the net availability of its energy,

varies with the animal to which it is fed, the aid of the respiration apparatus or calorimeter is indispensable.

We need also experiments upon the food requirements for production of various sorts. I can pause only to indicate a few of the problems under this head.

First, we have the proteid requirement. The question of the minimum proteid requirement has been brought to the fore by the investigations of Chittenden and others upon human nutrition. Since protein is usually the most expensive ingredient of rations, we need determinations of the actual amounts required, for instance, for growth at different ages. It would be interesting to determine whether there are individual differences in the rate of growth of proteid tissue, and whether this rate of growth can be stimulated by an excess of proteids in the ration. Similarly, for milk production, we attribute a stimulating effect to the proteid supply in excess of that appearing in the milk and excreta, but have we any real demonstration of such a fact? In the case of our working animals, we know that the work is done largely at the immediate expense of the nonnitrogenous nutrients, but have the proteids no function in the matter, and is the universal practice of athletes, for example, to consume large amounts of proteid food a mere habit or tradition and of no significance to us in the feeding of work animals? Questions such as those last indicated can, of course, be studied purely from the standpoint of the nitrogen balance of the body, but the history of investigations upon work production makes it evident that a comprehensive study of the subject requires also a study of the total metabolism, and this again necessitates the use of the respiration apparatus or calorimeter.

Variations in the total food demand due to individuality, age, weight, condition, and the like appeal for solution, and that solution can be reached only by accurate scientific methods. Similarly, in milk production the question of the factors influencing the distribution of the food between milk and tissue production needs thorough investigation. Again, the influence of such factors as temperature, water consumption, exposure to storms, humidity of the air, and the like needs be only mentioned to show the need for further systematic investigation.

Finally, a mere mention of the influence of feed upon the quality of the product must serve to simply hint at a most fertile field of investigation.

But because I have thus far dwelt almost exclusively upon the scientific and almost recondite aspects of the study of feeding, I would not be thought to hold that this is the only kind of work that ought to be undertaken or that no one should venture upon the field with any less formidable equipment than a digestion stall and an

Atwater bomb—not to say the heavy artillery of respiration apparatus and calorimeter. The sling may still prove a formidable weapon, if wielded by the hand of a David, and the smooth pebble from the brook may still do its wonted execution. It is largely a question of aim.

The discovery and establishment of natural principles and laws require the rigorous methods of physical and chemical research. By this path alone can we hope to attain a clear and definite quantitative conception of the processes of nutrition. But this alone is no more sufficient than the practical feeding experiment. We are dealing with an applied science, and our task is only half completed when we have established the fundamental principles of nutrition. We are under an equal obligation to show how these principles apply to the practical problems of feeding, and for this purpose nothing can take the place of actual experiments under the conditions of practice. If our practical experiments in the past have not been fruitful of general results it is not because they have been practical, but rather because they have not been so in the best sense. In too many cases they have lacked aim. They have not been informed by that comprehensive view of the whole subject which constitutes the essence of science, and so, addressing themselves to petty temporary or local questions, have, while admirable in their technical detail, failed to materially advance our knowledge. The more thorough and exhaustive our scientific studies of nutrition become, the greater will be our need for correlated practical experiments, scientifically planned to answer definite questions regarding the application in practice of the principles worked out in the laboratory or the respiration apparatus.

While this paper was in course of preparation, I received, from one of the leading investigators in animal husbandry in this country, a letter containing a number of inquiries regarding certain points in animal nutrition. If designed to reveal my limited knowledge of the subject, the letter was an unqualified success. To nearly all the inquiries I was compelled to return either conjectures or a simple "I don't know." I was, however, greatly interested in the letter from two points of view. In the first place, it illustrated the possibility of which I have just been speaking, namely, securing results of general value from practical experiments. The investigations which this gentleman has been carrying on have related primarily to questions of practice, yet he has been able to plan his experiments and study his results so as to give them an important bearing upon certain questions regarding the principles of nutrition. In the second place, the letter illustrates the inadequacy of the practical experiment alone and the necessity for scientific investigation along parallel lines. His experiments and experience raised questions which could not possibly

be answered by such experiments, and yet they were questions which he, as a practical man, found of importance. His results would be of very great value in confirming or checking the conclusions from scientific investigations, yet, taken by themselves, they were indecisive and capable of more than one interpretation.

Systematic studies of the practice of successful feeders should aid largely in this phase of the work. We might, I believe, find an important field for this sort of investigation in the feeding experiments recorded in the bulletins and reports of the stations. These experiments have been conducted and reported with far greater care than are or can be the operations of the practical feeder. Doubtless a wise criticism would have to be exercised in their selection and discussion, but they constitute an almost unworked mine of valuable material. To cite a single personal illustration, the writer has somewhat recently undertaken a comparison of a few of the more readily available station experiments upon the fattening of cattle with reference to the proteid requirements of such animals. The results need not be quoted here; it is sufficient to say that they showed a strikingly good general agreement, and to that extent seem calculated to furnish a good guide for practice. Had it been possible to make a systematic search of station literature, doubtless the available data might have been largely increased, but such an undertaking is usually beyond the means of the individual investigator.

This last suggestion leads naturally to the consideration of a related line of activity, namely, the compilation and critical discussion of the literature of animal nutrition in general, so far as it is of value to the stock feeder. As a matter of course, such study and compilation would accompany the scientific investigations already suggested, but in addition there is a vast amount of recorded data, both American and foreign, available, out of which much valuable information might be dug which would serve to check and correct our conclusions from small-scale experiments. The work needs to be done, but its volume almost discourages one from making an individual beginning. In brief, we need, parallel with scientific investigations into principles, a comprehensive sifting, working over, and systematizing of the facts already on record.

I have thus endeavored, after pointing out the economic importance of the subject, to indicate the unsatisfactory nature of our present knowledge regarding the principles of stock feeding, and the need of broadly planned investigations in this field, and have ventured the attempt to outline in general terms some of the investigations needed. There still remains to be considered the administrative question of how systematic investigations of the sort needed can be most effectively promoted, and this again is part of the broader question of how far fundamental investigations into principles can legitimately and reasonably be expected from our institutions for agricultural research.

No simple and categorical answer is possible to this question. Diverse conditions and abilities must always be reckoned with. At the same time, certain things may be suggested, with special reference to this particular subject but of more or less general application. It may be remarked, in the first place, that in any such undertaking, whether along the lines suggested by this paper or relating to other subjects, there is need for a degree of coordination of effort. I am well aware that I am here treading on delicate ground, but without stirring up smouldering fires, may we not freely and fully recognize the fact that, while duplication of work, of which we have heard so much, far from being discouraged should be encouraged, a certain common understanding of the broader features of the problem and of the most promising means of approach to it—to a degree, even a program—is essential to satisfactory progress?

The fact is we have been carrying on a guerrilla warfare around the edges of the subject. Indeed, in pessimistic moments, I have sometimes feared that our stations and colleges have been quite as successful in capturing prizes at fat-stock shows as in developing the science of feeding or imparting pedagogic value to the subject. What we need is to plan a campaign against the unknown. Let me hasten to add, however, that this military metaphor, like all others, should not be made to "go on all fours." It does not necessarily imply military discipline or a commander-in-chief. What is important at the present time is that there should be some means of inspiring and promoting serious and systematic work in this field, guided by a broad view of the subject.

The writer hopes to be able to contribute something to the progress of science along this line, and recognizes gratefully that circumstances have put greater opportunities at his disposal in some particulars than most of our investigators have hitherto enjoyed, but a few workers in a single institution seem like a forlorn hope when we contemplate the vast territory to be occupied. We need a dozen calorimeters instead of one. Above all, we need some means of guiding and to a degree coordinating the work of the younger men in our stations without depriving them of their initiative or of their individual credit for their investigations. Moreover, we need provision in some way for what may be called the drudgery of the work, for the computation of results, for the compilation of literature and other work of the sort.

How this shall be accomplished, I am far from undertaking to say. The stations as a rule, I think, appreciate the importance of the matter, but, as I took occasion to say recently in another connection, the pressure upon those in responsible charge of our experiment stations for results of immediate utility is such that it requires exceptional conviction and courage to set aside liberal sums for pure

scientific research. The U. S. Department of Agriculture has the advantage of a broader constituency, and to a certain degree, of larger freedom in its choice of subjects for investigation, yet, it too, perhaps even more than the stations, feels the pressure for popular approval. The problem is really one of educating our constituency.

It seems yet an open question how far it will prove possible for the experiment stations, with their pressing practical problems, to enter vigorously and aggressively into pure scientific research in the immediate future, either in this or other fields. The passage of the Adams Act has made this a live question, and it is most earnestly to be hoped that this fund will be used scrupulously in accordance with the spirit as well as the letter of the law, and that the reflex influence of this will extend to expenditures under the Hatch Act as well. State problems should be studied at the expense of the State and the national funds used for those broader investigations which are to benefit the whole country. It is to these funds and to those of the National Department of Agriculture that we must look for the promotion of comprehensive schemes of fundamental investigation whose results will become the common property of investigators everywhere.

I am inclined to see possibilities for larger service in this direction on the part of the U. S. Department of Agriculture than, I think, are some of my colleagues. Suppose, for example, that the Department were able to undertake a comprehensive scheme of investigation upon stock feeding corresponding to that which it is conducting so successfully in human nutrition. While the Department could hardly hope to find an Atwater to organize and direct the undertaking, yet with even a moderate degree of tact it surely ought to be able to attract the interest and confidence of the stations to its work, so that it would be to their manifest advantage to correlate their investigations with its own, whether officially or unofficially. For one, I can hardly doubt that such a course, patiently adhered to, without effort for notoriety and depending on moral authority alone, would be a powerful influence in favor of unity of work and of the study of fundamental questions by scientific methods, as well as in training men in the methods of investigation. That the same methods might be applied to quite other lines of investigation is, of course, too obvious to require mention. Indeed, it is a phase of the vexed question of cooperation which seems to me well worth careful thought—the essence of the method, of course, lying in the personality of its executor.

After all is said, however, it may be questioned whether, in the present temper of the public mind, the more abstract forms of scientific research can be adequately maintained by institutions dependent en-

tirely upon taxation for their support. The average taxpayer has come to have a considerable degree of confidence in scientific investigation, but he does not like long-term investments. He wants to see results, or at least the definite prospect of results, within a comparatively short time. This doubtless has its wholesome side as a discourager of dawdling and dilettanteism, but on the other hand the public has yet to learn that "the search for knowledge, with exclusive reference to its practical application, is generally unrewarded."

I believe that the question of the permanent endowment of research in agricultural science, either in special institutions or in our great universities, is a subject well deserving the consideration of all interested in agricultural progress, and that an investment of this sort would yield richer returns of honor and satisfaction to the donor than many a memorial pile or stately library.

Nor are the amounts required large as compared with the magnitude of the interests involved. Thus, to take the single subject of this paper, a sum sufficient not only to equip, but to permanently endow an institution for research in animal nutrition far superior to any now in existence anywhere would equal less than one-twentieth of 1 per cent of the value of our live stock and dairy products in a single year. Two cents per \$100 upon the average value of the live stock handled yearly at the Union Stock Yards for the last five years would amply equip such an institution, and a liberal revenue for its maintenance would amount to 1 cent per head upon the cattle alone slaughtered yearly in Chicago. But the endowment of research in agriculture is too large a subject to be entered upon at the close of a paper of this length, and I forbear to tax your patience further.

I am conscious of having spoken with a certain degree of personal bias in urging as I have done the importance of, and necessity for, fundamental investigations in a branch of science in which I am deeply interested. For this I make no apology. If anything which I have said proves of service in promoting scientific investigation in any branch of agriculture, I shall feel amply justified.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

Quantitative volatilization of phosphoric acid, P. JANNASCH and E. HEIMANN (*Ber. Deut. Chem. Gesell.*, 39 (1906), pp. 2625-2628; *abs. in Chem. Centbl.*, 1906, II, No. 17, pp. 1357, 1358; *Jour. Soc. Chem. Indus.*, 25 (1906), No. 20, p. 1007).—In the method proposed 0.5 gm. of phosphate is carefully heated in a flask in an open air bath with about 6 to 8 cc. of a mixture of 30 cc. of saturated cane sugar sirup and 10 cc. of sulphuric acid (1:1), a stream of air being passed through the flask until carbonization is complete and the mass is dry. The flask is then connected with a receiver and heated to the highest temperature it will bear, a stream of chlorine being passed through until no more condensable products come over. Oxygen is then substituted for chlorine until all carbon is burnt. After cooling, 3 to 4 cc. of the acid sugar solution is added and carefully spread over the inner surface of the flask and the above process repeated.

By this method the authors volatilized phosphoric acid completely from ammonium and magnesium phosphates. The extension of the process to other phosphates is being investigated.

The Woy method for the determination of phosphoric acid, G. B. VAN KAMPEN (*Chem. Weekbl.*, 3 (1906), pp. 576-579; *abs. in Chem. Centbl.*, 1906, II, No. 17, p. 1357).—The author maintains that this method is as accurate and satisfactory as the ordinary molybdenic method. Like Woy, he finds the ignited residue to have a composition of $24\text{MoO}_3\text{P}_2\text{O}_5$. He considers Hundshagen's method unsuited to volumetric analysis on account of the slowness of filtration of the precipitate.

Process for rendering mixed combinations of phosphoric acid and silicic acid easily soluble, P. A. NEWTON (*English Patent No. 9183, Apr. 18, 1906; abs. in Jour. Soc. Chem. Indus.*, 25 (1906), No. 20, p. 997).—In this process the raw phosphates are fused with artificial alkali silicates and lime in a regenerative Siemens' furnace and the molten product is run directly into cold water. It is stated that in the product thus obtained nearly all of the phosphoric acid is citrate-soluble.

Availability of phosphoric acid of the soil, G. S. FRAPS (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 7, pp. 832-834; *abs. in Jour. Chem. Soc. [London]*, 90 (1906), No. 528, II, p. 702).—A brief statement of the principal contents of this article will be found in *E. S. R.*, 17, p. 611.

The determination of nitric acid in soils, E. GUTZEIT (*Landw. Vers. Stat.*, 65 (1906), No. 3-4, pp. 217-219).—The inaccuracy of the determination of nitrates in presence of humus, as is done for example in Buhlert and Fickender's method (*E. S. R.*, 17, p. 832), is pointed out.

The determination of humus acids in soils by the Tacke method, C. K. VAN DAALEN (*Chem. Weekbl.*, 3 (1906), pp. 611-620; *abs. in Chem. Centbl.*, 1906, II, No. 18, p. 1458).—This method (*E. S. R.*, 9, p. 32) is not considered reliable on account of the slow and often incomplete evolution of carbon dioxide.

The determination of small quantities of iron, W. MCK. MARRIOTT and C. G. L. WOLF (*Jour. Biol. Chem.*, 1 (1906), No. 6, pp. 451-461).—The method proposed is based upon the color reaction which ferric salts show when treated with an alkaline thiocyanate. Acetone is recommended as a solvent and detailed directions are given for using the method in determining the iron in tissues and organic fluids, blood, urine, and inorganic substances.

Determining the crude fiber content of cocoa, W. LUDWIG (*Ztschr. Untersuch. Nahr. u. Genussmitt.*, 12 (1906), No. 3, pp. 153-159).—The crude fiber content of a number of samples of cocoa beans, cocoa shells, cocoa sprouts, and commercial cocoa and chocolate were determined with a view to detecting adulteration. Cocoa from which the fat was not extracted was found to contain 3.71 to 4.42 per cent crude fiber, fat-free cocoa 4.98 to 5.96 per cent, and cocoa shells 14.47 per cent. The differences between the cocoa and cocoa shells are so great that determining the crude fiber content may serve as a means for the detection of undue amounts of shells in the ground cocoa.

The estimation of crude fiber in cocoa goods, H. MATTHIES and F. MÜLLER (*Ztschr. Untersuch. Nahr. u. Genussmitt.*, 12 (1906), No. 3, pp. 159-161).—A comparison of methods.

Determining the digestible protein in feeding stuffs, A. STUTZER (*Jour. Landw.*, 54 (1906), No. 3, pp. 235-256, pl. 1).—The determination of digestible protein in feeding stuffs and related questions are critically discussed on the basis of analytical and other data.

In the author's opinion the separation of proteid from nonproteid compounds by the aid of copper hydroxid is satisfactory, and he considers it immaterial whether a solution of copper hydroxid is used or whether a copper salt is used and the copper hydroxid formed during the analysis. In both cases care should be taken to keep the liquid slightly acid. This is done by using a few cubic centimeters of strong alum solution when copper hydroxid is used as a reagent and by using a little less sodium hydroxid than is necessary for the complete change of copper sulphate into copper hydroxid when the copper salt is used as a reagent.

A simple method of separating proteids of feeding stuffs from peptones is considered desirable since by the present method the peptones are not entirely precipitated by copper.

The pepsin soluble protein in feeding stuffs may be determined by treating for 48 hours at blood temperature 2 gm. of material with 500 cc. of gastric ferment prepared according to the author's earlier directions or 250 cc. prepared by the method described in the investigation reported below, the acidity of the solution being increased until it reaches 1 per cent of hydrochloric acid.

Such artificial digestion differs from natural digestion and so the author believes that the pepsin pancreatic method of determining digestibility should receive further study.

New experiments have shown that the results obtained by the pepsin method are not always the same as those obtained by natural digestion. The need of additional experiments on the nitrogenous metabolic products of the feces is insisted upon.

Studies on simplifying the method of estimating pepsin soluble constituents of feeding stuffs, A. STUTZER, H. WANGNICK, and W. ROTHE (*Jour. Landw.*, 54 (1906), No. 3, pp. 265-272).—The conclusion is reached that the pepsin solution used in determining the digestible protein of feeding stuffs should be twice as strong as that commonly used, and directions are given for preparing such a reagent from fresh pig stomachs.

Estimating cellulose, lignin, and kutin in crude fiber, J. KÖNIG (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 12 (1906), No. 7, pp. 385-395).—An extension of work previously noted (E. S. R., 17, p. 436).

The optical rotation of gliadin in certain organic solvents, W. E. MATHEWSON (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 10, pp. 1482-1485).—The optical rotation of purified gliadin was studied, methyl, ethyl, and propyl alcohols of different strengths, phenol, paracresol, glacial acetic acid, and benzyl alcohol being used as solvents.

The attempt was also made to estimate the gliadin present in flour by digestion with phenol and polarization of the filtered extract. "The results obtained seem to indicate that a quite complete extraction of the gliadin is effected. It is possible, however, that more or less glutenin also dissolves in the phenol. The chief difficulty encountered is in the filtration of the mixtures."

"The fact that gliadin is soluble in phenol would seem to render possible an approximate determination of its molecular weight by the freezing-point method."

The technique of the quantitative estimation of albumen by means of the precipitin reaction, A. SCHULZ (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 12 (1906), No. 5, pp. 257-266).—The author's investigations led to the conclusion that proteids may be estimated quantitatively in food analysis by biological methods—that is, by means of the precipitin reaction. He describes in some detail his method of procedure and gives a summary of references to other articles on the subject.

Fermentation changes occurring in Muscovado sugars, F. WATTS and H. A. TEMPANY (*West Indian Bul.*, 7 (1906), No. 3, pp. 226-236, *dym.* 1).—The investigations showed that Muscovado sugar is liable to fermentative changes whereby the polarization is first increased and then decreased. These changes are considered due to micro-organisms. The rise in the polarization is due in part to the destruction of levulose and the subsequent fall to the destruction of dextrose and sucrose.

The estimation of cocoanut oil in butter fat, F. W. HARRIS (*Analyst*, 31 (1906), No. 368, pp. 353-360).—The presence on the market of cocoanut oil devoid of odor and practically neutral makes the determination of this substance of considerable importance. Different methods for this purpose have been tested in the author's laboratory for the past year.

According to the results obtained, the Bömer phytosterin acetate test (E. S. R., 16, p. 18) can not be used to distinguish between the adulteration of butter with cocoanut oil and with margarin. The method is expensive and tedious and is valuable only as a confirmatory test.

The Juckenack and Pasternack method (E. S. R., 16, p. 332) does not permit the detection with any certainty of less than 15 per cent of cocoanut oil.

By the Polenske method (E. S. R., 15, p. S50), which was subjected to careful and extensive examination, it is quite possible, in the opinion of the author, to detect the admixture of 10 per cent of cocoanut oil with a relative degree of certainty and to estimate fairly accurately an addition of 15 per cent. This method, which is simple and permits the determination of both the Polenske and Reichert-Meißl numbers in one operation, is recommended for general adoption.

The detection of cocoanut oil in butter, H. LÜHRIG (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 12 (1906), No. 10, pp. 588-592).—Studies were made of the method of Wijsmann and Reijst (E. S. R., 17, p. S34). With pure butter the second silver index was often lower than the first. The author therefore concludes that the method is of no value.

On the extraction of fat from feces and the occurrence of lecithin, J. H. LONG (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 6, pp. 704-706).—Comparative tests showed that when fat of feces was extracted by the paper-coil method higher results were obtained than by the shell extraction with sand. "No reason is apparent why such differences should obtain where sufficient time is given." The coil method "commends itself on account of ease in manipulation and complete extraction. A perfectly clear ether extract is obtained, which, after evaporation, again dissolves readily in ether."

The phosphoric acid in the fat was determined in the samples studied and would indicate an excretion of 3 to 5.5 gm. of lecithin per day. In later tests smaller amounts were found. "With our present knowledge of the distribution of lecithin in animal and vegetable foods it is somewhat difficult to account for such values." It is pointed out that further experiments are needed.

Gravimetric estimation of saltpeter in meat, C. PAAL and G. MEIERTENS (*Ztschr. Untersuch. Nahr. u. Genussmitt.*, 12 (1906), No. 7, pp. 410-416).—A comparison of methods led to the conclusion that the gravimetric (nitron) method of estimating saltpeter in meat and meat products gives sufficiently accurate results, and the data obtained by this method agree well with those obtained by the gas-volumetric method of analysis.

Note on the examination of maple products. The lead value, A. P. SY (*Jour. Franklin Inst.*, 162 (1906), No. 1, pp. 71, 72).—A modified method of estimating lead in maple sugars and maple sirups is proposed, lead acetate being precipitated by means of hydrochloric, nitric, and sulphuric acids, the lead sulphate, after the addition of alcohol, being removed by filtration and the lead determined as usual.

The quantitative estimation of ergot in flour, R. BERNHART (*Ztschr. Untersuch. Nahr. u. Genussmitt.*, 12 (1906), No. 6, pp. 321-340).—The method proposed depends upon the determination of the amount of chitin, a characteristic constituent of the ergot.

Practical guide for food chemists, G. PELLERIN (*Guide Pratique de l'Expert-Chimiste en Denrées Alimentaires*. Paris: Maloine, 1906, vol. 1, pp. 680; rev. in *Rev. Gén. Sci.*, 17 (1906), No. 16, p. 755).—This volume is designed as a laboratory manual for the guidance of food chemists, and, in addition to full descriptions of analytical processes and methods, contains numerous tables and similar data.

Yearbook of chemistry, R. MEYER ET AL. (*Jahrb. Chem.*, 15 (1905), pp. VII+595).—This is a review of the more important contributions to pure and applied chemistry during 1905. Biographical data are also included.

METEOROLOGY—WATER.

Monthly Weather Review (*Mo. Weather Rev.*, 34 (1906), Nos. 7, pp. 307-356, pls. 10, figs. 6, charts 8; 8, pp. 357-404, figs. 9, charts 6).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of July and August, 1906, progress of climatology throughout the world, recent papers bearing on meteorology, recent additions to the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 7.—Studies on the Thermodynamics of the Atmosphere—VI. The Water-spout Seen off Cottage City, Mass., in Vineyard Sound, on August 19, 1896 (illus.), by F. H. Bigelow; Climatology of Porto Rico from 1867 to 1905, inclusive, by W. H. Alexander (see p. 526); A New Form of Precision Barograph (illus.), by C. F. Marvin; Snow Rollers (illus.), by W. A. Bentley; Snow

Rollers at Mount Pleasant, Mich. (illus.), by R. D. Calkins; Progress of Meteorology in Australia; George J. Heck; Physical Societies and Journals; and Weather Bureau Men as Educators.

No. 8.—The International Symbols, by H. H. Clayton; The Meteorological Optics of Prof. J. M. Pernter (illus.), by R. W. Wood; Eiffel's "Etudes Pratiques;" Studies on the Thermodynamics of the Atmosphere—VII, The Meteorological Conditions Associated with the Cottage City Waterspout (illus.), by F. H. Bigelow; Variation in Temperature Over a Limited Area (illus.), by W. I. Milham; The First Daily Weather Maps from China (illus.), by C. F. Talman; What is Research; The International Seismological Association; and Astronomy versus Meteorology.

Climatology of Porto Rico from 1867 to 1905, inclusive, W. H. ALEXANDER (*Mo. Weather Rev.*, 3 $\frac{1}{2}$ (1906), No. 7, pp. 315-324).—This article supplements a previous report on the same subject, giving additional data regarding topography, which is based upon a bulletin of the U. S. Geological Survey, previously noted (E. S. R., 12, p. 795), and tabulated summaries of observations on temperature, rainfall, etc., at a number of places in Porto Rico, observations at San Juan, Canóvanas, and Perla being given in some detail.

The data show a very uniform temperature, with no excessive extremes, the annual range rarely being 50°. January shows the coldest mean temperature and August the hottest, the difference between the two, however, being only 5.1°. The extreme maximum temperature usually occurs in May. The mean temperature of the period from December to April is below the annual mean of the rest of the year above. The average daily range of temperature at San Juan is between 11 and 12°, although at interior stations a much greater range is recorded. The minimum daily temperature occurs about 5 a. m., the maximum from 10 a. m. to 2 p. m. The temperature decreases about 4° for each 1,000 ft. of elevation.

A well-defined dry season occurs from about November 20 to April 15, February being the driest month. The average number of rainy days is 194 at Canóvanas, 208 at San Juan, and 260 at Perla. The average rainfall for the east coast is 92 in., for the north and west sides 86, for the south side 57. The rainfall in general decreases westward to the middle of the Island and then rapidly increases. The south side is subject to long droughts, making irrigation necessary.

The steady northeast trade winds, light at night and fresh during the day, make the evenings cool and even the hottest days less oppressive. The island is out of the usual path of hurricanes and these are comparatively rare. Thunderstorms and hailstorms are infrequent and rarely violent.

Climatological atlas of India, J. ELIOT (*Calcutta*): *Indian Met. Dept.*, 1906, pp. XXXII, pls. 120; *rev. in Nature* [London], 75 (1907), No. 1941, pp. 241-244).—This atlas consists of 120 colored maps showing in great detail the distribution of the meteorological elements over the Indian Empire, with an introduction giving "a brief history of the progress of the work of meteorological observation in India and hence of the growth of the Meteorological Department, a list of the observatories contributing observations that have been utilized in the preparation of the atlas with their position and elevation, and a brief explanation of the charts."

The maps are based upon the results of observations during the first 25 years' operation of the Meteorological Department of India, beginning with the year 1875-76 and covering the incumbency of Sir John Eliot, and are classed as general, pressure and wind charts, temperature maps, humidity charts, cloud plates, rainfall maps, and storm track charts. The work is reviewed in *Nature* by J.

Hann, who refers to it as the most comprehensive statistical and scientific meteorological record in the world.

The effect of the sea upon climate (*Sci. Amer.*, 95 (1906), No. 8, pp. 130, 131).—Examples are briefly cited to show that "the enormous area of the sea has a great effect upon climate, but not so much in the direct way formerly believed. While a mass of warm or cold water off a coast must to some extent modify temperature, a greater direct cause is the winds, which, however, are in many parts the effect of the distribution of warm and cold water in the ocean perhaps thousands of miles away."

Sunrise, moisture, and growth, H. E. RAWSON (*Transvaal Agr. Jour.*, 4 (1906), Nos. 15, pp. 558-566, pls. 3, fig. 1; 16, pp. 743-754, pl. 1; 5 (1906), No. 17, pp. 140-148, figs. 2).—Observations and experiments on various plants are reported which lead to the conclusion that in regions of little cloud and excessive sunlight, as is the case at Pretoria, Transvaal, the early sun's rays are especially active in stimulating the growth of plants and indicate the desirability of so planting crops that they may utilize to the fullest extent such rays and be protected from excessive sunlight.

The author states the belief "that, besides rain, heat, soils, and all the well-recognized factors which enter into the question of growth, there are some subtle influences at work which have hitherto been little, or not at all, taken into account."

In commenting upon these conclusions H. Ingle and I. B. Pole Evans discuss the principal factors influencing plant growth in their bearing upon the deductions set forth, concluding that the results upon which the deductions are based "may be explained by the effects of temperature changes, and without attributing any occult influence to the morning sunshine per se. . . ."

"One important conclusion may be deduced from the considerations discussed in this review—that many plants would be benefited by being shaded from the hot midday sun, thus often preventing them from being heated above their maximum temperature for growth. . . ."

"It is probable that sunrise light contains a sufficiency of orange and yellow rays to produce rapid carbon assimilation, while the blue and violet rays, which tend to reduce growth, are relatively deficient.

"The unscreened plants, receiving such rays at a period when their temperature is favorable for the performance of their vital functions, thus have an advantage over their screened neighbors, which do not receive such strong light until later in the day, when their temperature is quickly raised to a point not so favorable for assimilation, but more favorable to the respiratory processes by which their tissues are oxidized and diminished."

Results of meteorological observations, 1905, R. HEINRICH, M. HABERLAND, and H. KÖNIG (*Arch. Ver. Freunde Naturgesch. Mecklenb.*, 59 (1905), 2. Abt., tables facing p. 252, chart 1).—Summaries are given of observations on temperature, pressure, precipitation, humidity of the air, cloudiness, duration of sunshine, etc., at the agricultural experiment station at Rostock; of observations on temperature, pressure, humidity, precipitation, cloudiness, etc., at the meteorological station at Neustrelitz; and on duration and photochemical properties of sunshine at Neubrandenburg.

Swedish meteorological observations, 1905, H. E. HAMBERG (*Met. Afttag. Sverige* [*Observ. Mët. Suéd.*], *K. Svenska Vetensk. Akad.*, 47 (1905), pp. X + 157).—This report is divided into 3 parts, (1) daily observations at 18 stations of the second order, (2) monthly and annual summaries of all the meteorological elements furnished by 39 stations of the second order, and (3) 5-day means of temperature at the 39 stations included in part 2.

Meteorology (*An. Estad. Mexicana*, 12 (1904), No. 12, pp. 27-42).—This report gives summaries of meteorological conditions as observed at the City of Mexico during 1904, and at a number of other places in the Republic of Mexico, with a discussion of seasonal variations in weather conditions.

Hourly meteorological and magnetic observations, Manila central observatory, 1904 (*Ann. Rpt. Philippine Weather Bur.*, 1904, pts. 1 and 2, pp. 208, charts 2).—This report records in part 1 the results during 1904 of hourly observations at the central observatory at Manila on atmospheric pressure, temperature, relative humidity, vapor tension, direction and force of the wind, and direction, form, and amount of clouds, and bi-daily observations on ozone; and in part 2, observations during the same period at the magnetical observatory on declination, horizontal force, inclination, and other disturbances, as measured by Mascart registering instruments.

Precipitation in North German river basins, G. HELLMANN (*Die Niederschläge in den Norddeutschen Stromgebieten*, Berlin: Dietrich Reimer, 1906, vols. 1, pp. V + 386 + 139, pls. 3, figs. 48, map. 1; 2, pp. VII + 722; 3, pp. VII + 872).—A review of this work in *British Rainfall, 1905*, refers to it as "the most remarkable compendium of rainfall data which has ever been published." It is a compilation, under the direction of the chief of the Royal Prussian Meteorological Institute of Berlin, of all available rainfall data up to the year 1900, the earliest records included dating back to 1715.

Observations at 4,000 stations are included. The data are discussed with reference to amount, frequency, and variation of rainfall.

A study of the longest records reduced to their average value for the 50 years 1851-1900 shows that the lowest mean annual rainfall in the region under consideration is about 18 in., the greatest about 58 in.

The average seasonal changes for the whole region are comparatively regular, February having as a rule the least rainfall and July the greatest, with a regular decrease following that month. Under the maritime conditions of the western part of the area, however, there is a tendency for the maximum to occur later in the year, in the extreme south and southeast to occur earlier. Over southern and central Germany the driest month is January, in the north-east February, and in the extreme north and northwest April. The rainfall of winter is 24 per cent of the annual total in the extreme west, diminishing steadily toward the east and south until it becomes less than 16 per cent at the sources of the eastern rivers. In the spring the rainfall increases from about 18 per cent of the total in the northwest and 20 per cent along the Baltic coast to more than 24 per cent in the valley of the Danube. The summer rainfall is 30 per cent of the total annual rainfall on the North Sea coast and 40 per cent in the heart of the continent. In autumn 30 per cent of the total rainfall occurs along the North Sea and Baltic coasts and 22 per cent in the central and southern states.

Leaving the mountainous regions out of account, the number of rainy days decreases from about 175 in the northwest of Germany to 135 or less in the southeast, the variations in different parts of Germany being somewhat irregular. In the north and west the months which have most frequent rains are October, November, or December, and the month having the least frequent rains April. In central Germany most frequent rains occur in July and least frequent usually in September. In the south June has most rainy days and November or January least.

In a study of variations in rainfall it was found that there was a greater tendency for a run of consecutive dry months than for a run of consecutive wet months. A relation was traced between variations in annual rainfall and sunspot frequency, each sunspot period including 2 rainfall maxima, closely

related to the turning points of the sunspot curve, the larger maximum of rainfall corresponding to the sunspot minimum, the smaller to the sunspot maximum. A 35 years' cycle corresponding to that deduced by Brückner for the whole of Europe seemed to be borne out by the data for North Germany.

A voluminous bibliography of literature relating to German rainfall is given.

Cirrus clouds and rain (*Science, n. ser., 24* (1906), *No. 624, p. 785*).—A brief note is given on studies by Vanderlinden at the Royal Observatory of Belgium at Uccle on the relation between the direction of movement of cirrus clouds and the subsequent occurrence of rain. The observations show in general that cirrus clouds "do not appear always to be the prognostics of rain which they have been said to be."

The Mount Rose weather observatory, J. E. CHURCH, Jr., (*Mo. Weather Rev., 34* (1906), *No. 6, pp. 255-263, figs. 9*).—An account is given in this article of the establishment, with the cooperation of the Nevada Academy of Sciences, the United States Weather Bureau, and the Nevada Agricultural Experiment Station, of a small observing station on the summit of this mountain which forms the northern apex of the Carson Range of the Sierra Nevada and is 10,800 ft. high. The peak is near Reno, Nev., and commands the Lake Tahoe and Truckee and Carson valleys. It was selected because it was believed "that an observatory here would be of service in furnishing data as to the constant air movements from the Pacific coast and in reporting approaching weather conditions to the districts farther east," and would furnish a valuable means of comparing the weather conditions of this high elevation with those of Reno in the valley, 6,268 ft. below, and of San Francisco to the southwest.

The records thus far made indicate a rather constant correspondence between fall in pressure and fall in temperature, and furthermore, that such fall precedes by several hours (24 to 36) the appearance of frost in the Truckee and Carson valleys below, thus furnishing a possible basis for frost prediction for these valleys.

In cooperation with the Nevada Experiment Station it is proposed to continue these frost studies and also to make investigations on precipitation and evaporation at this high altitude as well as of other problems having an agricultural bearing.

Water supply and sewerage (*Ann. Rpt. Bd. Health Mass., 37* (1905), *pp. 33-126, figs. 3, charts 3*).—This report contains as usual accounts of advice given to cities, towns, and public institutions regarding water and ice supply, sewerage and sewage disposal, pollution of ponds, streams, and other bodies of water, etc., the results of examinations of public water supplies and rivers, and water supply statistics, as well as articles on materials used for service pipes in Massachusetts, experiments on the removal of organisms from the waters of ponds and reservoirs by the use of copper sulphate, investigations concerning absorption and sedimentation of copper sulphate used as an algicide and concerning the bactericidal properties of copper and copper sulphate, experiments on the purification of sewage and water at the Lawrence Experiment Station in 1905, and examination of sewer outlets and of tidal waters and flats from which shellfish are taken.

Experiments with copper sulphate on ponds and reservoirs (pp. 207-287).—Experiments on a number of ponds and reservoirs with varying amounts of copper sulphate are reported, showing that the sulphate completely destroys certain kinds of organisms but has little or no effect on others. "The Cyanophyceæ, which are among the most troublesome of the organisms which cause disagreeable tastes and odors in the waters of ponds and reservoirs, can be removed by the application of copper sulphate in a quantity amounting approximately to 1 part of copper sulphate in 4,000,000 to 8,000,000 parts of water." Uroglena

of the Infusoria, which are very troublesome organisms in connection with water supplies, was removed by the use of copper sulphate at the rate of 1 part to 12,000,000 parts of water. The results, however, were not so satisfactory in case of Diatomaceae and green algae. Moreover, it appears that after repeated treatment with copper sulphate such organisms become less sensitive to its action. Under certain conditions copper sulphate seems to be very injurious to fish. In one case reported 1 part of sulphate in 5,000,000 parts of water destroyed large numbers of fish. There are conditions in both shallow and deep ponds and reservoirs under which the diffusion of the copper is very irregular and may remain for long periods locally concentrated.

The use of copper and copper sulphate as a bactericide, etc. (pp. 289-338).—Tank and reservoir experiments on the use of copper sulphate and metallic copper as a means of destroying bacteria, algae, etc., as well as studies of sedimentation of copper sulphate, its combination with mineral and organic matters, etc., are reported in this article. The results show among other things that while *Bacillus coli* and *B. typhosus* are occasionally killed by dilute solutions of copper, these organisms may live for many weeks in water containing not more than 1 part of copper sulphate in 100,000 parts of water. It is claimed that to insure the destruction of these germs 1 part of copper sulphate to 1,000 parts of water must be used, and such an amount of copper gives a strongly astringent taste to water. "In some instances, very dilute solutions of copper sulphate, or colloidal copper absorbed from contact with clean metallic copper, appear to have a decidedly stimulating effect on bacterial activity, causing rapid multiplication. . . . The two experiments made with sulphate of alumina and ferrous sulphate seem to indicate that these salts are about as efficient in destroying bacteria as copper sulphate."

In view of the uncertainty of the action of the copper sulphate under many conditions, it is stated "that the use of any method of sterilization which is not absolutely sure and effective is dangerous in ordinary hands, tending to induce a false feeling of security, and leading to the neglect of ordinary precautions which otherwise would be taken."

The use of copper in the purification of water, L. F. RETTGER and H. B. ENDICOTT (*Engin. News*, 56 (1906), No. 17, pp. 425, 426).—Experiments are reported from which the conclusion is drawn that "in the absence of appreciable quantities of organic matter (and an unusual amount of carbonates) and when the temperature is not too low (8-10° C.), copper sulphate has a strong germicidal action on *Bacillus coli*, *B. typhi*, the organisms of dysentery and Asiatic cholera, and on hog and fowl cholera bacilli. At 20° C. they are destroyed in dilutions of 1 to 400,000 and over, within a period of 24 hours. In the natural condition of water in reservoirs, etc., the action is in all probability much greater. When used intelligently, therefore, copper sulphate is a most valuable agent in the purification of drinking water. It has been shown frequently that small quantities of copper have no injurious action on man. Certain fish may be injured by it, but only in concentrations much greater than those which are necessary to destroy the typhoid organism, etc."

Sulphate of iron and caustic lime as coagulants in water purification, J. W. ELLMS (*Engin. Rec.*, 54 (1906), No. 16, pp. 439-441, fig. 1).—The use of these materials is discussed and their advantages explained. Of the latter the principal are rapid sedimentation in turbid waters and consequent elimination of plain sedimentation, diminished cost of purification, and a high degree of efficiency, especially in the case of the turbid waters of the Middle West.

Water softening and treatment, W. H. BOOTH (*London: Archibald Constable & Co., Ltd.*, 1906, pp. 324; *rev. in Chem. News*, 94 (1906), No. 2435, p. 46).

SOILS—FERTILIZERS.

Agricultural charts at the Congress of Applied Chemistry, Rome, 1906 (*Rev. Gén. Agron., n. ser., 1 (1906), No. 6-7, pp. 254-256*).—This is a review of a discussion of this subject by Proost.

The relation of plants to the composition of the soil and the association of certain plants with a particular kind of soil under natural conditions are discussed with reference to the utilization of such knowledge in the preparation of agricultural charts. A permanent committee of specialists in various lines was appointed to take this subject under consideration and to compile materials for the preparation of such charts.

On the relation between soils and the rocks from which they are derived, L. MILCH (*Mitt. Landw. Inst. Breslau, 3 (1906), No. 5, pp. 867-897*).—The studies here reported of soils produced under natural conditions at different stages of weathering from rocks of various kinds led to the conclusion that from the standpoint of soil formation the mineralogical constitution is the most important characteristic of the soil-forming rocks; that similar rocks may often in the course of weathering yield very dissimilar soils and vice versa, for example, such petrogenetically dissimilar rocks as granite and metamorphosed gneiss may at certain stages of decomposition yield like soils, and that the tendency is in all cases toward final uniformity of decomposition products and similar soils even when the original rocks were of very different character.

Oxidation in soils and its relation to productiveness, F. V. DARBISHIRE and E. J. RUSSELL (*Chem. News, 94 (1906), No. 2443, p. 137*).—A brief abstract of a paper read before the 1906 meeting of the British Association at York (see also E. S. R., 17, p. 536).

The phospho-humic compounds of the soil, J. DUMONT (*Compt. Rend. Acad. Sci. [Paris], 143 (1906), No. 3, pp. 186-189; abs. in Jour. Chem. Soc. [London], 90 (1906), No. 527, 11, p. 626*).—The author briefly reports the results of experiments in precipitating alkaline humate in the presence of solutions of phosphoric acid and phosphates and determining the composition of the precipitate.

He concludes from the results obtained that well-defined phospho-humic compounds are formed partly by the absorbent action of humus on the soluble phosphates in the soil solutions and partly by the reaction of these phosphates on the alkaline humates naturally produced by chemical action in cultivated soils.

Potassium humate absorbed 6.1 per cent of phosphoric acid when treated with a solution of this substance and larger amounts when treated with a solution of monocalcium phosphate. Humus precipitated in presence of dipotassium phosphate by a number of different acids contained about the same amount of phosphoric acid in each case and the percentage of this substance remained constant whatever the excess of phosphate added.

Studies on the soils of the northern portion of the great plains region. The second steppe, F. J. ALWAY (*Amer. Chem. Jour., 36 (1906), No. 6, pp. 580-594*).—The region referred to in this article "includes the whole eastern portion of the great plains, properly so-called, of Canada," of which the average elevation is 1,600 ft.

Analyses of samples of each foot of the soil down to a depth of 6 ft., taken at the Indian Head experimental farm, are reported, and while these analyses show the soil to be fertile, it is stated that there is nothing in the analytical results to explain the remarkable yields of wheat, oats, barley, peas, and potatoes which have been obtained.

The surface soil is rich in nitrogen (0.23 per cent in first foot) and both surface and subsoil are well supplied with potash (0.37 to 0.6 per cent) and phosphoric acid (0.14 to 0.18 per cent). The subsoil is also very rich in carbonates.

A study of moisture conditions in the soil leads to the conclusion that it is the moisture stored in the deep and permeable subsoil during the previous summer and not the frost of the preceding winter, as claimed by Sir Wm. Crookes and others, that is the cause of the high yields. The relative fertility of different areas of the soil seems to depend more upon the character of the subsoil as related to storage of moisture, etc., than upon that of the surface soil.

On the agricultural value of the cacao soils of St. Thomas and the Gold Coast, A. HÉBERT (*Bul. Soc. Chim. Paris, 3. ser., 35 (1906), No. 20-21, pp. 1039-1041; abs. in Jour. Chem. Soc. [London], 90 (1906), No. 530, II, p. 889*).—Physical and chemical analyses of a number of samples are reported. It is stated that in common with African soils in general the soils examined showed a marked deficiency of lime and potash, although nitrogen and phosphoric acid are usually present in sufficient amounts.

On the soils of the middle buntersandstein, E. BLANCK (*Landw. Vers. Stat., 65 (1906), No. 3-4, pp. 161-216, pl. 1*).—A geological and chemical study of this subject is reported, with a review of literature.

The results of examination of a number of soils of this group with reference to physical, chemical, petrographic, and mineralogical properties, and absorptive power for potash, phosphoric acid, and nitrogen, are reported, and the stages in the formation of such soils and their modification by the use of fertilizers are discussed.

Management of soils to conserve moisture, G. H. FAHYER (*U. S. Dept. Agr., Farmers' Bul. 266, pp. 30, figs. 7*).—This bulletin is a popular discussion of the subject of conservation of moisture in soils with special reference to semi-arid conditions, its preparation being suggested by the increasing interest taken in the question of dry farming in parts of the semi-arid West. It discusses briefly general principles, and deals more fully with the relation of drainage and tillage to soil moisture, conditions in the semi-arid regions and best method of controlling them, crops best suited to such regions, and the relation of organic matter to the conservation of moisture in soils.

Soil differences, J. A. BONSTEEL (*Cornell Countryman, 4 (1906), No. 3, pp. 68-70*).—This article briefly discusses differences in texture, structure, organic matter, moisture relations, and drainage of soils.

On Loew's theory regarding the lime-magnesia ratio in soils, J. C. DE RIJSTER DE WILDT (*Cultura, 18 (1906), Nos. 216, pp. 463-471; 217, pp. 505-513; 218, pp. 557-570; 219, pp. 650-666*).—Investigations on this subject are critically reviewed and the conclusion is reached that these investigations do not demonstrate that a definite relation between lime and magnesia is necessary to normal nutrition of plants, although it is not denied that a relation may exist. Further investigation of the subject is required.

The removal of black alkali by leaching, F. K. CAMERON and H. E. PATEN (*Jour. Amer. Chem. Soc., 28 (1906), No. 11, pp. 1639-1649, figs. 5; abs. in Chem. Abs., 1 (1907), No. 1, pp. 79, 80*).—This article reports analyses and percolation tests with 2 samples of black alkali soils, one from North Yakima, Wash., the other from Fresno, Cal.

The analyses showed that these samples of alkali contained besides the soluble carbonates notable quantities of sodium sulphate with much smaller amounts of other sulphates and chlorids. One hundred grams of each soil was placed in a paraffined brass tube connected below with a short section of a Pasteur-Chamberland filter tube, and distilled water was allowed to percolate through the soil

under a constant pressure of $6\frac{1}{2}$ ft. The volume and time of flow of each percolate was measured, its electrical conductivity was taken, and its chemical composition was determined.

The conclusions reached from the results obtained were as follows:

"(1) Neutral salts such as the chlorids in the presence of carbonates can be comparatively readily and completely leached from the soil.

"(2) With continued leaching of soils containing 'black alkali' there is an increase in the rate at which percolation takes place, due probably to the reduction of the amount of alkali present and its effect on the physical structure of the soil.

"(3) With continued leaching there is a comparatively rapid reduction of normal carbonates in the soil water, due in large measure to conversion into bicarbonates.

"(4) Bicarbonates are rapidly removed at first and then continue to be slowly removed in the soil water in very small amounts, diminishing so slowly as to be practically constant for an indefinite period.

"(5) Soils containing 'black alkali' can be reclaimed by leaching, but the time and the amount of water required are probably much greater than in the case of 'white alkali.'"

The decrease of soil temperature with elevation in the Prologh Mountains in Dalmatia, F. VON KERNER (*Met. Ztschr.*, 23 (1906), No. 9, pp. 421, 422).—Decreases of from 0.38 to 0.75° for each 300-meter increase in elevation were observed.

Notes on carbon bisulphid, its action on the lower plant organisms as well as the fertility of soils, B. HEINZE (*Centbl. Bakt.* [etc.], 2, Abt., 16 (1906), No. 10-13, pp. 329-358; *abs. in Chem. Centbl.*, 1906, II, No. 8, p. 699).—Previous investigations on this subject are reviewed and experiments by the author are reported which indicate that the beneficial effects observed in the case of applications of carbon bisulphid to the soil may be in a measure obtained by green manuring with mustard, which supplies to the soil certain sulfur carbon derivatives which have a similar action to carbon bisulphid in promoting the activity of nitrogen-fixing organisms. A bibliography of 24 references to the literature of the subject is appended.

The utility of earthworms in agriculture, E. DE RIBAUCOURT and A. COMBAULT (*Abs. in Rev. Gén. Agron.*, n. ser., 1 (1906), No. 9, pp. 374-384).—This is a review of observations and investigations showing the important part which earthworms (*Lumbricus*) play in improving the chemical and physical properties of soils.

Some contributions to the microbiology of soils, B. HEINZE (*Centbl. Bakt.* [etc.], 2, Abt., 16 (1906), Nos. 20-21, pp. 640-653; 22-23, pp. 703-711; *abs. in Chem. Centbl.*, 1906, II, No. 10, p. 903; *Jour. Chem. Soc.* [London], 90 (1906), No. 527, II, pp. 625, 626).—The literature of the fixation of the free nitrogen of the air by lower organisms and the assimilation of free nitrogen by algae is reviewed.

The author's experiments indicate that in general pure cultures of the algae did not fix nitrogen in large amounts, although there was rapid fixation when the cultures of the algae were inoculated with *Azotobacter* or other nitrogen-fixing organisms. The author concludes in general that the importance of algae in relation to nitrogen fixation of the soil depends mainly upon the fact that they furnish a valuable and readily available supply of carbon compounds for the assimilation of the nitrogen-fixing organisms, especially *Azotobacter*.

Conditions affecting legume inoculation, K. F. KELLERMAN and T. R. ROBINSON (*U. S. Dept. Agr., Bur. Plant Indus. Bul.* 100, pt. 8, pp. 15, pls. 2).—The bulletin records the results of greenhouse studies on soils from different

parts of the United States, of the relation of lime, character of soil solution, heavy inoculation, aeration, and associative action of bacteria on the efficiency of legume inoculation. The results are thus summarized:

"(1) Lime is of decided benefit in obtaining successful inoculations of legumes in some soils. These soils often show an acid reaction to litmus.

"(2) Soil extracts serving as culture media often indicate the probable success of inoculating a leguminous crop. This, however, may not always hold true.

"(3) At least during the first season's growth no general cross-inoculation takes place. Bacteria from one host may, however, inoculate a physiologically related species.

"(4) Heavy inoculation by a pure culture increases nodule formation if the soil solution is enriched by the excess of culture medium; however, in a favorable soil a light inoculation well distributed is as effective.

"(5) Thorough aeration is favorable to nodule formation.

"(6) Whether in a synthetic medium or a natural soil solution, the functions of a bacterium are influenced by the associative or competitive action of the various groups of organisms with which it comes in contact, as well as by the nature of the culture material."

Experiments with nitrogen-assimilating bacteria, A. BRUTTINI (*Bol. Quind. Soc. Agr. Ital.*, 11 (1906), No. 18, pp. 658-664).—The work of other investigators on this subject is reviewed, and experiments by the author with Moore's cultures are reported. These show that while the cultures were effective when the soil was not naturally inoculated, so few cultivated Italian soils are in this condition as to render the practical value of artificial inoculation doubtful.

On some new nitrogen bacteria with autotrophic habits of life, H. KASERER (*Ztschr. Angew. Chem.*, 19 (1906), No. 40, p. 1681).—This is a brief note on a paper on this subject presented at the recent meeting of the German Association of Naturalists and Physicians.

The author isolated and describes two organisms which oxidize ammonia compounds. The first, to which the name *Bacillus nitrator* is given, transforms ammonia compounds directly into nitrate without the intermediate formation of nitrite; the other, *Bacillus azotofluorescens*, oxidizes ammonia, setting free nitrogen without the intermediate formation of either nitrite or nitrate.

On the chemical processes involved in the assimilation of elementary nitrogen by Azotobacter and Radiobacter, J. STOKLASA (*Ztschr. Ver. Deut. Zuckerindus.*, 1906, No. 698, pp. 815-825).—Culture experiments with these organisms, singly and combined in various culture media to determine their capacity for fixing free nitrogen and the conditions which favor this process are reported. In a medium containing 20 gm. of mannite and 0.5 gm. of potassium phosphate per liter *Azotobacter* assimilated 75 mg. of nitrogen per liter in 10 days, 90 mg. in 15 days, and 125 mg. in 20 days. *Radiobacter* cultures showed practically no gain in nitrogen, and mixtures of the two organisms showed less gain than *Azotobacter* alone. Glucose proved a better source of carbon than mannite, provided a little calcium or sodium carbonate was added to the medium. In a glucose medium *Azotobacter* fixed 180 mg. of nitrogen per liter in 15 days, in which time the glucose was entirely used up. On the average 165 gm. of glucose was required for 1 gm. of nitrogen assimilated. No soluble nitrogen compounds were formed in the cultures. The bacterial mass contained 10.2 per cent total nitrogen and 8.6 per cent pure ash, the latter containing 62.35 to 58 per cent of phosphoric acid. The nitrogen and phosphorus in the bacterial mass was mainly in the form of nucleo-proteid and lecithin. Measurements of the carbon dioxide evolved showed a very large evolution of this gas, the highest production being observed at from the fourth to the sixth

day. The rate of evolution was 1.2729 gm. of CO_2 per gram of dry matter in the bacterial mass, in 24 hours, a rate much higher than that found in the case of *Bacterium hartlebi* (0.6 gm.) and *Clostridium gelatinosum* (0.18 gm.).

The author found carbon dioxide, hydrogen, alcohol, and lactic, acetic, and formic acids to be produced by the breaking down of the mannite or glucose of the media and he believes that these changes are brought about in presence of an abundance of oxygen by the action of a glycolytic enzyme which he has isolated from cultures of *Bacterium hartlebi*.

The fixation of atmospheric nitrogen (*Engineer* [London], 102 (1906), No. 2647, pp. 285, 286).—A summary is here given of papers and a discussion by Nernst, Foerster, Le Blanc, Klaudy, Frank, Brode, and other electro-chemists at the thirteenth annual meeting of the German Bunsen Society, held at Dresden May 20 to 23, 1906, the fixation of atmospheric nitrogen being the special subject selected for discussion at this meeting.

The principal papers presented and discussed were as follows: Two papers on the general subject of the fixation of atmospheric nitrogen, by Foerster and Le Blanc; the equilibrium and reaction velocity ratios for nitric oxid formation, by Nernst; technical methods for carrying out the combustion of nitrogen, by F. Foerster; and technical methods for converting the nitrous gases into nitric acid and its salts, by Klaudy.

Researches on the direct synthesis of nitric acid and of nitrates from their elements at ordinary temperature, M. BERTHELOT (*Compt. Rend. Acad. Sci.* [Paris], 142 (1906), No. 25, pp. 1367-1379; *Ann. Chim. et Phys.*, 8, ser., 9 (1906), Oct., pp. 145-163; *abs. in Jour. Soc. Chem. Indus.*, 25 (1906), No. 14, p. 695; *Chem. Abs.*, 1 (1907), No. 1, p. 22; *Bul. Soc. Chim. Paris*, 3, ser., 35 (1906), No. 23, pp. 1221, 1222).—The author reports studies of the effect of silent discharges of the induction coil on mixtures of nitrogen and oxygen in presence of water or alkali hydroxid operating on a stream of gas passing through the apparatus and also on a fixed contained volume of gas.

"The primary current was 12 amperes at 6 volts, and the poles of the coil were 20 mm. apart. The coil was used both with and without a condenser. It was found that the high tension of the coil was necessary (no effect was produced by connecting the apparatus directly with the public alternating supply at 100 volts), but that the condenser was practically without influence. In the circulation experiments, 0.0192 gm. of nitric acid per hour was produced from half a liter of air, or about 14 per cent of the total amount possible. No effect was produced by substituting alkali hydroxid for water in the apparatus. Neither ammonia nor nitrous acid was produced. In the constant volume experiments, whether the gases were mixed in the proportions $\text{N}_2 : \text{O}_2$ or there was excess of nitrogen, reaction occurred to the (practically) complete disappearance of oxygen; and here, also, no other reaction than the direct formation of nitric acid took place. In these experiments, measurements of pressure and time showed an acceleration of the reaction after the beginning, followed by a gradual retardation as the pressure (and hence the concentrations of the reacting gases) diminished, so that the theoretical completion of the reaction would occur only after infinite time. It is to be remembered that the reactions here concerned—

are exothermic, and differ in this from the formation in the arc of nitric oxid or nitrogen peroxid from their elements."

The industrial utilization of the nitrogen of the air, C. FUSCHINI (*Rivista*, 4, ser., 12 (1906), No. 19, pp. 435-441).—This is a review of a report by O. N. Witt which has already been noted (*E. S. R.*, 17, p. 746).

The electrical production of nitric acid from the elements of the air, L. GRANDEAU (*Ann. Sci. Agron.*, 3. ser., 1 (1906), No. 1, pp. 1-60, figs. 29).—The works, apparatus, and methods employed at Notodden, Norway, are quite fully described. This article is also published as a separate.

Oxidation of nitrogen by silent discharges in atmospheric air, E. WARBURG and G. LEITHÄUSER (*Ann. Phys.*, 4. ser., 20 (1906), No. 4, pp. 743-750; *abs. in Amer. Jour. Sci.*, 4. ser., 22 (1906), No. 131, p. 462).—The authors report a series of experiments from which they conclude that " (1) nitrose gases in the presence of ozone are easily absorbed by dilute soda lye; (2) with silent brush discharges from the positive terminal sphere in atmospheric air, at the room temperature, independently of the moisture of the air, 10 liters of NO is oxidized by an ampere hour; (3) the oxidized quantity of nitrogen mixture increases with increasing temperature and then decreases with the formation of the ozone; (4) a quantity of N_2O_4 , indicating 1 cc. NO in 1,500 cc. lessens the formation of ozone when the silent discharge occurs in atmospheric air."

Nitric acid and other spark reactions (*Jahrb. Elektrochem.*, 11 (1904), pp. 610-615).—The literature especially of investigations relating to the preparation of nitric acid from the atmosphere is reviewed.

A domestic supply of nitrogen, N. CARO (*Ztschr. Angew. Chem.*, 19 (1906), No. 37, pp. 1569-1581, figs. 5).—Statistics of production and consumption of nitrogen compounds are given, and the apparatus and processes used and the commercial success attained in the manufacture of nitrogen compounds, especially calcium cyanamid, potassium cyanid, and nitrates, are described. It is stated that the cost of production in these methods is still too high to enable the products to compete successfully with the natural supplies except possibly in special cases of unusually cheap power, etc.

Nitrogen lime, its use and action (*Deut. Landw. Presse*, 33 (1906), No. 48, pp. 405, 406; *Landw. Wchubl. Schles.-Holst.*, 56 (1906), No. 40, pp. 602, 603).—A brochure on this subject by Münzinger of the Darmstadt experiment station is briefly reviewed.

Apparatus for the preparation of lime nitrogen and ammonium sulphate according to the methods of the Cyanid Company of Berlin (*Deut. Landw. Presse*, 33 (1906), Nos. 76, p. 606, figs. 4; 79, p. 631, fig. 1).—The construction and operation of the furnaces and other apparatus used in preparing these compounds by the Frank and Caro and Siemens processes are described and illustrated.

The making of sulphate of ammonia (*Amer. Fert.*, 25 (1906), No. 4, pp. 5-10, figs. 3).—This article discusses briefly the value of ammonia in agriculture and describes the methods used in preparing ammonium sulphate by the destructive distillation of coal.

Treatment of vinasse and molasses for recovery of nitrogenous matter after removal of potash, VASSEUX (*Bul. Assoc. Chim. Sucr. et Distill.*, 23 (1906), No. 12, pp. 1381, 1382; *abs. in Jour. Soc. Chem. Indus.*, 25 (1906), No. 16, p. 823).—The author points out that while the nitrogenous matter contained in molasses is more valuable than the potassium salts present, the former is generally lost by incineration during the process of working up the saline matter. He proposes the following method for its recovery: The vinasse is concentrated and treated with sulphuric acid, thus converting the potash into sulphate, which crystallizes out. The mother liquors are then evaporated to dryness in an apparatus of special construction, yielding a residue containing from 5 to 7 per cent of nitrogen and 6 to 7 per cent of potash.

On the practical value of lime nitrogen as a fertilizer, W. VON KNIERIM

(*Rigasche Indus. Ztg.*, 1906, p. 204; *abs. in Chem. Ztg.*, 30 (1906), No. 88, *Repert. No. 41*, p. 370).—The author reviews other investigations on this subject and reports experiments during 1905 with oats to test the fertilizing value of lime nitrogen as compared with nitrate of soda. The material was applied 10 days before seeding and cultivated in to a depth of 3 to 5 in. The lime nitrogen gave somewhat better results than nitrate of soda, both as regards yield of grain and of straw.

Preliminary experiments with a cyanamid compound as a nitrogenous fertilizer, F. T. SHUTT and H. W. CHARLTON (*Proc. and Trans. Roy. Soc. Canada*, 2. ser., 11 (1905-6), *Sec. III*; *Chem. News*, 94 (1906), No. 2444, pp. 150-152).—Experiments to determine the effect of calcium and potassium cyanamido-carboxylate on the germination or vitality of seed wheat and peas, and the rate at which these compounds are nitrified when present in the soil in various proportions, are reported.

The results in the first case led to the conclusion "that the presence of the cyanamid compounds in amounts equivalent to 5 mg. or less of nitrogen per 100 gm. of soil would not prove injurious to the germination of seed. Toxic effects were markedly noticeable, however, with amounts between 10 and 20 mg. per 100 gm. soil, while still larger quantities proved fatal. The potassium compound appears to be more injurious in its action on the life of the seed and of the young plants than the calcium salt."

In the second case the results indicate "that with the increase in the amount of the cyanamid compound there is a concomitant decrease in the rate of nitrification. This is probably due, as already indicated, to a toxic action upon the nitrifying organisms by the cyanamid compound, which action would naturally be increased the larger the application. On the other hand, it may in part be due to denitrifying changes leading to the loss of nitrogen in the free state.

"The conversion of the nitrogen of the cyanamid into available forms is, most probably, under favorable conditions, continuous, though not uniformly so. The first stage may be considered possibly as purely chemical, since water at ordinary temperatures converts the nitrogen of cyanamid into ammonia. The further changes being brought about through the agency of living organisms are necessarily slower and will be regulated by many factors, prominent among which, as we have observed, is the proportion of the cyanamid compound present in the soil."

Fertilizer experiments in 1905 with calcium cyanamid in comparison with other nitrogenous fertilizers and liquid manure, G. CARUSO (*Atti R. Accad. Econ. Agr. Georg. Firenze*, 5. ser., 3 (1906), No. 2, pp. 228-238).—Comparative tests of calcium cyanamid, ammonium sulphate, sodium nitrate, and liquid manure on corn and beans grown on coast lands which were well provided with fertilizing constituents are reported. Notwithstanding the fact that the soil was in a good state of fertility, all of the nitrogenous fertilizers produced an increase in crop. The order of efficiency was calcium cyanamid, ammonium sulphate, sodium nitrate, and liquid manure. The calcium cyanamid increased not only the yield of grain, but also its weight per bushel. The high efficiency of the calcium cyanamid is attributed partly to the lime which it contains, supplying a deficiency in the soil, and to the more lasting and uniform effect of the nitrogen it contains. The calcium cyanamid used in these experiments furnished nitrogen at one-fifth less cost than sodium nitrate.

The decomposition of calcium cyanamid when used as a medium for bacteria, R. PEROTTI (*Arch. Farmacol. Sper. e Sci. Aff.*, 5 (1906), No. 9, pp.

385-394, pl. 1).—In previous experiments the author has shown that in certain concentrations calcium cyanamid has a decided antiseptic action. In lower concentrations, however, a considerable growth of bacterial flora takes place.

In the experiments here reported, it was shown that by the action of microorganisms ammonia was formed from the calcium cyanamid, thus agreeing in general with the results obtained by Löhnis (E. S. R., 17, p. 345). It is not considered, however, that this action is a result of a specific function possessed by a determinate form, but is a part of the great process of ammonia production which goes on in soils as a result of the action of innumerable forms of microorganisms. The author's results differ from those of Löhnis in that he was unable to obtain the complete decomposition of the calcium cyanamid reported by Löhnis in some cases. This discrepancy is thought to have been due to the fact that Löhnis used a method of preparing his liquid media (sterilization by heating in a current of steam) which probably resulted in the formation of dicyandiamid, which very likely is more readily converted into ammonia than the calcium cyanamid. This is a point which demands further investigation.

Experiments on the fate of the nitrogen of green manures in light sandy soils, VON SEELHORST (*Mitt. Deut. Landw. Gesell.*, 21 (1906), Nos. 28, pp. 289-293; 29, pp. 295-299).—The details of experiments on sand in large tanks to determine the balance of nitrogen with different methods of green manuring for various crops are reported. The results, while not considered conclusive, indicate that the greater part of the rather large amount of the nitrogen of green manures which is not utilized by crops on sandy soils is carried away in the drainage, while a smaller proportion is lost by denitrification, especially on soils dried out by growth of a crop of cereals.

Field experiments at Jarville with phosphatic and nitrogenous fertilizers, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 12 (1906), No. 37, pp. 325-327).—The results of a series of experiments are briefly summarized. These show that bicalcium and monocalcium phosphate gave practically the same results and were about equally profitable. Fine ground mineral phosphates gave much lower yields. Nitrogenous fertilizers in general were about four times as effective in increasing the yield as potassic and phosphatic fertilizers.

Norwegian nitrate and the culture of corn, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 12 (1906), No. 38, pp. 360, 361).—A comparison of normal and basic nitrate of lime, nitrate of soda, and nitrite of lime, each applied to corn at a rate of 45 kg. of nitrogen per hectare (40 lbs. per acre) is reported, the results showing that the nitrates of lime were about as efficient as the nitrate of soda and the nitrite of lime somewhat more efficient.

Nitrite and nitrate as a top-dressing for corn, L. GRANDEAU (*Jour. Agr. Prat.*, n. ser., 12 (1906), No. 40, pp. 421, 422).—This is a brief summary of experiments during 1906 at Pare des Princes, in which nitrite from Notodden, Norway, and nitrates of soda and of lime were compared. The results show that nitrites applied broadcast at the time of seeding were not injurious and had a fertilizing value for corn equal or superior to nitrate of soda.

A further contribution to the question of the influence of fertilizing with straw on the yield, C. VON SEELHORST (*Jour. Landw.*, 54 (1906), No. 3, pp. 283-300; *abs. in Jour. Chem. Soc.* [London], 90 (1906), No. 528, II, p. 702).—Further tank and pot experiments on this subject are reported (see also E. S. R., 16, p. 33) which were undertaken to study the effect of the depth of application of straw and strawy manure and of variations in aeration, moisture, and character of the soil on the loss of nitrogen. The experiments were made in tanks $1\frac{1}{2}$ meters deep and 1 meter in diameter sunk in the earth, and in ordinary pots.

The results show that straw and strawy manure in absence of nitrate of soda caused a reduction of yield dependent upon the character of the soil, being quite marked on poor soils and very small on more fertile soils. The loss is generally confined to the first year, except in case of poor, sandy soils. With loam soils treated with nitrate of soda there is a slight increase the second and third years after application of straw.

The results of several years' field experiments with fertilizers, TACKE (*Jahrb. Deut. Landw. Gesell.*, 20 (1905), pp. 36-46, fig. 1).—Various practical conclusions which, however, are applicable mainly to German conditions, are drawn from the results summarized.

The use of fertilizers in extensive culture with reference to geological formation and soil analysis, H. BOCK ET AL. (*Jahrb. Deut. Landw. Gesell.*, 20 (1905), pp. 46-55).—Various general views on this subject are presented in their application to German conditions.

On the relative value of different phosphates, D. N. PRIANISHNIKOV (*Landw. Vers. Stat.*, 65 (1906), No. 1-2, pp. 23-54, pls. 9, fig. 1; *abs. in Chem. Abs.*, 1 (1907), No. 1, p. 79).—In continuation of previous experiments (E. S. R., 13, p. 934) sand culture tests were made of leached ashes, bone meal, Thomas slag, phosphorite, and superphosphate on tobacco, buckwheat, oats, barley, millet, lupines, Robinia, peas, mustard, and sugar beets. The tests were designed to determine not only the relative fertilizing effect of these phosphates, but also the factors affecting their assimilability.

The results show in general that the phosphoric acid of leached ashes, especially those of straw, is readily assimilable; the phosphoric acid of bone meal showed a relatively good assimilability, the yields with this form of phosphoric acid being, as a rule, not lower than 50 to 60 per cent of those with soluble phosphoric acid. Poorer results were obtained in presence of calcium carbonate and ferric hydrate in the soil. The influence of the latter was, however, overcome when ammonium salts were also applied. The tests of raw phosphates indicated that their assimilability was more influenced by the character of the crop than by the properties of the phosphate. In soil cultures acidity is of course a determining factor.

The assimilation of phosphates is greatly modified by the presence of ammonium salts, so much so that even the most insoluble phosphates are rendered available to all plants. This is ascribed to the physiological acidity of such salts as ammonium sulphate and ammonium chlorid. When experiments are made with soils this action is modified by nitrification, which, for example, makes two free acids out of a neutral salt like ammonium sulphate. The action is further modified by the amount of basic substances present in the soil.

On the stability of Thomas-phosphate-ammonium-lime, M. SCHMOEGER (*Ztschr. Angew. Chem.*, 19 (1906), No. 40, p. 1681).—This is a note on an article presented at the recent meeting of the German Association of Naturalists and Physicians, in which experiments are reported showing that there is a large loss of nitrogen when this mixture is allowed to stand for some time.

The behavior of bone and mineral superphosphate in soils and the modifications which they undergo, C. MONTANARI (*Stat. Sper. Agr. Ital.*, 39 (1906), No. 4, pp. 323-339).—Other investigations on this subject are reviewed and experiments by the author on 8 soils of different kinds are reported.

Basic slag (*Mark Lane Express*, 95 (1906), No. 3912, pp. 299, 300, figs. 2).—A summary is given of information relating to the history, manufacture, qualities, and use of this material.

A field experiment to test the merits of phosphate, potash, and nitrogen

on a fine sandy loam of peculiar character, E. HERSEY (*Bul. Busscy Inst.*, 3 (1906), pt. 5, pp. 113-119, *dgms.* 2).—Comparative tests of various fertilizing materials on corn grown on a fine sandy loam which was well supplied with capillary water are reported, showing a marked superiority of the bone over all other fertilizing materials.

The use of leucitic rocks as fertilizer, E. MONACO (*Staz. Sper. Agr. Ital.*, 36 (1903), No. 7, pp. 577-583; 37 (1904), No. 11-12, pp. 1031-1034; 39 (1906), No. 4, pp. 340-349).—Studies of the amount of potash, lime, etc., dissolved by water and other solvents from various leucitic rocks, soils, etc., are reported.

Process for the utilization of potash minerals, insoluble and soluble with difficulty, for fertilizing purposes, C. PLOCK and H. MEHNER (*Jour. Soc. Chem. Indus.*, 25 (1906), No. 18, p. 898).—Brief reference is made to a German patent of a process providing for the use of such minerals, especially "phonolith" waste, in place of sand as an addition to molten Thomas slag.

Potash salts (*Mark Lane Express*, 95 (1906), No. 3915, pp. 383, 384, *figs.* 2).—Information regarding the mining and use of potash salts in agriculture is summarized.

The peat and marl deposits of the Rederang and Moorsee basins, U. STEUSLOFF (*Arch. Ver. Freunde Naturgesch. Mecklenb.*, 59 (1905), 2. Abt., pp. 147-210, pl. 1).—The extent and character of these deposits are described in some detail.

Origin, composition, and utility of fertilizing materials, R. J. DAVIDSON and W. B. ELLETT (*Virginia Sta. Bul.* 163, pp. 48).—This is a compilation of information on the composition, value, and use of farm manures and fertilizers, including also a discussion of home mixing and formulas for fertilizer mixtures for various crops.

Analyses of commercial fertilizers and Paris green, J. E. HALLIGAN (*Louisiana Stas. Bul.* 87, pp. 50).—This bulletin gives the results of analyses of 2,508 samples of fertilizing materials and 73 samples of Paris green inspected during the season of 1906. The results of the inspection of fertilizers show a general tendency toward excess of phosphoric acid and deficiency of nitrogen in mixed goods, as well as in tankage. The samples of cotton-seed meal examined were very variable in composition. The acid phosphates and bone meals as a rule exceeded the guaranties.

AGRICULTURAL BOTANY.

The sexuality of cotton, W. L. BALLS (*Yearbook Khediv. Agr. Soc. Cairo*, 1905, pp. 197-222, pls. 9).—Investigations have been begun by the author on heredity in cotton. The present paper includes the history of the cotton flower and the early stages of the embryo, while changes in the seed and development and maturation of the fiber will be discussed in a subsequent publication.

The cytology of the sex cells is described at considerable length, and a brief account is given of the development of the cotton fiber. This begins before fertilization is accomplished, but whether it is entirely independent of pollination or not has not been definitely determined. Contrary to previous reports, the development of the fiber is not from subepidermal cells of the outer integument, as is usually stated, but by simple linear extension of the epidermal cells, the cotton fiber thus being a simple epidermal hair.

The mechanism of carbon assimilation in green plants, F. L. USHER and J. H. PRIESTLEY (*Proc. Roy. Soc. [London]*, Ser. B, 77 (1906), No. B 518, pp. 369-376; 78 (1906), No. B 526, pp. 318-327).—A series of experiments has been carried on to determine the nature of the first stages in the assimilation of carbon from carbon dioxide by green plants. It has been shown that carbon

dioxid may be decomposed by uranium acetate, the decomposition resembling that which takes place within the plant. This is accompanied by the formation of formaldehyde, which is rapidly converted into some physiological inert substance, and peroxid, which is decomposed with the evolution of gaseous oxygen.

Experiments on the mechanism of the evolution of oxygen from the green plant suggest the presence of a catalyst, probably an enzym, and this enzym has been found in the foliage leaves of plants representing 46 natural orders of vascular cryptogams and phanerogams. It also occurs in etiolated leaves and potato tubers, appearing to be associated with amyloplasts, whether possessing chlorophyll or not.

Experiments with *Spirogyra* have shown that a starchless filament will contain starch within 3 minutes after exposure to light, and it is believed that starch is not elaborated within the cell until the supply of that nutrient is in excess of the cell's requirements. It would therefore seem that there must be some arrangement for the rapid removal of formaldehyde, and for this reason it is useless to attempt to find formaldehyde in healthy assimilating leaves.

Summarizing their conclusions, the authors state that photolysis of carbon dioxid may take place outside the plant in the absence of chlorophyll, providing one of the products is removed. The normal products of photolysis are hydrogen peroxid and formaldehyde, though under certain conditions formic acid may be formed. In the plant the decomposition of the hydrogen peroxid is provided for by a catalytic enzym of general occurrence, and the condensation of the formaldehyde is dependent on the healthy condition of the protoplasm.

In continuation of their investigations, reported in the second paper, the authors conclude that photolytic decomposition of aqueous carbon dioxid can take place in the presence of chlorophyll independently of vital or enzym activity, provided the necessary physical and chemical conditions are strictly adhered to. The products of the decomposition are formaldehyde and hydrogen peroxid, formic acid being an intermediate product. It is possible to reconstruct the process of photosynthesis outside the green plant, so far as the production of formaldehyde and oxygen is concerned, by introducing a suitable catalytic enzym into the system, and for the production of oxygen and starch by introducing, in addition to the enzym, certain kinds of nonchlorophyll-bearing living protoplasm.

There is direct experimental proof that formic acid is a product of the photolytic decomposition of carbon dioxid in the presence of an inorganic uranium salt. Formaldehyde has not been isolated and identified in the case of decomposition by the inorganic uranium salt, but a study of the reactions favors the view that it is formed as a transitory intermediate product.

Variations in chlorophyll assimilation under the influence of light and temperature, W. LUBIMENKO (*Compt. Rend. Acad. Sci. [Paris]*, 113 (1906), No. 17, pp. 609-611).—In continuation of previous investigations on the sensitiveness of the chlorophyll of plants tolerant and intolerant to shade (E. S. R., 17, p. 651), the author reports briefly on experiments to determine the effect of light and heat on the decomposition of carbon dioxid by plants.

In his experiments leaves of a number of species of tolerant and intolerant trees were exposed for 15 minutes to full sunlight, the rays falling upon the leaves parallel to their surface and at 45° and 90° angles of inclination. The temperatures were held for different lots at 20°, 25°, 30°, 35°, and 38° C. and the carbon dioxid decomposition determined in each case. Among the plants studied were fir, spruce, yew, and linden as tolerant species, and pine, black locust, and white birch as intolerant to shade.

When the minimum of illumination, parallel rays, was studied it was found that the carbon dioxide assimilation increased with the increase in temperature. Where the illumination was at 45°, which corresponds with average illumination, the increase was regular and the temperature rose until an optimum was reached, after which the decomposition fell off more rapidly for the tolerant than for the intolerant species. Similar results were obtained when the leaves were illuminated vertically, the decrease beyond the optimum falling more rapidly than when less illuminated.

Summarizing his investigations, the author claims that under the conditions of his experiments heat and light facilitate carbon dioxide decomposition, that there is an optimum for each beyond which the assimilative energy diminishes, and that the diminution in assimilation of carbon dioxide takes place more rapidly with tolerant species than with those intolerant to shade.

Temperature and toxic action. C. BROOKS (*Bot. Gaz.*, 42 (1906), No. 5, pp. 359-375, *figs.* 33).—A report is given of experiments with a number of species of fungi to determine the modifying effect of temperature on the toxic properties of certain chemicals as shown by the effect of these substances on germination and growth. The chemicals tested were nitric acid, sulphuric acid, and a solution of copper sulphate, and the fungi employed were *Botrytis vulgaris*, *Monilia fructigena*, *Sterigmatocystis nigra*, *Mucor mucedo*, and *Penicillium glaucum*. The first two of these fungi are usually considered parasitic and have a relatively low optimum temperature, while the last three are saprophytes and grow well at temperatures considerably above the optimum for the first two.

It was found that in most cases the deleterious action of the toxic agent increased rapidly with the rise in temperature, although there were marked differences in the various fungi noted. There was a decided drop in the germination curves for *Botrytis* and *Monilia* between 5° and 10°. With *Penicillium* the fall came either between 10° and 15° or between 15° and 20°, while with *Mucor* and *Sterigmatocystis* the downward curves began at 15° or 20°. There was also found a remarkable agreement in the minimum temperature for the germination of a particular fungus under certain conditions and the location of the fall in the germination curve. In all cases the injurious effects were least at the optimum temperature for the germination of the fungus, as shown from check cultures to determine the rate of germination and development.

Taking the total growth as a standard, the injurious effects of the toxic agents decreased with the rise of temperature. This decrease is considered as the result of approaching the optimum for the fungus rather than a mere temperature effect, and the effects produced by the three chemicals were widely different. The injury resulting from the copper sulphate solutions was not as great, comparatively, at 15° as at 20°, while this was true of neither of the acids. Sulphuric acid checked growth at the lower temperatures, but in no case served as a strong stimulating agent. Nitric acid gave similar injurious effects, but at the higher temperatures served as a remarkable stimulus.

Investigations on the effect of soil sterilization on the development of plants. C. SCHULZE (*Landw. Vers. Stat.*, 65 (1906), No. 1-2, pp. 137-147, *pls.* 4).—In connection with previous studies (*E. S. R.*, 13, p. 841) some effects of soil sterilization on the growth of plants were observed, and the author has since carried on experiments to determine the relation between soil sterilization and development of plants.

Pot experiments with field, meadow, and garden soils were made, the plants used being oats, mustard, peas, buckwheat, and grasses. To each pot a nitrogen-free chemical fertilizer was added, which contained phosphoric acid, dibasic calcium phosphate, dibasic potassium phosphate, and magnesium sulphate. One pot of each series was untreated, one sterilized for an hour at

125° C. before fertilizing with the above-described mixture, a third was sterilized at 125° C. after adding the fertilizer, and a fourth was sterilized at 100° C. for 18 hours.

During sterilization there was found to be a formation of more or less injurious decomposition products and also a release of otherwise nonavailable nitrogen. The decomposition products acted upon the different species of plants according to their sensitiveness, and the addition of lime counteracted their injurious effects. In general, sterilization seemed to retard growth for a time, but later the plants became more vigorous in the sterilized pots, often exceeding in total growth those in the untreated pots. In every case the proportion of nitrogen to total plant production was increased in the sterilized pots. Except in those pots in which mustard and peas were grown in sterilized meadow soil, there was an increase in the total plant product, which was attributed to sterilization.

Studies on the lignin and cellulose of wood, P. SPAULDING (*Mo. Bot. Gard. Ann. Rpt., 17 (1906), pp. 41-58, pls. 2*).—A previous author has shown by microchemical methods that cellulose occurs as a distinct lining layer in the walls of wood fibers of perfectly healthy trees, and he claims that a gelatinous thickening layer which reacts to the various color tests for cellulose occurs very commonly in the fiber walls of the xylem as a normal condition in a great number of healthy trees, in all localities and situations. The presence of this unligified layer in the wood fibers he thinks probably represents a stage of arrested development and is not to be attributed to the action of fungi. Furthermore, he claims that delignification can not be attributed to an enzyme secreted by fungi.

These statements the author has investigated to determine the prevalence of cellulose in the trees of America, to test the methods of the previous author's investigations, and to determine to some extent the action of fungi on wood. Two sets of experiments were carried on. The first, which is of a preliminary nature, included but a few species of wood, while in the second about 40 of the more common timber trees were tested.

The tests for cellulose showed that it was fairly abundant in a number of species but in others occurred only in very small quantities or could not be detected at all. In species of *Populus* and *Salix* it was found to form a thick distinct inner layer of the fiber wall which seemed to be somewhat loosely attached to the secondary lignified one. Cellulose was never found in the cells of the oldest wood of the annual rings, but was always situated in the more open early wood.

In testing the methods of the previous investigator it was found that none of the woods were delignified by boiling in the time stated. Apparently the woods used in these experiments were more thoroughly lignified or else their lignin was held more firmly in combination.

The author thinks there is evidence to show the incorrectness of the claim that cellulose is due to arrested development or is present in the form of reserve material. In his studies he finds corroborative evidence of the delignification by means of fungi.

In conclusion, the author states that there can be no doubt that enzymes or some substance exhibiting the characteristics of enzymes have been proved to exist in some of the fungi and indeed in some of the wood-rotting ones. The disappearance of starch in the early stages of attack of some wood-rotting fungi seems to be generally attributed to the secretion of diastase by the fungi, and there appears to be no reason why the disappearance of lignin from the fiber walls, leaving cellulose in the last stages of decay, should be attributed to any cause other than the secretion of a delignifying enzyme.

Cyanogenesis in plants, J. W. LEATHER (*Agr. Jour. India*, 1 (1906), No. 3, pp. 220-225).—After briefly noting the occurrence and distribution of cyanogenetic glucosids in a number of species of plants, the author describes his investigations with 3 species of plants of economic importance.

Analyses are reported of samples of sorghum that were taken as a part of a lot that had been held responsible for poisoning a number of cattle. The fodder when received was partially air-dried and found to yield 1.28 grains prussic acid per pound of green fodder. The crop had been grown under irrigation and was in flower when cut. Other investigations showed a wide variation in the amount of prussic acid, depending apparently upon the variety and the stage of maturity, the content decreasing as maturity was approached. In a sample of sorghum that gave 0.17 grain prussic acid per pound in the air-dried material it was found upon analysis that the leaves contained 2.5 grains, the stalks 1.1 grains, and the flowers 0.25 grain. Sun drying seemed to have no effect on the glucosid.

Experiments with cassava showed that no variety contained prussic acid as such, but all contained a cyanogenetic glucosid, and associated with it was an enzym capable of splitting up the glucosid with the formation of prussic acid. The common classification of bitter and sweet cassava is based upon the amount of glucosid present.

The third plant investigated was flax, the feeding of which was held responsible for the death of more than 50 head of cattle. Specimens of the suspected forage upon analysis yielded 1.4 grains prussic acid per pound of the plant.

In addition to these plants the author reports having obtained prussic acid from beans (*Phaseolus lunatus*) and *Dolichos lablab* by simply allowing the crushed seeds to remain in cold water for a few hours. In the case of seeds of this kind their poisonous properties may be destroyed by boiling them in water.

Cyanogenic glucosids of plants and the utilization of reserve nitrogen, M. SOAVE (*Staz. Sper. Agr. Ital.*, 39 (1906), No. 5, pp. 428-437).—Studies are reported of the germination of the seed of the Japanese medlar (*Mespilus japonica*), in which attempts were made to ascertain the amount of free hydrocyanic acid and the rôle of glucosids occurring in the seed.

It was found that hydrocyanic acid was not present in the seeds of the Japanese medlar, or in such minute quantities as to be shown only by the most delicate tests under favorable conditions. Amygdalin was present, however, often to the extent of 6.89 per cent of the total nitrogen of the seed. With the germination of the seed free hydrocyanic acid appeared, and at some stages of the development was found to amount to as much as 1.93 per cent of the total nitrogen. At the same time the amygdalin and other glucosids increased to 7.22 per cent of the total nitrogen. The nitrogen in the hydrocyanic acid and in the amygdalin was found to amount to as much as 9.15 per cent of the total nitrogen, indicating that the remaining nitrogen in part at least had assumed a glucosidal form. This the author has shown takes place in sweet and bitter almonds, and he believes it will be found true also in experiments with seeds containing cyanogenic glucosids other than amygdalin.

Hydrocyanic acid, which is a widely distributed principle in plants, appears to be the first nitrogenous compound formed by plants and serves as the beginning of the proteid substances elaborated later.

The occurrence of prussic acid and its derivatives in plants, T. A. HENRY (*Sci. Prog. Twentieth Cent.*, 1 (1906), No. 1, pp. 39-50).—A summary is given of the present information relative to the occurrence of prussic acid in plants, the author stating that it has been found in over 100 species of plants representing 22 different orders. The occurrence of prussic acid in plants is in the form of cyanogenetic glucosids, a number of which are described. Associated

with the glucosids are enzymes which act upon the glucosids, liberating prussic acid.

Attention is called to the fact that little is known regarding the method by which prussic acid is produced by plants, although it has been suggested that it is formed by the reduction of nitrates by formaldehyde. The need of further investigations on this subject is pointed out.

A study on leguminous tubercles, J. ŠTEFAN (*Centbl. Bakl. [etc.], 2. Abt., 16 (1906), No. 4-6, pp. 131-149, pls. 2, figs. 2*).—Summarizing his investigations, the author states that the micro-organisms causing root tubercles on leguminous plants live for a time at the expense of the host plant, after which they become degenerate pathological forms. This degeneration is said to be due to the accumulation of injurious substances secreted by the organisms, and extends to the cells of the host plant, ultimately involving the entire tubercle. The transfer of the assimilable nitrogen from the organisms to the host plants follows the ordinary physical laws of osmosis. On the whole the host plant gains by the symbiosis as it receives all the albuminoid substances produced by the micro-organisms and uses them in building up its tissues.

The tubercles which appear in the axils of small rootlets branching from the larger ones really have their origin from the larger rootlets. In some perennial leguminous plants round degenerate tubercles are often found. The author's investigations indicate that in some plants, such as *Galega*, the tubercles serve as true storage organs.

The infection strands of *Phaseolus* were found to not retain their vitality very long, but they are usually as abundant as in the majority of legumes. In the clovers they are especially persistent. In nearly all kinds of infection strands there are to be found numerous sudden swellings which contain the so-called bacteroids. These bacteroids are involution forms which while young are thin-walled and capable of rapid division, but when older become swollen and finally degenerate. The bacteroids seem to be able to break through the infection strands at any point.

In considering the classification of *Bacillus radicolica*, the author thinks it should be placed near the Myxobacteriaceae.

The influence of certain oligodynamic actions on the development and activity of *Bacterium radicolica*, R. PEROTTI (*Separate from Ann. Bot. [Rome], 5 (1906), No. 1, pp. 87-92*).—A series of pot experiments with beans, alfalfa, and red clover was conducted in which, in addition to equal amounts of fertilizing constituents, various amounts of a number of mineral compounds were added. Solutions varying from 1 part in 50,000 to 1 part in 2,500 of the sulphates of potassium, chromium, manganese, iron, cobalt, nickel, and copper, and of the chlorids of barium and mercury were added to the cultures and the effects on growth noted. All the cultures showed a stimulation due to the oligodynamic action of the solutions. In general, there was an increase in growth, dry weight, number and weight of tubercles, etc., corresponding to the increase in the atomic weight of the mineral up to a certain point, after which there was a falling off in a corresponding ratio.

FIELD CROPS.

Guide to plant culture, M. FISCHER (*Leitfaden der Pflanzenbaulehre.---Stuttgart: E. Ulmer, 1906, pp. 231, figs. 113*).—This book is intended for the practical farmer and for use in agricultural schools. It is divided into 3 parts, the first treating of plant culture in general and including plant nutrition, soil, and climate; the second part being devoted to special plant culture, with discussions on the growth of cereals, leguminous crops, forage plants, hoed crops, and industrial crops; and the third part discussing plant breeding in its general

aspect as well as with reference to breeding particular crops. A bibliography is presented.

Report of school of agriculture farm, 1905, W. CARTWRIGHT (*Yearbook Khediv. Agr. Soc. Cairo, 1905, pp. 245-254, chart 1*).—In an outline of the general work conducted at the farm during the year a fertilizer experiment with corn is described. The crop was grown after barley and after berseem. Nitrate of soda was applied at the rate of 104 kg. and ammonium sulphate at the rate of 80 kg. per feddan (1.08 acres). The quantities of nitrogen furnished by these applications were equal to the amount applied in a 10-ton dressing of manure. The gain from the use of nitrate and manure was insufficient to pay for the expense incurred, but the ammonium sulphate gave a profit which is considered due to its having been more fully utilized than the nitrate. The increase produced by the sulphate after berseem was far less than after barley, which is taken to indicate that the optimum application on the berseem field had been passed.

Alfalfa as a forage crop for Pennsylvania, G. C. WATSON (*Pennsylvania Sta. Bul. 79, pp. 12*).—General notes on the culture of alfalfa in Pennsylvania, together with reports of experiments conducted on the station farm and in Lancaster County of the State.

It was found in these experiments that alfalfa thrived in a compact, gravelly soil of good drainage quite as well as in a loose loam. In fertilizer tests the crop made the best growth where a heavy application of phosphoric acid and potash had been made. The use of 5 tons of barnyard manure per acre gave better results than the phosphoric acid and potash contained in 500 lbs. of a good brand of commercial fertilizer. Turkestan alfalfa did not give as good results as common alfalfa.

It was also found that fall-sown alfalfa on dry land withstands the severe winters of this climate perfectly and better than the common red clover. In several instances, however, the alfalfa withstood the first winter, but was completely winter killed during the second. The larger growth seemed to give no assurance of success on wet soil. It was observed that where the plants made a strong and vigorous start the roots were provided with nodules, while where plants were weak and slow in starting, only a few of the plants were so provided. Lime was in no case applied to advantage.

The A B C of corn culture, P. G. HOLDEN (*Springfield, O.: Simmons Pub. Co., 1906, pp. 92, figs. 84*).—This is a popular treatise on corn culture, discussing briefly soil preparation, cultivation, preparation of seed corn, combating corn pests, harvesting and storing seed, selection and judging of corn, and the importance of the crop. Descriptions are also given of a number of standard varieties.

Score card for dent corn (Ohio Sta. Bul. 61, pp. 4).—The score card presented has been adopted as the official score card of the Ohio Experiment Station and the department of agronomy of the State University. The different points are briefly explained.

Cotton, its production, consumption, and economic importance, R. PUPIN (*Le Coton, sa Production, sa Consommation, son Rôle Économique. Paris: Felix Alcan, 1906, pp. 84*).—The history of cotton is briefly reviewed, and its culture, commerce, and consumption, together with its influence as an economic factor discussed, and statistics bearing on different phases of production and trade are presented. The processes of spinning cotton and manufacturing and dyeing cotton fabrics are also described.

The selection of cotton seed, G. P. FOADEN (*Yearbook Khediv. Agr. Soc. Cairo, 1905, pp. 119-141, pl. 1, figs. 3*).—The necessity for the selection of cotton seed is discussed, the method used in Egypt described, and plans for a more systematic selection outlined.

It is stated that small cultivators use seed of common quality, regardless of origin and purity, and that to overcome this difficulty the Khedivial Agricultural Society, in connection with the agricultural bank, distributes annually the best seed obtainable at cost price, the value of which is collected at the end of the following cotton season. This system does nothing to actually improve the seed and for this reason the country is in urgent need of a more effective method of selection and distribution. A description of cotton seed selection, as given in the Yearbook of this Department for 1902, is reproduced. It is pointed out that a variety of cotton known as Hindi is found mixed with the improved varieties, especially Adifi, and that the elimination of this sort from the better kinds is one of the principal problems connected with seed selection.

Experiments with oats, J. F. DUGGAR (*Alabama College Sta. Bul. 137, pp. 59-94, figs. 8*).—This bulletin summarizes the experiments with oats conducted by the station over a period of 10 years.

In the tests of varieties the yields of Red Rust Proof, Appler, and Culberson, when sown in the fall, were practically equal. When sown after Christmas, Burt or May oats averaged 7 per cent less grain than Red Rust Proof. Turf, or Gray winter oats, sown in November produced only 59 per cent as much grain as Red Rust Proof sown at the same time. The order of ripening of the principal varieties sown in the fall was Burt, Red Rust Proof, and Turf. Red Rust Proof and its related varieties or strains, Appler and Culberson, are regarded as the best general-purpose varieties for that region. Burt oats was found chiefly valuable for its earliness, but it was apparently not as hardy as some of the other sorts.

The experiments conducted to determine methods for the reduction or prevention of winterkilling indicate that sowing in deep drills in October, growing a hardy variety, and using the land roller after the plants have been heaved and their roots exposed, are the most effective means. As compared with broadcasting, oats drilled in deep furrows about 2 ft. apart yielded 3.2 bu. per acre more when the deep furrows were only partly filled and 2.3 bu. more when the furrows were almost completely filled.

In general, fall sowing gave much better results than spring sowing. In 7 experiments made in 7 different years, Red Rust Proof sown in November gave an average of 11.3 bu. per acre more than when sown in February. From the results secured, it is advised to sow the seed in the fall in October and in the spring, during the first few days of February.

The results of the fertilizer tests show that nitrogenous fertilizers were more profitable than phosphate or potash on the sandy and loamy soils of the station, but they also indicate that on such soils the application of 100 lbs. of acid phosphate at the time of sowing may be recommended. Nitrogen in the form of nitrate of soda was more effective than in any other forms, and was also somewhat more effective in the form of cotton-seed meal than of cotton seed. It is advised to apply cotton seed or cotton-seed meal at the time of sowing and nitrate of soda as a top dressing in March after growth begins. Barnyard manure greatly increased the yield of oats and exerted some effect on the next crop. In one experiment 43.1 lbs. of nitrate of soda and 103 lbs. of acid phosphate were required to produce the same increase as 1 ton of fine, fresh, unbleached horse manure. In 13 experiments with nitrate of soda the yield and total profit increased with the quantity applied up to 200 lbs. per acre, but the cost of nitrate of soda required to produce one additional bushel of oats was 14.5 cts. from the use of 63 lbs. per acre, 17.7 cts. from the use of 100 lbs., and 21.1 cts. from the use of 200 lbs. Cowpeas, velvet beans, peanuts, or soy beans, whether the entire growth was plowed under the fertilizer or only the stubble, gave an increase in the succeeding oat crop of from 6.2 to 33.6 bu. per acre.

HORTICULTURE.

The relation of winter apples to hardiness of trees, W. T. MACOUN (*Canad. Hort.*, 29 (1906), No. 12, pp. 291, 292, fig. 1).—As the result of 17 years' experimental tests with over 3,000 species and varieties of trees and shrubs other than cultivated fruits, the author states that a tree or shrub which will withstand a winter at Ottawa must be one that ripens its wood early. During the period of experimenting no apparent increase in hardiness has taken place in any of the individual specimens. "Plants which killed to the ground 17 years ago, kill to the ground still. Those which killed to the snow line, kill to the snow line still. Those which were killed back one-half or merely a few inches at the tip, do so still. Sometimes a tree will remain hardy for several years and then kill back near to the ground. It is possible that they are getting hardier very gradually, but if so this increasing hardiness is imperceptible so far." It has been noticed that following a season of strong growth in the trees winterkilling is more severe than when the growth is medium. Individual specimens of a species have been found hardier than others. This has been the case especially with *Catalpa bignonioides*.

Out of 700 named varieties of apples which have been tested at the station, the hardiest have come from the Northeastern and Northwestern States and Canada. The hardy varieties from Great Britain, France, and Germany are few as compared with those from the colder parts of Russia. Following the test winter of 1903-4, 164 varieties of apples were winterkilled. Of this number 130 were early winter and winter varieties and only 34 summer and autumn varieties. Summer and early autumn varieties stop growth and ripen up their wood sooner in the season than the late-growing winter apples, and on this account are more able to withstand the severe winters. Fruit trees which originated in sections where the growing season is long usually winterkilled when grown in the short seasons of the north.

The larger part of the apples of merit which have been originated recently from seedlings in Canada are summer and autumn kinds. In order to secure new varieties which will mature in short seasons it is considered of vital importance that the ancestors of the seedlings be short season varieties. It is believed "that the basis for the production of the desired winter apple for the north should be a variety or varieties which have withstood test winters in the north and are also the latest keepers of such varieties."

A list is given of the varieties of apples which originated in the north and which stood the test winter of 1903-4. The list includes Canada Baldwin, Winter Rose, Calmet, Baxter, La Victoire, Stone, Scott Winter, and Milwaukee. From these varieties and other hardy seedlings growing at the station it is believed the prospect is bright for the origination of a hardy, long-keeping winter variety of good color and best dessert quality for the north.

Further experiments in the cool storage of fruit, G. QUINN (*Jour. Dept. Agr. So. Austl.*, 10 (1906), No. 2-3, pp. 75-78).—Accounts are given in continuation of those previously noted (*E. S. R.*, 17, p. 768) of storing plums, apples, and pears in cold storage for different lengths of time.

Burbank and Wickson plums were gathered when nearly matured, carefully wrapped in tissue paper and embedded in softwood wool in shallow trays, and then placed in cool storage for 8 weeks. The results were very unsatisfactory. The Burbank plums when withdrawn from storage, though not rotten, were shrunken in spots, the tissue being hard, brown, and tasteless, while the intervening spaces were practically normal in appearance. The Wickson fruits were practically flavorless and exhibited a brown discoloration around the pits. After a week

the flavor was very disagreeable, though not due to the ordinary processes of decay.

A large number of varieties of apples were successfully kept for 19 weeks in cold storage in a temperature ranging from 33 to 36° F. A number of pears kept for the same length of time gave less satisfactory results. It is believed, however, that with proper care in handling the fruit both apples and pears can be kept sufficiently well for shipment to English markets.

Fertilizing forced strawberries, VON BREHMER (*Gartenwelt*, 11 (1906), No. 7, pp. 78, 79).—An account is given of forcing strawberries in pots filled with the same kind of soil but differently fertilized. Chemical fertilizers were used and applied to the plants once a week in water solutions. There were 26 plants in 8-in. pots in each series.

The first ripe fruit in the control pots was secured May 28 and the total yield up to June 12 was 315 gm. When the plants were fertilized with a mixture of phosphoric acid and nitrate of potash the first ripe fruits were secured May 23 and the total yield was 2,050 gm. When to these fertilizers nitrate of lime was added the first ripe fruit was secured May 16 and the total yield was 3,950 gm. It is thus seen that by the use of a complete fertilizer plus nitrate of lime the yield was more than 10 times greater than where no fertilizer was used and the fruit ripened nearly 2 weeks earlier in the season.

Date varieties and date culture in Tunis, T. H. KEARNEY (*U. S. Dept. Agr., Bur. Plant Indus. Bul.* 92, pp. 112, pls. 10, figs. 52).—Descriptions are given of 105 varieties of dates grown in Tunis, with a descriptive key to the characters of the fruit and an account of the characteristics of the principal date regions in Tunis and of the culture of the date palm. The number of varieties described in the bulletin is believed to be only about one-fourth of those in actual cultivation there but includes all of the more important varieties. The author personally visited the different regions described and succeeded in securing about 700 off-shoots representing 56 varieties, which were sent to the United States for trial. The descriptive key which has been worked out the author believes will become useful in identifying the Tunisian varieties.

Resistant vineyards. Grafting, planting, cultivation, F. T. BIOLETTI (*California Sta. Bul.* 180, pp. 87-114, figs. 29).—An extensive account is given of the details of grafting, planting, and nursery management for the establishment of resistant vineyards in California. Much of the matter contained has been given in earlier publications of the station (*E. S. R.*, 12, p. 241).

Manurial experiments with cacao in Dominica (*West Indian Bul.*, 7 (1906), No. 3, pp. 201-212).—A summary is given of the fertilizer experiments carried on at the Dominica Botanic Station since 1900, some of the results of which have been previously noted (*E. S. R.*, 17, p. 76). In addition the results secured on experimental plats in 7 country districts are noted.

At the botanic station the use of basic phosphate and potash without nitrogenous manure has not proved beneficial, but when dried blood has been added there has been a striking increase in the yield per acre. A complete fertilizer therefore, is recommended. Even the application of dried blood alone has shown very beneficial results, there being a gain of 308 lbs. of wet cacao, or 4.4 lbs. per tree over the no-manure plat.

The most interesting results have been obtained on the plat mulched with grass and leaves, the sweepings of the lawns at the botanic station. At first the yields on this plat while in excess of those on the no-manure plat were considerably less than on the fertilized plats. During the past 3 years, however, the yields from this plat have greatly exceeded those of any other plat in the experiment. In 1905 the yield was 38.91 lbs. of wet cacao per tree against 22 lbs. from the no-manure plat, or a gain of 77 per cent. It is believed the plat has

been permanently improved by the application of the mulch, as the soil is more moist and dark in color and the trees have a better surface root development. The experiment is believed to show that a large increase in the yield of cacao can be obtained without the use of artificial manures and as mulching material is abundant it appears wasteful and unnecessary to purchase other manures. These results are believed to answer the question as to the best way to improve cacao cultivation in Dominica.

The results secured on the various fertilizer plats in the country districts indicate the phosphatic manures are quite generally beneficial.

Report of inspector of cocoanut plantations for the year 1905, L. C. BROWN (*Agr. Bul. Straits and Fed. Malay States, 8 (1906), No. 8, pp. 265-269*).—The area under cocoanuts in the Federated Malay States in the year 1905 was estimated at 100,000 acres, on over half of which the trees were in bearing. An account is given of the acreage in each of the different districts and of the prevalent insects and diseases affecting the crop, with notes on cultivation, marketing, copra, oil production, etc.

FORESTRY.

Indian trees, D. BRANDIS (*London: Archibald Constable & Co., 1906, pp. XXXIV+767, figs. 201*).—This book is a systematic account of the trees, shrubs, woody climbers, bamboos, and palms indigenous or commonly cultivated in the British Indian Empire. It is designed for the use of foresters and others who wish to make themselves acquainted with Indian trees. The arrangement is botanical, and descriptions are given of over 4,400 species, 201 of which are illustrated. The author states that the book is not intended for botanists, but rather for foresters and practical men, and on this account species of doubtful value or which are imperfectly known have, as a rule, been omitted.

Forests as accumulators of nitrogen, E. HENRY (*Bul. Soc. Forest. Franche-Comté et Belfort, 8 (1906), No. 7, pp. 681-695*).—The author discusses the increase in nitrogen content of soils on which forests are grown and cites the recent work of M. Süchting and L. Montemartini, which is confirmatory of the author's experiments in showing that the dead leaves of forests are capable of fixing a considerable amount of free atmospheric nitrogen (*E. S. R., 16, p. 444*).

Fertilizer experiments in forest nurseries, SCHALK (*Forstw. Centbl., n. ser., 28 (1906), No. 11, pp. 569-579, pls. 3, fig. 1*).—The results are given of a number of experiments in fertilizing forest nursery trees. The experiments were carried out on rather swampy land 1,500 to 2,000 ft. above sea level and very subject to late spring frosts. The soil in the nursery was poor, as shown by the fact that spruce trees after 4 years stood hardly 15 cm. high.

When the soil was fertilized with 6 kg. Thomas slag, 3 kg. kainit, 1.5 kg. nitrate of soda per acre, the trees attained a height of 25 to 30 cm. at the end of 2 years. In a number of further experiments it was shown that fertilizing with composted lime, while giving good results, was surpassed in usefulness by complete fertilizers. Potash fertilizer was in no wise unnecessary, for it was only when this fertilizer was used that the full effect of phosphatic and nitrogenous fertilizers were obtained. This was true even on clay soils supposed to be well supplied with potash. Kainit appeared to be somewhat more effective early in the season than other forms of potash.

The use of lime in addition to Thomas slag increased the effect of the latter in a visible manner, but was not entirely necessary. Uninoculated lupines were of no benefit in preparing the land for nursery stock, but when inoculated they made a full development and produced practically as good results as other

forms of nitrogen. In all these experiments nitrate of soda, when used in combination with Thomas slag and kainit, was very effective.

Farm wind-breaks and shelter-belts, S. B. GREEN (*St. Paul, Minn.: Webb Pub. Co., 1906, pp. 69, figs. 26*).—The uses of wind-breaks and shelter-belts for the protection of farm buildings and stock, especially in the prairie States, are discussed and directions given for propagating and planting trees suitable for these purposes. Chapters are also given on landscape gardening, nursery practices, and tree protection.

Notes on rubber-producing plants, W. HARRIS (*Bul. Dept. Agr. [Jamaica], 4 (1906), No. 11, pp. 241-282*).—A large amount of information on the various rubber-producing plants has here been brought together in pamphlet form for the use of intending rubber planters in Jamaica. It is believed that the Lagos silk rubber (*Funtumia elastica*) will prove to be one of the best, if not the best, for many Jamaica districts.

DISEASES OF PLANTS.

Notes on plant pathology, G. DELACROIX (*Bul. Mens. Off. Renseign. Agr. [Paris], 5 (1906), No. 11, pp. 1349-1363*).—Notes are given on a bacterial canker of poplar trees, a bacterial disease of potatoes, a disease of Carolina poplar, and a bacterial disease of onions.

The bacterial disease of poplar resembles in many respects the canker produced by *Nectria ditissima*, but a thorough study of the disease and its cause shows that it is due to a micrococcus, for which the author proposes the name *Micrococcus populi* n. sp. The organism has been isolated and studied. In the author's experiments he has failed to secure infection except where inoculations were made through punctures or injuries caused by hail or some insect. In this way he has been able to cause the disease in many instances, but only where cultures were used in which the organism had been grown in a medium containing an extract of the poplar bark. Where the disease is prevalent the author recommends the burning of infested trees, or, if the attack is a slight one, cutting out and burning the young branches.

The bacterial disease of potatoes described is that due to *Bacillus phytophthorus*, a disease which is known by the names black shank, stem rot, etc., in various parts of Europe. The author calls attention to the differences between the disease caused by this bacterium and that due to *Bacillus solanincola*. He reports that the bacteria are almost always accompanied by the mycelium of a species of *Fusarium*, an observation that seems to have been overlooked by other investigators.

The disease of Carolina poplar described is due to the fungus *Dothichiza populca*, and a study is given of the parasite, its method of attack, etc. The author recommends for its prevention the destruction of all dead branches, etc., which contain the fruiting bodies of the fungus, and spraying with Bordeaux mixture or other fungicide.

The bacterial disease of onions briefly described is said to be similar to, if not identical with, that mentioned by a number of authors, among them Stewart (*E. S. R., 12, p. 56*). For the prevention of this disease the rotation of crops and the addition of superphosphate of lime to the soil are recommended.

Fungoid pests of cultivated plants, M. C. COOKE (*London: Spottiswoode & Co., Ltd., 1906, pp. XV + 278, pls. 24, figs. 23*).—Brief popular and technical descriptions are given of a large number of fungi which are known to attack cultivated plants, together with suggestions for combating them. The material is grouped under the following heads: Pests of the flower garden, vegetable

garden, fruit garden and orchard, vinery and conservatory, ornamental shrubbery, forest trees, and field crops. These accounts are reprinted from the Journal of the Royal Horticultural Society (E. S. R., 14, p. 1090; 15, pp. 269, 689; 17, p. 158).

Cereal smuts and their propagation, T. JOHNSON (*Sci. Prog. Twentieth Cent.*, 1 (1906), No. 1, pp. 137-149).—A summary of information is given relating to the more important grain smuts and notes are given regarding their propagation. The methods of infection by the different smuts are described at some length, and the use of fungicides for preventing smuts is commented upon, the remarks being based upon the methods of infection.

For the oat smut seed treatment is very efficient, as the infection takes place in the seedling stage of the plant, but with the wheat smut (*Ustilago tritici*) and the barley smut (*U. hordei*) the author claims that treatment with fungicides is of little avail, as the infection takes place during the flowering stages of the plants. For the prevention of smut of maize fungicides are valuable, as the infection is local and the presence of the fungicide on the plant prevents the germination of the adhering spores.

Oat smut and its prevention, O. APPEL and G. GASSNER (*Deut. Landw. Presse*, 33 (1906), No. 89, pp. 704, 705, fig. 1).—A description is given of the smut of oats due to *Ustilago arcaea*, and for its prevention the author describes the method of seed treatment with formaldehyde and the hot-water method. An account is given of a patented apparatus which is said to simplify the methods of hot-water treatment. Brief notes are given on the form of smut due to *Ustilago levis*, and for its prevention the methods described for the other species are recommended.

The physiology of the parasite of sore shin of cotton, W. L. BALLS (*Year-book Khediv. Agr. Soc. Cairo, 1905, pp. 171-195, pls. 2*).—A study is reported of the sterile fungus described by Atkinson in Alabama College Station Bulletin 41 (E. S. R., 4, p. 832), which the author has found present and causing considerable injury in the cotton fields of Egypt. The characteristic appearance of the disease and its economic importance are described, after which notes are given on the fungus, its appearance in cultures, its temperature relations, parasitism, etc.

The author states that the Egyptian sore shin is identical with the disease known in this country, and the physiology of the parasite is relatively simple. Further studies are to be carried on as to the morphology of the organism, soil conditions, causes of irregular distribution, and means for prevention.

"Black root" disease of cotton, R. I. SMITH and A. C. LEWIS (*Ga. Bd. Ent. Bul.* 22, pp. 237-275, figs. 12).—An account is given of the black root or wilt of cotton due to *Necocosmospora vasinfecta*, which is becoming very troublesome in parts of Georgia.

After describing the cause of the disease, distribution, losses, etc., the authors consider means for reducing the loss. It is recommended that diseased plants should be dug up and burned, or where large areas of cotton are affected the stalks should be plowed out, raked, and burned in the fall as soon as the cotton is gathered. In this way the cotton roots and stems containing the fungus may be destroyed and the possibilities of spread will be lessened.

Experiments with Bordeaux mixture, copper carbonate, sulphur, carbolic acid, formalin, and applications of lime and kainit have failed to control or materially lessen the disease.

Variety tests have shown that certain varieties are somewhat naturally resistant to the black root or wilt, and that the resistant quality of some of these may be strengthened by careful selection of seed from the best plants.

Cotton growers are urged to follow out this selection, as it seems to be one of the most promising methods of combating the disease. The rotation of crops is also recommended.

The relation of nematodes to the disease is pointed out, the authors claiming that the presence of nematodes aids in its development.

A new alfalfa disease, W. PADDOCK (*Colorado Sta. Press Bul.* 28, pp. 2).—A brief account is given of a disease of alfalfa that has caused considerable damage in a number of localities in Colorado. In June, 1906, the author had the opportunity of inspecting infected fields during the growing season. The cause of the injury was apparent, as shown by the occurrence of numerous blackened stems from which a thick juice was oozing, plainly indicating that the plants were suffering from a bacterial blight. Subsequent examination showed that this was the probable cause of the disease.

The first evidence of disease to be noticed is a short, weak, light-colored growth of the first crop, the stems seldom averaging more than a foot in height at the time the first cutting is made. A close examination shows that the majority of these stems are discolored and are very brittle. The disease apparently does not kill many plants the first year, but in course of time so many plants die that the fields become useless.

Almost nothing is known of the blight as yet, and the horticultural section of the station solicits correspondence regarding its occurrence.

Potato leaf curl (*Roy. Bot. Gard. Kew, Bul. Misc. Inform.*, 1906, No. 7, pp. 242-245).—After describing the leaf curl of potatoes, due to *Macrosporium solani*, attention is called to the fact that the fungus is perpetuated from year to year by mycelium in the tubers. When infested tubers are planted the mycelium grows along with the stem and enters the leaves, and also passes down into the young tubers. When only slightly infested with mycelium the further development in the tissues of the potato plant will depend on the weather conditions. It may do little harm beyond infecting the new tubers, or, if conditions are favorable, develop into an epidemic form and destroy the infested portions of the potato plant.

The fungus mycelium does not destroy the starch of the tuber, but lives only on the proteid substances, and it is practically impossible to tell by superficial methods whether a tuber is killed or not.

Owing to the fact that the conidia of the fungus are only produced on dead or dying plants, the epidemic is not increased by healthy plants having their foliage infested by the conidia, as in the potato blight. Young shoots may be infected late in the season, but the infection remains local and does not extend to the tubers. According to the author, the infection can only take place through the tuber, and this can be brought about either by planting diseased tubers or from conidia present in the soil.

A series of experiments has shown that the minimum temperature for germination of conidia is 47° F., with a maximum of 78° and an optimum of 64°. It is claimed that the resting spores of the fungus have germinated after having been kept in the laboratory for 6 months in a perfectly dry condition, and it is quite probable that they remain in the soil from one season to another without losing their power of germination.

Comparative studies have been made with the leaf curl of tomato (*Macrosporium tomato*), and inoculation experiments have proved that the two fungi are identical, the conidia from the tomato infecting potato plants and vice versa.

As practical means for combating these diseases, the author recommends planting potatoes from districts free from disease. The potatoes should not

occupy ground for at least 3 years where a diseased crop has been produced. All diseased stems should be collected and burned or deeply buried, and this should apply also to diseased tomato stems and fruit, otherwise the potato crop may be infested.

Soil treatment of tobacco plant beds, A. D. SELBY (*Ohio Sta. Circ.* 59, pp. 3, fig. 1).—In the spring of 1906 the author carried on some experiments to test the effect of solutions of formalin as a drench on old tobacco beds to destroy the bed rot (*Rhizoctonia* sp.).

The results were doubtful in some cases and favorable in others. In order to overcome some of the disadvantages of spring application fall treatments are recommended. The treatment consists of the application of a solution of formalin of the proportion of 2 lbs. formalin to 50 gal. of water, to be applied to the seed bed at the rate of 1 gal. to each square foot of surface. This treatment should be made before freezing weather begins, and the beds left without disturbance until spring, when they may be prepared for seeding.

A thorough trial of this method is recommended, which it is believed will not only keep down the *Rhizoctonia*, but also the damping-off fungus (*Pythium* sp.) and the black root due to *Thielavia*.

Diseased apples and melons from the Cape of Good Hope, G. MASSEE (*Roy. Bot. Gard. Kew, Bul. Misc. Inform.*, 1906, No. 6, pp. 193-196, pl. 1).—Descriptions are given of diseased apples and melons which were forwarded to the Kew laboratory for examination.

In the case of the apple the disease is indicated by the appearance of minute, scattered, discolored blotches on the skin. After several weeks the blotches increase in size and at the same time become sunken or depressed below the surface. A microscopic examination showed the cells underlying each spot to be dead and collapsed and often crowded with starch grains, whereas the starch had entirely disappeared from healthy cells in the process of ripening.

Neither fungi nor insects were found to play any part in the disease, which is considered to be of a purely physiological nature and caused by irregularities in the ripening of the fruit. It is probable that the injury to the fruit was due to too high temperature during the early period of ripening.

In the case of diseased melons the specimens exhibited small, roundish, pale-brown patches upon the surface of the rind, which on examination were found to be caused by the fungus *Macrosporium sarcinula*. Inoculation experiments showed that the conidia of the fungus was capable of infecting melons. The removal and destruction of diseased melons and thorough spraying with some fungicide on the first indication of the disease are recommended as preventive measures.

Pear rust, H. T. GÜSSOW (*Gard. Chron.*, 3. ser., 40 (1906), No. 1025, p. 134, figs. 2).—A brief account is given of the pear rust fungus, which is the aecidial stage of *Gymnosporangium sabinae*, and the author calls attention to a severe outbreak of the disease in England. The life history of the fungus is described at some length, and the fact that the fungus hibernates on the shoots of various species of Juniper is mentioned.

Spraying with Bordeaux mixture for the protection of the pear leaves is recommended, but the author thinks that this would be impracticable in large orchards and that a simpler remedy would be the destruction of the Juniper bushes, providing this should prove possible.

The development and prevention of the gray rot of grapes, J. M. GUILLON (*Rev. Vit.*, 26 (1906), Nos. 659, pp. 117-124, figs. 3; 660, pp. 149-152; 661, pp. 181-186, figs. 2).—After describing the gray rot of grapes due to *Botrytis cinerea*, the conidial phase of *Sclerotinia fuckeliana*, an account is given of

the development of the conidial phase of the fungus, the methods of infection, and investigations for its control.

The conidia will not germinate at a very low temperature, and they are destroyed at a temperature beyond 35 to 38°. However, the temperature and moisture are frequently such as to produce very rapid growth. The primary infection takes place through the germination of spores in contact with the grapes, and the germ tubes soon penetrate the cuticle of the berry, usually through insect punctures or other wounds. From this primary infection the fungus spreads from berry to berry through contact, and on this account those varieties with very compact clusters suffer the most. The spread of the disease is shown to be very closely associated with the rainfall, rapid development following periods of abundant precipitation.

In experiments for the control of this disease the author made applications at 8 and 15 day intervals, covering a period of 2 or 3 months, of Bordeaux mixture, a mixture composed of nickel sulphate neutralized with lime, Bordeaux mixture to which sugar is added, verdigris solution, and solution of permanganate of potash, and in addition tested the value of powdered lime and plaster and sulphate of alumina. At the end of the season the grapes were gathered and the yields from the rows receiving the different treatments were compared.

It was found that the fungicides containing copper in soluble form, such as those containing sugar, verdigris solution, etc., gave better results than where the ordinary form of Bordeaux mixture was used. The nickel sulphate solution gave results comparable with or somewhat better than the others, but the high cost of the nickel sulphate precludes its use. The powders of lime and alumina gave good results, so far as the gray rot is concerned, but their manifest inferiority in combating mildew is against their recommendation for extensive use. Potassium permanganate for combating this disease proved of little value. For general use the author considers the sulphate of copper to be the best fungicide.

Some diseases of palms, E. J. BUTLER (*Agr. Jour. India*, 1 (1906), No. 4, pp. 299-310, pls. 2).—Accounts are given of diseases of a number of palms which have been under the author's observation. Among them is a disease of betel palms that is due to *Phytophthora* sp., another is a disease of the same tree caused by one of the higher fungi, probably a species of *Fomes*, and a third a disease of the palmyra palm caused by *Pythium* sp.

A new disease of cultivated veronicas (*Gard. Chron.*, 3. ser., 40 (1906), No. 1026, p. 150).—A brief note is given on the occurrence of a fungus on *Veronica speciosa* and its varieties, which are in rather extensive cultivation. The fungus, which is said to be *Septoria croatica*, is met with occasionally during the summer, but it develops rapidly in autumn and winter when the plants are grown under glass. It produces small gray spots on the leaves, and in the course of 2 or 3 weeks the spots become white. Later the leaves fall, so that the plants assume a naked appearance with but few remaining leaves. The fungus has been observed in Argentina, Italy, and Germany. For the prevention of its attack, spraying with ammoniacal copper-soda mixture is recommended.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Revision of the skunks of the genus *Spilogale*, A. H. HOWELL (*U. S. Dept. Agr., Bur. Biol. Survey, North American Fauna* No. 26, pp. 55, pls. 10).—This genus of skunks has in general a southern distribution, reaching, however, into West Virginia, southern Minnesota, and Washington. The genus extends south-

ward into Central America and is represented in this territory, according to the present account, by about 20 species.

Notes are given on the habits and specific distribution of these animals. The food consists largely of insects, mice, and other small animals, as well as some vegetable material. A detailed description is given of each species with notes on its distribution.

The monthly bulletin of the division of zoology, H. A. SURFACE (*Penn. Dept. Agr., Mo. Bul. Dir. Zool., 4* (1906), No. 6, pp. 209-240, pls. 2).—Copies are given of a considerable number of official letters in the regular correspondence of the office of the economic zoologist regarding various insect pests and other matters.

Entomological section, C. W. HOWARD (*Transvaal Agr. Jour., 5* (1906), No. 17, pp. 168-176, pls. 3, fig. 1).—*Bagrada hilaris* has been a serious pest on cabbages and cauliflowers in the Transvaal for several years. It attacks other cultivated and wild members of the mustard family. Since the pest is very fond of wild mustard, it may be trapped on this crop and sprayed with pure kerosene. Fairly good results have also been obtained from the use of resin wash.

Attention is also called to the attack of *Caradrina exigua* on tobacco, cotton, corn, and other plants. This pest feeds also upon pigweed and many other wild plants. A number of natural enemies are known, but if these are insufficient excellent results follow the spraying with Paris green.

An expedition for the study of plant pathology in Kamerun and Togo, 1904-5, W. BUSSE (*Tropenpflanzer, Beihefte, 7* (1906), No. 4-5, pp. 163-262, pls. 4, figs. 8).—During the author's travels in Kamerun and Togo observations were made on the culture, insect pests, and plant diseases of cacao, rubber plant, cotton, cola, and other cultivated plants.

In the control of the fungus diseases of cacao, the author recommends the general use of Bordeaux mixture as giving results equally as satisfactory as those obtained with this fungicide in temperate regions. The author describes various special apparatus which may be suitable for spraying cacao trees.

A number of insects of minor importance are mentioned as attacking rubber trees in Kamerun. These include *Phrystola cocca*, *Glyphodes ocellata*, etc.

The varieties and forms of cotton grown in Togo are described, with notes on the cultural methods used in raising this crop. Many insect pests attack cotton in Togo and some of them are described, with notes on their life history, particular attention being given to *Earias insulana*, a pest which closely resembles our boll worm, *Dysdercus supersticiosus*, etc.

List of publications of the Bureau of Entomology, MABEL COLCORD (*U. S. Dept. Agr., Bur. Ent. Circ. 76*, pp. 21).—This list of publications of the Bureau of Entomology was compiled for the use of librarians and entomologists.

The slender seed-corn ground-beetle, F. M. WEBSTER (*U. S. Dept. Agr., Bur. Ent. Circ. 78*, pp. 6, figs. 2).—*Clirina impressifrons* is described, with notes on its distribution and habits. It attacks seed corn near the germ after the kernels have become softened by the moisture of the soil. In the spring of 1906 an unusual amount of injury was done. Damage is reported from Pennsylvania to Kansas, but in some localities a part of the injury may have been due to *Agonoderus pullipes*. No successful curative or preventive remedy has been devised.

Lita ocellatella on sugar beets, A. GIARD (*Compt. Rend. Acad. Sci. [Paris], 143* (1906), No. 18, pp. 627-630).—Some difference of opinion has existed as to the identity of this insect, which is well known in France as an enemy of sugar beets. The life history of the pest is briefly described and notes are given on its feeding habits.

The potato moth, C. FRENCH (*Jour. Dept. Agr. Victoria*, 4 (1906), No. 10, pp. 577-582, pl. 1).—A description is given of *Phthorimaea operculella* in all its stages. In combating the pest the author suggests the use of lantern traps, lime sprinkled on potatoes in storage, a careful examination of seed potatoes before planting, and the use of gas lime at the rate of 30 bu. per acre on the soil after the potatoes have been dug.

Thrips or black fly, W. W. FROGGATT (*Agr. Gaz. N. S. Wales*, 17 (1906), No. 10, pp. 1005-1011, pl. 1).—The habits and essential features of the life history of thrips are briefly outlined with special notes on some of the more interesting species in New South Wales. These include *Thrips tabaci*, *Heliiothrips hamorrhoidalis*, *Idolothrips spectrum*, etc.

These insects may usually be destroyed by fumigation with tobacco or hydrocyanic-acid gas.

The melon aphid, F. H. CHITTENDEN (*U. S. Dept. Agr., Bur. Ent. Circ.* 80, pp. 16, figs. 6).—The melon aphid (*Aphis gossypii*) is generally distributed throughout the United States but is especially injurious in the Southwest. It attacks a great variety of economic plants belonging to different families. The natural enemies of the pest are ordinarily not sufficient to hold it in control. It may be destroyed by fumigation with carbon bisulphid or by the use of pyrethrum, tobacco fumes, or kerosene emulsion. Treatment with kerosene emulsion has the advantage that it is also destructive to a considerable variety of other insects which attack cultivated plants in conjunction with the melon aphid.

Spraying to control the San José scale, R. I. SMITH (*Ga. Bd. Ent. Bul.* 21, pp. 201-236, figs. 19).—As a result of further experiments with lime-sulphur washes in the control of the San José scale, the author recommends a boiled lime-sulphur wash. Salt does not appear to be necessary or desirable, but the lime used should be a calcium lime rather than a magnesia lime. Self-boiled lime-sulphur washes are often used with good success but are more expensive and not quite so satisfactory as boiled washes. For spraying on a large scale, steam-boiling outfits are most satisfactory. It is recommended that badly infested orchards be sprayed in the fall and in the spring, but where 2 sprayings are impossible the applications should be made in the spring.

Soluble oils as destroyers of San José scale, H. A. GOSSARD (*Ohio Sta. Circ.* 60, pp. 4).—The station has continued its work with proprietary preparations of soluble oils (E. S. R., 17, p. 993) with the result that these materials appear to compare favorably with lime-sulphur wash in effectiveness as remedies for scale insects. In general they may be diluted in water so as to form 5 per cent solutions.

It is suggested, however, that the variable results obtained with soluble oils indicate a variation in composition, and when safety, cost, and efficiency are considered, the author recommends lime sulphur as the best remedy.

Insect pests affecting fruit trees, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope*, 29 (1906), No. 4, pp. 500-511).—The cultivation of crops over large areas offers better opportunity for indefinite multiplication of injurious insects than would be found in a state of nature. The author calls attention to the development of arsenical poisons and to their application in the control of injurious insects. Particular mention is made of the codling moth and of the little help which can be expected from its parasites.

A plague of *Macroductylus mexicanus* in the valley of Mexico, J. R. INDA (*Com. Par. Agr. [Mexico], Circ.* 46, pp. 8, figs. 2).—This pest is a serious enemy of horticulture and attacks a considerable variety of plants. In combating the

insect the author recommends the use of a mechanical mixture of kerosene and water.

Caterpillar plagues, A. L. HERRERA (*Com. Par. Agr. [Mexico], Circ. 45, pp. 14, figs. 7*).—Brief mention is made of outbreaks of leaf-eating caterpillars on cabbage, grapes, sugar cane, cotton, and other fiber plants. Directions are also given for the preparation of arsenical insecticides for controlling these pests.

The caterpillar pest of indigo in Behar, H. M. LEFROY (*Agr. Jour. India, i (1906), No. 4, pp. 338-350, pl. 1, fig. 1*).—In some seasons the young indigo is badly damaged by the attacks of *Caradrina exigua*. This insect is described in its different stages with notes on its life history. The pest prevails in large numbers in April and May. Occasionally the insect is found on alfalfa and other crops, but does not do as much damage on them as on indigo. According to practical experience with this pest the Java-Natal indigo is almost immune and it is recommended that this variety be planted instead of Sumatran indigo. In some locations the use of alfalfa as a trap crop may also give favorable results.

The red slug caterpillar; a serious pest of the tea plant, H. H. MANN (*Indian Tea Assoc. [Pamphlet] 5, 1906, pp. 14, pls. 2*).—This pest was first observed on tea in 1895 and has since become very injurious. The eggs are laid in masses on the under side of leaves or on the main trunk of tea bushes. The egg-laying and hatching occupy about 12 days, while the larval period extends over 5 weeks and the pupal period over 21 days. A number of natural enemies are known, but these do not keep the pest in check. Unfortunately experiments thus far carried on with arsenicals have given rather unsatisfactory results. The pest may best be controlled by hand picking and this has been found to be quite a simple undertaking. The pest in question is referred to as *Heterusia exigula*.

The production of golden colored pupæ with *Vanessa urticæ* and *V. io*, E. MENSİK (*Ztschr. Ent., n. ser., 1906, No. 31, pp. 15-18*).—The author accidentally discovered a number of bright golden pupæ of *Vanessa urticæ* and some of a lighter color in *V. io*. An attempt was made to produce this color by a definite line of feeding the larvæ. It was found that when larvæ of *V. urticæ* were fed on nettle leaves from wet situations, the resulting pupæ showed a rich golden color in from 8 to 30 per cent of cases.

A supposed difference in the coloring matter of oak leaves and the silk of *Saturnia yama-mai*, C. GAUTIER (*Compt. Rend. Soc. Biol. [Paris], 61 (1906), No. 33, pp. 419, 420*).—It has been maintained that the green coloring matter of the cocoon of the *Saturnia yama-mai* may be differentiated from the chlorophyll of oak leaves by its insolubility in cold alcohol. The author shows, however, that both coloring matters are soluble in the same reagents.

Number of eggs of *Samia cecropia*, *Pulvinaria innumerabilis*, and *Culex pipiens*, J. J. DAVIS (*Ent. News, 17 (1906), No. 10, pp. 368, 369*).—As a result of repeated observations the author finds that the average number of eggs laid by a female *Samia cecropia* is 243.9, for *Pulvinaria innumerabilis* 3,410.2, and for *Culex pipiens* 178.4.

Camnula pellucida (*Com. Par. Agr. [Mexico], Circ. 47, pp. 7, figs. 6*).—This grasshopper causes considerable injury to grasses and cultivated crops in Mexico. In combating the pest the author recommends the cultivation of the breeding grounds, the use of hopperdozers, and spraying with crude petroleum or Paris green.

A scale insect of the cocoanut palm, E. FLEUTIAUX (*Agr. Prat. Pays Chauds, ii (1906), No. 41, pp. 166-168*).—In western Africa, particularly in Dahomey, a scale insect was observed in large numbers on the cocoanut palm which proved to be *Aspidiotus destructor*. A mixture containing soda and resin is recommended as a spray for this pest.

The large larch sawfly (*Nematus erichsoni*), R. S. MACDOUGALL (*Jour. Bd. Agr. [London], 13 (1906), No. 7, pp. 385-391, pl. 1*).—According to the author's observations this insect makes its most persistent attacks upon trees 20 to 70 years old, but may injure much younger trees. Little can be accomplished in fighting the adult insect, but the larvæ may be destroyed by jarring or by spraying with hellebore or arsenicals. Some help is also received from birds and other natural enemies of the pest.

The maple leaf-stem borer or sawfly, W. E. BRITTON (*Ent. News, 17 (1906), No. 9, pp. 313-321, pl. 1, fig. 1*).—An insect attack upon the petioles of the leaves of the sugar maple has been observed in some localities in Connecticut for the past 7 years. The larvæ of this pest develop from an egg laid at the base of the leaf and burrow through the petiole, which finally breaks off, causing the leaves to be shed in May or June. The insect has been identified as *Priophorus acerianalis*, a species of sawfly.

A few parasites have been reared from specimens of the sawfly. No good results can be expected in controlling this pest by application of insecticides to the tree. It is suggested, however, that since the larvæ fall from the tree and enter the ground about June 15, a large proportion of them might be destroyed by spraying the soil at this time with kerosene emulsion.

Constriction of twigs by the bag worm and incident evidence of growth pressure, H. VON SCHRENK (*Mo. Bot. Gard. Ann. Rpt., 17 (1906), pp. 153-181, pls. 9, figs. 4*).—It was noted that bag worms in attaching the band which holds the bag around the small twigs of arbor vite caused a swelling at the point where the band was applied and the subsequent death of the terminal portion of the twig. An anatomical study was made of the changes set up in the tissue of the twigs as a result of the attachment of the bag worms. A brief bibliography of the subject is appended to the article.

The recently introduced dung fly parasite, J. KOTINSKY (*Hawaii. Forester and Agr., 3 (1906), No. 10, pp. 319-321*).—A number of specimens of *Encoila impatiens* have been introduced and successfully colonized in Hawaii. This parasite attacks insects which live in dung. It is hoped that they will be of some benefit in controlling the horn fly.

The British woodlice, W. M. WEBB and C. SILLEM (*London: Duckworth & Co., 1906, pp. X+54, pls. 25, figs. 59*).—A monographic account is given of this group of Crustacea which are commonly known in the United States as sow bugs. The various species are described in detail and a bibliography of the subject is presented. Mention is also made of the economic relations of such species as are known to attack cultivated plants.

Ants, F. KNÄUER (*Ameisen. Leipzig: B. G. Teubner, 1906, pp. 156, figs. 61*).—This is a general treatise on the biology of ants and contains a discussion of the various forms found in ant colonies, care of the brood, construction of nests, and symbiosis of ants with other species of ants, unrelated insects, and plants.

The ant, K. ESCHERICH (*Die Ameise. Brunswick: F. Vieweg & Sou, 1906, pp. 232, figs. 68*).—In presenting a general account of ant biology the author makes a study of the geographical distribution and classification of ants, following this with a discussion of their morphology, anatomy, polymorphism, methods of reproduction, construction of nests, feeding habits, symbiotic relations, and intelligence.

Harvest mites, or "chiggers," F. H. CHITTENDEN (*U. S. Dept. Agr., Bur. Ent. Circ. 77, pp. 6, figs. 3*).—The pests commonly known as "chiggers" are the larval forms of harvest mites and are found on bushes, trees, and grass from which they infest man, burrowing in the skin and causing more or less serious inflammation. The remedies suggested by the author are hot baths with salt

and strong soap within a few hours after exposure, or the sprinkling of sulphur in the underclothes before going into localities where chiggers prevail. Various other local treatments may be applied such as soda, iodine, or alcohol, but the effects are usually temporary.

The destruction of mosquitoes in houses with pyrethrum, A. L. HERRERA (*Com. Par. Agr. [Mexico], Circ. 48, pp. 5, figs. 2*).—According to the author's experience houses may be ridden of mosquitoes by the thorough use of pyrethrum. The powder is distributed by means of small hand bellows and is not injurious to man even if applied in excess.

Contributions to the study of silkworms, K. TOYAMA (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1906), No. 2, pp. 225-393, pls. 7, chart 1*).—The author finds that polygamy is a normal habit of the silkworm and that fertilization is much more influenced by the condition of the females than by that of the males.

A parasitic fly (*Tachina rustica*) is reported as causing great losses among silkworms in Siam. The egg of the parasite is laid on the skin of the silkworm and the larva bores into the host. The parasite is described in its various stages. It appears to be distributed throughout the Indo-Chinese peninsula, in some cases from 70 to 80 per cent of the silkworms in a restricted locality being parasitized. The Siamese protect the silkworms by wrapping cotton cloth around each worm basket, while the Chinese use mosquito netting upon windows and doors.

A long series of experiments was carried on in crossing silkworms with special reference to determining whether the results conform with Mendel's law. It appears that in general the color of the cocoon and the egg and the various larval markings are inherited in accordance with Mendel's law, while the shape of the cocoon and various other characters follow some other law.

The length of the tongue of bees, N. KULAGIN (*Zool. Anz., 29 (1906), No. 24, pp. 711-716*).—A large number of measurements were made of German bees, American red-clover bees, and other varieties for the purpose of determining the relative length of the tongue. The tongue of dark races of bees in America and Russia appears to be distinguished by its length. Careful measurements, however, indicate but little difference in the length of these bees and dark German races. The average length of the tongue of dark bees was 6.21 mm. and of red clover bees 6.22 mm., the greatest observed length being 6.69 mm. in the dark bee. The average length of the tongue of Italian bees is greater than that of dark bees, while the longest tongues were found in Cyprian bees, the average being 6.5 mm.

Since the length of the nectar tube in red clover is 9 to 10 mm., it is evident that the existing races of bees are not capable of extracting honey from this plant.

The respiratory organs of bees, S. DYACHENKO (*Izv. Moscov. Sel'sk. Khoz. Inst. (Ann. Inst. Agron. Moscou), 12 (1906), No. 1, pp. 1-14, figs. 9*).—The anatomical features of the respiratory organs of bees are described in considerable detail by way of comparison with the respiratory organs of other insects.

The swarming of bees, SOPHIE DIATSCHENKO (*Ztschr. Wiss. Insektenbiol., 2 (1906), No. 9, pp. 285-288*).—The study of the causes and means of regulating the swarming of bees has always proved an interesting one to the entomologist and practical bee raiser. According to the author's observations swarming is more likely to occur in times of heavy or very light honey yield than during the period of moderate flow of honey. The regulation of swarming may easily be accomplished by furnishing a moderate amount of room for the bees of each colony.

The number of bees in a colony, J. DEVAUCHELLE (*Apiculteur, 50 (1906), No. 9, pp. 322-326*).—In estimating the weight and number of bees in a colony

more care should be exercised than is usually given to this matter. The author believes that as a rule there are about 10,000 bees per kilogram of weight.

Water for bees, R. BERNHE (*Jour. Dept. Agr. Victoria*, 4 (1906), No. 10, pp. 632-634, fig. 1).—Attention is called to the desirability of having a suitable water supply conveniently arranged for the use of bees. A practical apparatus for supplying water is described and illustrated.

Evaporation from hives at night, A. MAUJEAN (*Apiculteur*, 50 (1906), No. 9, pp. 326-332).—The loss of weight which takes place as a result of evaporation in hives during the night depends somewhat on the rapidity with which the bees cap over the cells already filled with honey. This process is delayed somewhat and a larger loss takes place than would otherwise be the case, but this is a matter which can not be controlled.

Artificial comb foundation, R. PINCOT (*Apiculteur*, 50 (1906), No. 10, pp. 361-368).—According to the author's observations, bees, if left to themselves, construct the worker cells according to their own anatomical proportions. The cells are, therefore, larger or smaller, according to the size of the bees which made them.

By starting the foundation in a matrix which gives comparatively large bases for the cells, larger cells are made and the worker bees which develop in such brood cells are larger than they otherwise would have been. Attention is called to the advantages of large size in bees and a description is given of the methods by which bees draw down the foundation to form the cell walls.

The bacteria of the apiary, with special reference to bee diseases, G. F. WHITE (*U. S. Dept. Agr., Bur. Ent. Bul. 17, Tech. ser., pp. 50*).—Reference has been made to previous work of the author along the line of bee diseases (*E. S. R.*, 16, p. 487), and the present bulletin contains a summary of the work thus far done.

In the first part of the bulletin descriptions are given of bacteria commonly found in the combs or pollen, and in or upon honey bees and other material with which they come in contact. Detailed statements are made regarding the behavior of these bacteria upon different nutrient media. As a rule, honey from the healthy hive is sterile. A number of bacteria, however, occur upon the comb and in the intestines of healthy bees.

As a result of the author's investigations the name European foul brood is given to the disease in which *Bacillus alvei* was found, while American foul brood is a term reserved for the brood disease due to *B. larva*. Both of these diseases have a similar distribution. So-called black brood is apparently identical with European foul brood and the term is therefore abandoned. Pickle brood and paralysis are not yet understood.

The brood diseases of bees, E. F. PHILLIPS (*U. S. Dept. Agr., Bur. Ent. Circ. 79, pp. 5*).—Two forms of brood disease commonly known as European and American foul brood are recognized in this country. American foul brood is distributed throughout nearly all parts of the United States, while European foul brood or black brood is not so widespread, but has caused great losses in many localities and is steadily on the increase.

The symptoms of these diseases are described and remedies are outlined. Drugs are of little avail and colonies may be treated by shaking into clean hives or excluding from old infested hives by means of bee escape.

Brief notes are also given on the symptoms of pickle brood and the conditions commonly known as chilled, overheated, and starved brood.

The enemies of bees, A. CAILLAS (*Apiculteur*, 50 (1906), No. 11, pp. 410-416, figs. 4).—Attention is called to a number of the natural enemies of bees, including certain grasses, swallows and other bee-eating birds, spiders, and parasitic moths.

FOODS—HUMAN NUTRITION.

Food and nutrition, ISABEL BEVIER and SUSANNAH USHER (*Urbana, Ill.: Authors, 1906, pp. 45*).—In this volume, which is designed primarily for the use of students in the household science department of the University of Illinois, a considerable number of experiments have been selected from a variety of sources for laboratory instruction on protein, fats, carbohydrates, meat, milk, and other foods, and on the digestion of proteids and starches.

The manual is expected to serve two purposes: "First, to aid the student to recall and to arrange in an orderly way the knowledge gained from other sources; secondly, to apply this knowledge, in so far as possible, to various kinds of food problems and so to serve as an introduction to individual work with foods which follows." A bibliography is appended which contains references to works in which the student can find fuller information.

Modern diet (*Brit. Med. Jour., 1906, No. 2384, pp. 581, 582*).—A critical discussion of nutritive requirements and of dietary standards with special reference to recent work on the subject. It is conceded that no immediate harm results to healthy individuals from a low proteid diet and that this conclusion is of importance in connection with diseases involving the kidneys and digestive organs. That many persons undoubtedly take excessive amounts of proteids in their diet is also pointed out. "We do not think, however, that it has been proved that a diet containing proteid in a much smaller proportion than that of 100 gm. a day for an adult of 70 kg. is permanently beneficial either to the individual or to the race and especially for those whose occupations require considerable muscular exertion. It appears, on the contrary, from the evidence at present at our disposal, that such a permanent reduction is not without possible danger to the virility of the nation."

The diet of the precibiculturists, H. CAMPBELL (*Brit. Med. Jour., 1905, Nos. 2322, pp. 40, 41; 2325, pp. 208, 209; 2328, pp. 350-352; 2329, pp. 406-409; 2333, pp. 665, 666; 2335, pp. 813-815; 2337, pp. 979-981; 2340, pp. 1217-1219; 2347, pp. 1658, 1659*).—A general discussion of prehistoric, savage, and semisavage tribes and their habits, special attention being paid to food, methods of preparation, and related questions.

The food of well-to-do classes, E. BIERNACKI (*Zentrbl. Gesam. Physiol. u. Path. Stoffwechsels, u. scr., 1 (1906), No. 13, pp. 401-403*).—The data collected regarding the food of 30 well-to-do families in Warsaw and Lemberg showed that the protein supplied per person per day varied from 78 to 195 gm. and the energy from 2,110 to 4,010 calories, being on an average 121 gm. protein and 3,015 calories.

Food and digestion in warm climates, J. CANTLIE (*Jour. Trop. Med. [London], 9 (1906), No. 20, pp. 312-316*).—The author calls attention to the fact that rice occupies much the same place in the oriental dietary as bread fills in that the western nations, and that the importance of this foodstuff is very commonly greatly overestimated in discussions of the diet of oriental races.

In his discussion of Chinese dietary habits, which is based on personal experience, the author states that "their early morning meal consists of soft-boiled rice 'conjee,' . . . The forenoon meal, or breakfast, consists of fish, or fat pork, vegetables, rice, and tea. The midday meal may be again soft-boiled rice, but the afternoon or evening meal consists also of fish, pork, vegetables, rice, and tea. The rice is in no larger proportion to the meal, perhaps not quite so large, than is bread in the European breakfast."

The food materials, particularly of animal origin, which are available in tropical regions are discussed, as well as other general topics. Attention is directed to the extended use of hot spices, particularly in the form of curry.

"The use of pepper is, of course, an oriental custom, and the stronger forms of pepper seem requisite as an article of diet. The therapeutic use of pepper seems to be not so much a stomachic tonic as an intestinal stimulant, and chiefly as a stimulant to the large intestine."

A diet with and without meat and a vegetarian diet, K. BORNSTEIN (*Ther. Gegenwart*, 77 (1906), No. 5, pp. 193-198).—The author speaks in favor of a mixed diet with a moderate amount of meat, though he recognizes the fact that a diet without meat may be entirely sufficient provided care is taken to secure a sufficient amount of digestible protein. He states that an excessive amount of meat increases intestinal fermentation and uric acid, while this is not the case with a vegetarian diet.

The hay-box cook book, SARAH P. REDFIELD (*Chicago: Author, 1906*, pp. 36).—As the author points out, the principle underlying the so-called hay-box cookery is the retention of heat in materials which have been brought to a boiling point on a range or stove. This is accomplished by surrounding the vessel containing the hot food with nonconducting material.

The construction of a homemade hay-box cooker is described, and detailed directions given for the preparation of a number of foods with such a cooker.

Fireless cooking, H. G. SHARPE (*Rpt. Commis. Gen. [U. S. Army], 1906*, pp. 14-18).—A brief progress report is made of experiments on cooking by surrounding the hot food with nonconducting material. "Exhaustive experiments have been made, not only in cooking in garrison, but also in the field under varying conditions, and the results in both instances have been gratifying."

Some data are also given regarding army training schools for bakers and cooks, emergency rations, an especially constructed kitchen car and other questions concerning army rations or their preparation.

Good luncheons for rural schools without a kitchen, ELLEN H. RICHARDS (*Boston: Whitecomb & Burrows, 1906*, pp. 12).—As the author points out, satisfactory lunches for school children may be prepared with the simplest apparatus by cooperation on the part of pupils and teachers. Such an enterprise should include instruction in home economics, and suggestions are made for carrying on the work in schools without interfering with the regular curriculum. Data are quoted showing the satisfactory results which have attended such efforts.

The bleaching of flour, E. FLEURENT (*Compt. Rend. Acad. Sci. [Paris]*, 142 (1906), No. 3, pp. 180-182).—According to the author, the only satisfactory commercial method for the bleaching of flour depends upon the use of nitrogen dioxid produced either by chemical means or by the action of an electric arc in the atmospheric air. The quantity of oxid of nitrogen (calculated as dioxid) required for bleaching varies from 15 to 40 cc. per kilogram flour and varies according to the nature of the flour. The action of the nitrogen dioxid is due mainly to the formation of additive products with the flour fat as shown by the fact that the iodin numbers are increased.

Bleaching with nitrogen dioxid may be detected by methods based on the color tint of the saponified fats. It does not affect the diastase or the various ferments of flour. The resistance of the fats to saponification is directly proportional to the amount of the dioxid absorbed.

The action of ozone on flour is markedly different from that of nitrogen peroxid and also from the slow action of atmospheric air. Ozone increases the iodine value and favors the production of volatile fatty acids, while nitrogen peroxid does not. On the other hand, 4 months exposure to air nearly doubles the total acid content in normal flour, while ozone has no effect on total acid.

Liebig's meat extract, II, F. KUTSCHER (*Ztschr. Untersuch. Nahr. u. Genussm., 11 (1906), No. 10, pp. 582-584*).—Continuing earlier work (E. S. R., 17,

p. 790) the physiological and chemical properties of newly identified constituents of meat extract were studied. Ignotin was found to have no physiological action. Oblitin and novain, on the other hand, in experiments with animals, caused illness. Oblitin undergoes cleavage in the body, the principal cleavage product, novain, being found in both urine and feces, and apparently there is a close relation between these two bases.

Composition of Italian tomato juices, C. FORMENTI and A. SCIPIOTTI (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 12 (1906), No. 5, pp. 283-295).—Detailed analyses are reported of a number of samples of tomato juices, concentrated tomato extract, and tomato fruits.

As regards the amount of salicylic acid naturally occurring in the tomato, the figures given range from 15 to 25 mg. per kilogram of fresh fruit juice. A study of the tin in canned tomato juices showed that there was a marked increase if the material was allowed to remain in the can after opening.

Concerning the composition of tomatoes and tomato juice, W. STÜBER (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 11 (1906), No. 10, pp. 578-581).—Proximate and ash analyses are reported. Apparently all the acid present was citric acid. In no case was tartaric, malic, or succinic acid found. Fructose was more abundant in the juice than glucose.

Some data are also given regarding the examination of a commercial tomato purée.

Concerning elderberry juice, H. LÜHRIG (*Pharm. Centralhalle*, 46 (1905), pp. 829-831; *abs. in Ztschr. Untersuch. Nahr. u. Genussmitl.*, 12 (1906), No. 8, p. 485).—Analyses of 10 samples of elderberry juice are reported.

Honey, T. MACFARLANE (*Lab. Inland Rev. Dept. [Canada] Bul.* 122, pp. 11).—Of 54 samples of honey examined 9 were adulterated, although in only one case was adulteration declared.

Adulterated glucose used in candy making, C. D. HOWARD (*N. H. Sanit. Bul.*, 2 (1906), No. 12, pp. 209-211).—Glucose, according to the author, enters to a greater or less extent into the manufacture of practically all the cheap candy now on sale. To overcome a tendency to stickiness some confectioners make a practice of adding a concentrated solution of bisulphite of soda to the glucose. Bisulphite of soda is also used as a bleaching agent in the manufacture of glucose. Examination of a number of samples of confectioners' glucose showed the presence of sulphite equivalent to 0.0448 to 0.1056 gm. of the free acid per 100 gm. glucose. In one sample no sulphurous acid was found. In cheap candies examined the sulphurous acid ranged from traces to 0.036 gm. per 100 gm. of candy. Two of the samples contained no sulphurous acid.

"Whether the bisulphite is added by the refiner on account of any specific advantage accruing from such to the confectioner, or whether such use is for bleaching purposes, is immaterial in connection with the point at issue which is that the presence of such material, under the law, constitutes an adulteration, and vendors of candy thus adulterated will be liable to prosecution."

Food materials and their adulterations, ELLEN H. RICHARDS (*Boston: Whitecomb & Barrows, 1906, 3. ed., pp. VIII+176*).—Information is summarized regarding the principles of dietetics, the characteristics of the more important food materials, the more usual forms of food adulteration and sophistication, and related questions. The volume has been revised to include new material which has accumulated since it was first published. A bibliography is appended.

Simple household tests for the detection of adulterations in foods, J. PETERSON (*Salt Lake City: Utah Dairy and Food Commission, 1906, pp. 15*).—In this pamphlet, which was prepared by the Utah Dairy and Food Commission, simple tests are given to aid the housewife to determine the character and quality of a number of common foods.

Report of food inspection, C. D. HOWARD (*N. H. Sanit. Bul.*, 2 (1906), No. 12, pp. 198-209).—Of 488 samples of canned meats, soups, and vegetables, candies, dried fruits, flavoring extracts, sirup, spices, coffee, cocoa, etc., 186 samples were found to be adulterated, misbranded, or below the required standard.

Food inspection in Saxony, C. B. HURST (*Mo. Consular and Trade Rpts.* [U. S.], 1906, No. 313, pp. 121-124).—In Saxony the inspection of food is under the direct control of the government and is organized into 2 state institutions, 3 municipal inspection laboratories, and 11 subordinate laboratories. The operation of the law is briefly described. According to the author, marked benefits have resulted from this food inspection.

The effect of preservatives, A. BEHRE and A. SEGIN (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 12 (1906), No. 8, pp. 461-467).—The preservative powers of formaldehyde, benzoic acid, salicylic acid, boric acid, sodium benzoate, sodium thio-sulphate, sodium sulphite, and a commercial preservative were tested with meat juice. Formaldehyde gave the best results. At the end of 13 days the meat juice preserved with it was unchanged as regards color and odor. Of the other materials tested the acids gave better results than the salts.

Influence of food preservatives and artificial colors on digestion and health. II, Salicylic acid and salicylates, H. W. WILEY (*U. S. Dept. Agr., Bur. Chem. Bul.* 84, pt. 2, pp. VI+479-760, figs. 3).—The experiments here reported in full have been noted from the author's summary of results (E. S. R., 18, p. 462).

The injurious effects of sulphurous acid and its compounds with special reference to free sulphurous acid, H. WALBAUM (*Arch. Hyg.*, 57 (1906), No. 2, pp. 87-144).—An aqueous solution of free sulphurous acid, like the gaseous form, is very irritating and often more or less injurious. Very small amounts, 4 or 5 mg. in the form of a 0.02 per cent solution or certainly 10 mg. in a 0.04 per cent solution, cause subjective symptoms in man. The salts are similar in their effects to the acid, owing to the fact that the free acid is liberated in the digestive tract. Compounds of sulphurous acid with glyucose and acetaldehyde are the principal organic forms in which it occurs. In no case should sulphured fruits contain more than an equivalent of 10 mg. of the acid per 100 gm.

The question of sulphurous acid compounds in wine is also considered.

Determining the limits within which sulphurous acid in foodstuffs is harmful, JAKOBS and H. WALBAUM (*Arch. Expt. Path. u. Pharmacol.*, 54 (1905), No. 6, p. 421; *abs. in Zentbl. Physiol.*, 20 (1906), No. 8, p. 288).—The investigations reported have been noted above from another publication.

The mechanics of stomach digestion, A. SCHEUNERT (*Arch. Physiol. [Pflüger]*, 114 (1906), No. 1-2, pp. 64-92, figs. 30).—From a number of experiments the conclusion was reached that foods taken one after the other form layers in the stomach and do not mix. The formation and persistence of the layers is influenced by the anatomical structure of the stomach, its position in the abdominal cavity, and other conditions.

The failure of stomach contents to mix explains why with herbivora starch digestion may progress actively at the cardiac end of the stomach where lactic acid is present in abundance and other fermentations are taking place, though it ceases in other portions where hydrochloric acid is present.

The theory that throughout its progress stomach digestion is of the same character and that the stomach contents are a uniform mixture is, in the author's opinion, erroneous.

The mechanics of stomach digestion, ELLENBERGER (*Arch. Physiol. [Pflüger]*, 114 (1906), No. 1-2, pp. 93-107).—On the basis of the preceding article and earlier work (E. S. R., 17, p. 485) the mechanics of stomach digestion is discussed.

The energy required for the work of digestion, O. COHNHEIM (*Arch. Hyg.*, 57 (1906), No. 4, pp. 401-418).—Digestion requires more energy production than hunger, the amount measured in the experiment reported being 3.3 calories equivalent to 0.98 gm. carbon dioxide or 0.35 gm. fat, an increase of 9 per cent of the minimum energy metabolized per day at rest and in a warm room, and not over 1 per cent of the output of energy per day under normal conditions. This increase is due to the work of the digestive organs. The total nitrogen excretion was not increased. It appears, therefore, that the work of digestion, like muscular work, is carried on at the expense of nitrogen-free nutrients.

The digestion of protein and its function in general nutrition, LAMBLING (*Rev. Sci. [Paris]*, 5, ser., 6 (1906), No. 18, pp. 545-551).—A summary and discussion of recent work pertaining to the cleavage and digestion of proteids.

Peptic digestion, P. MEY (*Ztschr. Physiol. Chem.*, 48 (1906), No. 1, pp. 81-84).—The albuminoses formed in gastric digestion can be almost completely precipitated by the use of tannin, a peptone remaining in the filtrate.

The effect of different substances upon artificial peptic digestion, J. VON FUJITANI (*Arch. Internat. Pharmacod. et Théor.*, 14 (1905), p. 1; *abs. in Hyg. Rundschau*, 16 (1906), No. 19, pp. 1083, 1084).—Among the materials studied were tea, coffee, and sugar products.

Tea and coffee in concentrated solution were found to have an unfavorable effect upon peptic digestion directly proportional to the degree of concentration. Apparently the caffeine present did not exercise any effect upon digestion. Sugar solutions of over 0.5 per cent concentration had a retarding effect upon digestion.

New comparative studies of natural and artificial digestion of protein, W. ROTHÉ, H. WANGNICK, and A. STUTZER (*Jour. Landw.*, 54 (1906), pp. 257-264).—The same results were obtained in artificial digestion experiments as in the natural experiments with rabbits, the feeding stuffs used being wheat, bran, and meadow hay.

Muscular work and protein metabolism, W. SAWJALOW (*Ztschr. Physiol. Chem.*, 48 (1906), No. 2, pp. 85, 86).—An examination of liquid which was passed through isolated cat and rabbit hearts kept at work from 1 hour and 30 minutes to 2 hours and 30 minutes showed that it was almost entirely free from ammonia and from urea. This led to the conclusion that muscular work was apparently performed without the cleavage of protein.

The physiology and pathology of mineral metabolism, with tables showing the ash constituents of foods, condiments, and mineral waters, A. ALBU and C. NEUBERG (*Physiologie und Pathologie des Mineralstoffwechsels nebst Tabellen über die Mineralstoffzusammensetzung der menschlichen Nahrungs- und Genussmittel sowie der Mineralbrunnen und -Bäder*. Berlin: Julius Springer, 1906, pp. 247; *rev. in Zentbl. Gesam. Physiol. u. Path. Stoffwechsels*, n. ser., 1 (1906), No. 1, p. 464).—Among the subjects considered in this handbook are the water and ash content of the human body, the ash content of different organs, blood, and secretions; the dynamics of salt action; the physical-chemical action of salts; metabolism of calcium, magnesium, and other individual ash constituents; iodine, arsenic, and other elements occurring in small quantities; the therapeutics of ash constituents, and a critical discussion of methods of ash analysis. The tables contain a summary of data which the authors consider reliable, supplemented by the results of many original analyses.

As a whole, this volume constitutes a useful handbook on a subject on which hitherto information has been inadequate and widely scattered.

Influence of the quality and quantity of protein consumed upon the elimination of uric acid xanthin compounds in normal man, H. LABBÉ and L. FURET (*Compt. Rend. Soc. Biol. [Paris]*, 61 (1906), No. 27, pp. 214-216).—Experiments showed that the amount of uric-acid xanthin bodies produced from

protein of different sorts varied considerably, the following amounts being obtained per 100 gm. of the proteids studied: Herring 2.81 per cent, beef 1.65 per cent, macaroni 1.58 per cent, egg 1.56 per cent, and milk 0.71 per cent.

In a second test, milk, gruyère, and white cheese were compared, the amount of xantho uric bodies formed being greatest with the milk and least with the white cheese. The effect of the quantity of protein eaten upon xantho uric-acid excretion was also considered.

The influence of climatic factors, muscular work, and baths upon the excretion of water vapor through the skin, A. J. KALMANN (*Arch. Physiol. [Pflüger]*, 112 (1906), No. 11-12, pp. 561-599, pls. 2, fig. 1).—From tests in which muscular work was a factor the conclusion was reached that it caused an increase in the amount of water vapor given off through the skin, which was proportional to the character and amount of the work and especially to the temperature of the surrounding air and the degree of moisture which it contained. Cooling the skin resulted in a marked decrease in the amount of water vapor given off through it.

Fatigue, F. S. LEE (*Jour. Amer. Med. Assoc.*, 46 (1906), No. 20, pp. 1491-1500, figs. 5).—A general discussion of the causes and relief of fatigue in which much of the literature of the subject is summarized. As the author points out fatigue and recovery are phenomena of metabolism and only the assimilation and detoxication of the fatigue substances contained in the tissues "that normally come with rest—and, best, rest with sleep—are capable of adequate restoration of working power."

Influence of age on the calcium content of the blood, C. DIHÉRE and G. L. GRIMMÉ (*Compt. Rend. Soc. Biol. [Paris]*, 60 (1906), No. 22, pp. 1022, 1023).—In dogs, the proportion of calcium in the blood decreased regularly as age increased. With rabbits the proportion varied greatly with individuals of the same age and did not appear to be directly proportional to the age. Generally speaking, the calcium content of rabbit blood was about double that of dog blood.

The physiology of taste, W. STERNBERG (*Geschmack und Geruch-Physiologische Untersuchungen über den Geschmackssinn. Berlin: J. Springer, 1906, pp. 150; rev. in Brit. Med. Jour., 1906, No. 2393, p. 1309*).—A summary and discussion of available data on the physiology of taste, methods of measuring taste, and related questions.

ANIMAL PRODUCTION.

The feeding of farm stock, F. W. TAYLOR (*New Hampshire Sta. Bul.* 127, pp. 187-207).—The composition and digestibility of feeding stuffs, feeding standards, palatability of rations, and related questions are discussed, tables of composition are given, and the computation of rations explained by examples.

"The economic feeding of stock should be the feeder's primary object.

"Economic feeding must go hand in hand with scientific feeding.

"The principles of scientific feeding have been carefully worked out by skilled investigators and feeders.

"The application of these scientific principles is a very simple process involving only the rules of common arithmetic.

"Every farmer can and should apply these principles in his everyday practice.

"A careful study of the market prices on feeds and an inspection of their guarantee tags will mean money in pocket to the farmer."

Steer feeding, J. J. VERNON and J. M. SCOTT (*New Mexico Sta. Bul.* 57, pp. 13, pls. 2).—Continuing earlier work (E. S. R., 16, p. 189), the comparative

value of alfalfa hay with and without grain was studied with 2 lots of 5 steers.

On alfalfa hay ad libitum with about one-third of a full ration of wheat and bran 3:1 the average daily gain in 118 days was 1.86 lbs. per head and each pound of gain required 9.12 lbs. grain and 1.12 lbs. alfalfa hay. On alfalfa hay ad libitum without grain the average increase was 1.73 lbs. per head per day, 11 lbs. of hay being required per pound of gain. Reckoning alfalfa at \$3.50 per ton a pound of gain cost 2.76 cts. on a ration containing grain and 1.92 cts. on hay only. The calculated returns per ton of alfalfa hay in the 2 cases were \$7.38 and \$8.36, respectively. "If we take an average of the 3 years' feeding tests we find that the lots receiving a grain ration made a slightly larger daily gain per 1,000 lbs. live weight than did the lots receiving alfalfa hay only. It required nearly 1 lb. more food for a pound of gain for those receiving alfalfa hay only than for the grain-fed lot. The cost of 1 pound of gain was higher when a grain ration was fed than when alfalfa was fed alone."

Feeding prickly pear to stock in Texas, D. GRIFFITHS (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 91, pp. 23*).—This bulletin, which supplements Bulletin 74 of the Bureau of Plant Industry (E. S. R., 17, p. 65), contains notes on the forms of prickly pear and gives the results of feeding tests with cows and steers. The method of feeding this plant was that commonly employed upon ranches in southern Texas where the experiments were conducted.

In tests with two cows prickly pear was compared with sorghum hay. The complete data including weather observations are reported. "A full roughage ration of pear with a constant grain ration appears to yield fully as good results as a full roughage ration of sorghum hay. The records are really a little more favorable to the pear ration." The prickly pear ration including 12 lbs. of rice bran and 3 lbs. of cotton-seed meal cost 13.05 cts. per cow daily. This allowed for the labor and gasoline required in singeing the cactus. It is stated that prickly pear has been fed to a dairy herd for 2 to 4 months each year for 6 or 8 years with no complaint from customers which could in any way be attributed to pear feeding.

A lot of 27 steers was kept in a 4-acre feeding lot and fed chopped prickly pear with cotton-seed meal. The largest and most woody plants available were selected, chopped without singeing, and fed in troughs early in the morning and about the middle of the afternoon. The cotton-seed meal was sprinkled on the chopped prickly pear. The average daily gain in the 105 days of the test was 1.75 lbs. per head, 55.03 lbs. of prickly pear and 2.5 lbs. of cotton-seed meal, at a total cost of 3.48 cts., being required per pound of gain. When shipped to market the average shrinkage per steer was 88.5 lbs.

Notes on the prickly pear, E. A. NOBBS (*Agr. Jour. Cape Good Hope, 29 (1906), No. 5, pp. 637-642*).—In connection with a discussion of the spread of prickly pear in Cape Colony, the desirability of eradicating it, and related questions, the statement is made that in times of droughts singed prickly pear is used as a feeding stuff for farm animals.

On the whole, the author concludes, prickly pear is not a wholesome feeding stuff and is at best only a makeshift during a time of drought. The fruit, as pointed out, is used as human food and is also used in the manufacture of a distilled spirit.

A study of the metabolism and physiological effects of certain phosphorus compounds with milch cows, W. H. JORDAN, E. B. HART, and A. J. PATIEN (*New York State Sta. Tech. Bul. 1, pp. 59; Amer. Jour. Physiol., 16 (1906), No. 2, pp. 268-313*).—The experiments reported were undertaken with a view to ascertaining the comparative value of different phosphorus compounds occurring in feeding stuffs, particularly phytin, a phosphorus compound occurring in bran in which an organic radical is coupled with calcium, magnesium,

and potassium. "Phytin is widely distributed in nature, and has been found in the seeds of red fir, pumpkin, peas, beans, white and yellow lupines, potatoes, and wheat."

Phytin may be completely or nearly removed from wheat bran by washing with water, but more easily by allowing the bran to undergo a slight fermentation, followed by leaching with water.

The experiments were made with 2 cows, and the income and outgo of nitrogen and phosphorus were studied on high phosphorus rations made up of oat straw, hominy or rice meal, whole-wheat bran, and wheat gluten, and low phosphorus rations in which rice, wheat gluten, and oat straw were combined with washed wheat bran. "Through the use of the wheat gluten, which contained from 70 to 75 per cent of protein, it was easy to regulate the protein supply so as to make it fairly uniform in the rations compared."

Quotations from the authors' summary and discussion follow: "The amount of outgoing phosphorus rose and fell with the quantity supplied in the food, though within narrow limits. When the phosphorus supply was abundant there was a storage of this element in the bodies of the animals, but during prolonged periods in which the supply of phosphorus was deficient there was withdrawn from the body store about 10 gm. daily in several periods.

"Through catabolic changes the phosphorus of the phytin and that of the unused digested nucleo bodies was reduced to inorganic combinations, and was excreted chiefly in the feces, though to a small extent in the urine. . . .

"The rise and fall in the amounts of outgoing phosphorus compounds occurred almost wholly with the inorganic salts found in the egesta. The organic phosphorus bodies of the egesta were but little affected, if at all, by the proportions of phosphorus compounds in the food. Variations in the phosphorus supply appeared not to modify the appropriation of this element by the milk.

"No relation whatever appears to exist between nitrogen excretion and phosphorus excretion.

"It is shown without question that the physiological effect of the two rations, due to the withdrawal from the bran of such compounds as were soluble in slightly acidulated water, differed to a marked degree. With the washed bran ration as compared with the one containing the unwashed bran, the following differences were observed:

"(a) Drier and much firmer feces with the washed bran ration, accompanied by a constipated condition, requiring in some cases the use of a purgative.

"(b) A marked disturbance of appetite in [one] experiment . . . when a sudden change was made from the washed bran ration to the one containing the unwashed bran, indicating some specific physiological influence of the compound or compounds removed from the bran by leaching.

"(c) A greatly reduced flow of urine followed a change from the unwashed bran to the washed bran ration, the reverse taking place when a reverse change was made.

"(d) An increase in the flow of milk consequent upon the withdrawal from the ration of the phytin and other water-soluble constituents of bran.

"(e) A reduction, sometimes large, in the percentage of fat in the milk consequent upon the withdrawal from the ration of phytin and other water-soluble constituents of bran.

"(f) A decreased production of butter fat during the period the washed bran ration was fed, notwithstanding a somewhat increased flow of milk.

"(g) The entire cessation of the œstrum period with cow 1 and a temporary disturbance of this period with cow 2. . . .

"The difference in effect of the two rations may be due to the larger supply of phosphorus in one ration without reference to the form of combination.

"The compound known as phytin may have specific physiological influences in several directions.

"The withdrawal from the ration of the basic compounds with which phosphorus is associated in the compound phytin may explain wholly or in part the peculiar physiological influences observed."

The laxative effects observed with phytin suggested that such conditions when noted with whole-wheat products can be assigned to this constituent rather than to their mechanical condition. With this point in view, the phosphorus content was determined in a number of milling products ground from the same lot of wheat and found to be as follows: Whole wheat 0.378 per cent, bran 1.280 per cent, middlings (ships) 0.857 per cent, germ 0.765 per cent, straight flour 0.089 per cent, first break flour 0.089 per cent, second break flour 0.088 per cent, third break flour 0.088 per cent, first middlings 0.071 per cent, second middlings 0.079 per cent, third middlings 0.091 per cent, germ roll flour 0.074 per cent, tailings or last roll 0.135 per cent, tailings (reel) 0.134 per cent, bran duster flour 0.196 per cent, and low-grade flour 0.166 per cent.

The authors note that middlings is the millers' term for fine flours.

"It is evident, as is well known, that the phosphorus compounds of the wheat kernel are found mainly in the outer coatings and germ from which are derived the bran and middlings. As the bran phosphorus is mostly contained in the compound phytin, it is self-evident that this substance exists in much larger proportion in the whole wheat bread than in fine flour. These statements are offered as suggesting a problem for further study."

Fattening pigs on corn and tankage, E. A. BURNETT (*Nebraska Sta. Bul.* 94, pp. 12).—The value of animal by-products as feeding stuffs and the effect of different rations on the strength of bones were studied.

A lot of 6 pigs fed soaked corn for 8 weeks made an average daily gain of 1.16 lbs. per head at a cost of 3.76 cts. per pound, and required 5.3 lbs. of feed per pound of gain. A similar lot of 7 pigs fed soaked corn with 5 per cent tankage made a daily gain of 1.44 lbs. per head at a cost of 3.55 cts. per pound and required 4.58 lbs. of feed per pound of gain. Similar values for a lot of 6 pigs fed soaked corn and 10 per cent tankage for 6 weeks were 1.3 lbs., 4.32 cts., and 5.16 lbs.

In a second test made with 3 lots of 10 lighter pigs and covering 8 weeks, the average daily gain on soaked corn was 1.26 lbs., on the smaller tankage ration 1.51 lbs., and on the heavier tankage ration 1.53 lbs. per head per day, the cost of a pound of gain in the 3 cases being 3.04, 2.88, and 3.09 cts., and the feed required per pound of gain 4.16, 3.71, and 3.66 lbs.

In a third test in which shelled corn was used 8 pigs fed corn and shorts 4:1 for 8 weeks gained 0.75 lb. per head per day, the feed required per pound of gain being 4.58 lbs. and the cost of a pound of gain 3.35 cts. The gains were the same on corn with 5 per cent tankage and on corn with 10 per cent tankage, namely, 1.03 lbs. per head per day, the feed required per pound of gain being 3.45 lbs. and 3.49 lbs., respectively, and the cost of a pound of gain 2.67 and 2.93 cts.

In the first of the tests some green sorghum was fed and in the other 2 tests the pigs were pastured on alfalfa, but no account was taken of the green feed eaten.

"The experiments with relatively mature animals have all shown that the addition of 5 per cent tankage to the ration produced cheaper gains than when 10 per cent tankage was used. With young pigs the gains were made on smaller amounts of food when the larger amount of tankage was added to the ration, but

the high cost of the tankage has made the smaller amount of tankage more profitable.

"A notable advantage in the feeding of tankage is seen in the more rapid gains made by the hogs and the consequent shortening of the feeding period.

"Another argument for tankage is that it is a concentrated protein food. Only a small amount is required to produce the result desired.

"In all the experiments made at this station, the hogs fed tankage consumed more feed, made larger gains, and were not easily put off feed, while the hogs fed straight shelled corn were easily thrown off feed after the first 6 weeks, consumed less feed, and made slower gains. From the limited test made we advise adding the tankage to the soaked corn just before feeding, rather than mixing with the corn before soaking and allowing the tankage time to soak and possibly become rancid before feeding."

In the test in which the effect of feed on the strength of bones in growing pigs was studied the rations fed the 4 lots, each containing 9 pigs, for 12 weeks consisted of soaked corn alone and with 10 per cent tankage, 10 per cent ground bone, and 25 per cent shorts, respectively. For the succeeding 4 weeks 10 per cent of the corn was replaced by alfalfa hay in each ration and then, as the alfalfa hay was not eaten readily, the unthrifty pigs (1 from each lot) were discarded and the original ration was resumed for 5 weeks. At the beginning of the test the weight of the pigs ranged from 57 to 66 lbs. on an average. The smallest gain, 114 lbs., was noted with the lot fed the corn ration and the greatest gain, 164 lbs. per pig, with the lot fed ground bone. Three pigs in each lot were slaughtered and the strength of the leg bones determined with a testing machine. Considering the average for 2 bones in each leg, the bones were markedly stronger in the case of the pigs fed the animal by-products, 1,081 lbs. (the highest value) being required to cause breaking in the case of the ground-bone fed lot as compared with 714 lbs. (the lowest value) in the case of the corn-fed lot. Similar results were noted with the fore leg radius bone and the lower hind leg tibia.

After continuing the feeding for 4 weeks 4 pigs in each lot were killed and the breaking tests repeated. As before, the strongest bones were noted with the lot which had received animal by-products, the average values (8 bones) ranging from 424 lbs. with the corn-fed lot to 1,057 lbs. with the lot fed tankage.

"It is apparent from these results that the feeding of tankage or ground bone to young growing pigs produces a very marked effect on the strength of bone when compared with a corn ration and that its influence is still marked when compared with corn and shorts on alfalfa pasture."

The test is regarded as preliminary and final conclusions are not drawn.

Analyses of commercial feeding stuffs, J. E. HALLIGAN (*Louisiana Stas. Bul.* 88, pp. 61).—In carrying out the provisions of the State feeding-stuff law 1,815 samples were analyzed, including cotton-seed meal, rice bran, molasses feeds, corn and oat feeds, wheat bran and mixed feed, brewers' grains, commercial and proprietary feeds, and beef scraps and similar poultry feeds. Special fiber determinations were also made in 123 samples of feeding stuffs.

"Good wheat bran is a scarce article in Louisiana. Some of these brans are adulterated with oat offal, and contain screenings. . . .

"Many of the mixed feeds sold in this State are adulterated with ground corn-cobs. These feeds came up to their guarantee in most cases, but the consumer in buying these feeds pays fully as much as for the genuine article. A true mixed feed, under this head, is composed of bran and middlings in varying proportions. The consumer should demand a mixed feed carrying at least 16.50 per cent protein.

"There have been very few samples of . . . [condimental] feeds received in this laboratory. These feeds are a mixture of sulphur, salt, saltpeter, epsom salts, Glauber's salts, sodium bicarbonate, fenugreek seeds, fennel seeds, charcoal, red and black peppers, ground bone, venetian red, and anise. This class of feeds generally carry attractive names, and the manufacturers make great claims regarding their curative properties. These feeds are too expensive for the economical feeder.

"If your animals are in good health they need no condition powders or tonics, and if they are sick it is cheaper to consult a veterinarian."

Commercial feeding stuffs in Pennsylvania in 1905, F. D. FULLER (*Penn. Dept. Agr. Bul. 145, pp. 51*).—The 339 samples of feeding stuffs examined under the provisions of the State feeding-stuff law included cotton-seed meal, linseed meals, flaxseed meals, distillery and brewery by-products, gluten meal and other corn by-products, corn meal, corn-meal feed, corn flour, low-grade wheat flour, wheat middlings, wheat bran, bran and middlings, oat by-products, mixed and proprietary feeds, proprietary poultry feeds, barley, barley feeds, and dried sugar-beet pulp.

Of the wheat offals examined, 11 were deficient in fat, 13 in protein, and 22 in both protein and fat. Six feeds were found to be adulterated, namely, "wheat bran with rice hulls, wheat bran with corncob, 'chop' (corn and light oats) with coffee hulls, 2 samples of corn and oats chop, and 1 sample of corn, oats, and barley with oat hulls. Wheat offals were inferior in quality, which was due largely to climatic conditions.

"The oat feeds on the market contain a large proportion of oat hulls. There are on the market, however, a large variety of feeding stuffs of good quality from which the farmer should have no difficulty in choosing those best adapted to his need. As long as the farmer can raise plenty of corn, hay, and oats he can not afford to purchase any feeding stuff containing less than 14 per cent of protein."

The poisonous properties of peanut-oil cake, E. KRÜGER (*Chem. Ztg., 30 (1906), No. 81, p. 999*).—Brief notes are given regarding a case of poisoning attributed to ground peanut-oil cake. In the author's opinion, this was due to the accidental presence of castor bean, to decomposition, or to some similar cause, as investigations failed to reveal toxic properties and other portions of the same consignment of meal were apparently harmless.

Purin bodies in the urine of pigs, cattle, and horses, A. SCHITTENHEIM and G. BENDIX (*Ztschr. Physiol. Chem., 48 (1906), No. 2, pp. 140-144*).—The amount of purin bases in pigs' urine is greater than that of uric acid and increases markedly in hunger. In cattle the ratio is about the same as with man, namely, considerable uric acid and little of the basic bodies. With horses, according to the author, the amount of purin bases is 7 or 8 times as great as the amount of uric acid. Apparently the purin metabolism of different kinds of animals varies markedly.

The effect of raw meat on young animals, C. RICHEL (*Compt. Rend. Acad. Sci. [Paris], 142 (1906), No. 9, pp. 522-524*).—The experiments were made with young dogs and covered 6 months. In 3 of the tests cooked meat alternated in 5-day periods with porridge (made of rice, milk, and sugar), with raw meat, and with cheese. In the 4 remaining tests a diet of cooked meat, raw meat, porridge, and cheese alternated in 5-day periods, with fasting periods of like duration. In the feeding periods in which the diet varied the dogs remained in good condition. When fasting during each alternate period the most satisfactory results were obtained on raw meat. The dogs lost 10 per cent of their weight in 3 months, then made good the loss and practically maintained a con-

stant weight. On cooked meat the animals remained in good health, but lost 20 per cent in weight. The dogs fed the porridge of rice, milk, and sugar all died before the conclusion of the experimental period, as did 2 of those fed cheese.

In the author's opinion, the experiments demonstrated the great value of raw meat, especially as an aid to the recuperative powers, and he believes that this is dependent not alone upon the quantity of protein present, but upon some quality which is lessened by cooking. The experiments as a whole were undertaken as an outcome of the author's interest in the value of raw meat in the treatment of tuberculosis.

Report on the poultry industry in America, E. BROWN (*London: Nat. Poultry Organ. Soc., 1906, pp. VIII+124, pls. 8, fig. 1*).—In this report the author discusses the methods of poultry raising in Canada and the eastern United States, systems of feeding, incubation and rearing, egg production, table poultry, duck farming, turkey raising, marketing of eggs and poultry, inspection work at the agricultural colleges and farmers' institutes, experiment station work pertaining to poultry, government assistance in poultry raising, and related questions. The data presented are the result of a special tour of inspection. Some of the conclusions drawn follow:

"American experience proves the importance of securing immunity from taint in the soil, either by the adoption of double yards to permanent houses, with use and cultivation of the ground in alternation, or by systematic removal to fresh ground, thus confirming our own practice.

"Owing to different climatic conditions, the portable house system so largely used in the United Kingdom is most suited to farm operations in this country [Great Britain], and should be maintained where poultry are a part of the ordinary stock of the farm. . . .

"American experience confirms our own as to the profitable nature of duck farming as a special business on a large scale. . . .

"The importance of a thorough training, theoretical and practical, in poultry keeping is more fully recognized in America than with us, but the instruction is specialized and not so general, and facilities for instruction are eagerly sought for by those intending to take up this work.

"The experiment stations in America are most complete, well maintained and equipped, and by co-ordination considerable results have been achieved, which example should without delay be followed in Britain."

Poultry in Pennsylvania, T. E. ORR (*Penn. Dept. Agr. Bul. 143, pp. 36, pls. 3, fig. 1*).—On the basis of personal experience the author discusses the feeding and care of poultry, artificial incubation, the raising of ducks, turkeys, and geese on the farm, poultry diseases, and related questions.

A combination of fruit growing and poultry raising is especially recommended. "Locate your poultry houses if possible so that the runs will be in an orchard. The fowls will destroy thousands of harmful insects, thus greatly benefiting the trees and increasing the prospects for fruit, and the fowls will gain great comfort and benefit by the protecting shade of the trees. Plum trees and cherry trees are especially benefited by the presence of the fowls about their roots. Peach trees will grow most rapidly and soonest give an abundant shade."

Poultry notes; guinea fowls; bananas for chickens (*Jour. Jamaica Agr. Soc., 10 (1906), No. 8, pp. 308, 309*).—Brief notes are given regarding raising guinea fowls or "Jamaica pheasants" and other poultry under local conditions. Ripe bananas are recommended as a good morning food for fowls, but boiled green bananas are not regarded as conducive to egg production.

Poultry notes. Bananas as feed (*Jour. Jamaica Agr. Soc., 10 (1906), No.*

10, pp. 401, 402).—Brief statements are made regarding the use of local feeding stuffs for poultry. Bran with boiled green bananas or ripe bananas and some green corn are among some of the mixtures suggested as suitable for use in morning rations.

Regulating the egg trade, K. BORCHMANN (*Ztschr. Fleisch u. Milchhyg.*, 17 (1906), No. 1, pp. 3-11).—The defects in the present system of marketing eggs in Berlin are pointed out and reforms suggested.

DAIRY FARMING—DAIRYING—AGROTECHNY.

A comparison of alfalfa meal and wheat bran for dairy cows, T. I. MAIRS (*Pennsylvania Sta. Bul.*, 80, pp. 10).—Alfalfa meal or finely ground alfalfa hay was compared with wheat bran, pound for pound. The test was made with 10 cows divided into two equal lots. The feeding covered 4 periods of 3 weeks each. The wheat bran was fed to both lots during the first and fourth periods, to lot 2 during the second period, and to lot 1 during the third period. The alfalfa meal was fed to lot 1 during the second period and to lot 2 during the third period. All other conditions were uniform for both lots.

The protein content of the alfalfa meal was 15.48 per cent and of the wheat bran 16.95 per cent. The alfalfa meal was eaten less readily than the wheat bran and produced a decrease in the yield of milk. With alfalfa meal at \$23 per ton and wheat bran at \$20 per ton, the prices prevailing in central Pennsylvania, the cost of grain for 100 lbs. of milk when the cows were fed alfalfa meal was 47.1 cts. and when fed wheat bran 45.3 cts. With wheat bran at \$20 per ton the alfalfa meal was apparently worth only \$21.28 per ton.

At present market price, the author, therefore, does not recommend alfalfa meal as a substitute for wheat bran as a feed for dairy cows.

Investigations on the effect of nutritive and condimental substances upon milk secretion, F. MERKEL (*Inaug. Diss., Leipzig, 1906; abs. in Milchw. Zeitsch.*, 2 (1906), No. 11, pp. 495-500).—In experiments with 15 cows the feeding of an excessively rich ration immediately after calving not only failed to increase milk production but tended to lessen it. The live weight of the animal, however, was favorably affected. When the same ration was fed later during the lactation period milk secretion was increased.

Fennel as a condimental or stimulating substance exerted a favorable influence on milk secretion only when given with heavy rations. Under such conditions, however, there was a decrease in the live weight of the animal.

Comparative experiments on the feeding value of sugar and proteids for the production of milk and milk fat, E. A. BOGDANOV (*Izv. Moscov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscow)*, 12 (1906), No. 3, pp. 257-307).—This work is a direct continuation of that previously noted (E. S. R., 17, p. 71). Four experiments were conducted each including 4 cows and continuing for 3 or 4 periods of 10 days each. The general conclusion drawn is that the feeding of sugar is without particular value. In individual instances, however, sugar increased milk production. It was only in the case of rich rations with a narrow nutritive ratio that the feeding of sugar was economical and it was thought that here the same results might have been secured with a much cheaper material.

Seasonal variations in the composition of cows' milk, H. C. SHERMAN (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 12, pp. 1719-1723).—Average monthly analyses are given of the milk of a herd of about 600 cows in Westchester County, New York. Five years' results are summarized and compared with similar data reported by H. D. Richmond. The cows were either registered or

grade Jerseys and were selected and managed with a view to the production of milk rich in fat. The following table gives the average composition of the afternoon milk from September, 1900, to August, 1905:

Average composition of cow's milk by month.

Month.	Fat.	Solids-not-fat.	Protein.	Milk sugar.	Ash.	Total solids.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
January.....	5.57	9.27	3.80	4.82	0.76	14.91
February.....	5.52	9.39	3.77	4.86	.76	14.91
March.....	5.46	9.27	3.66	4.86	.75	14.73
April.....	5.42	9.18	3.60	4.84	.74	14.60
May.....	5.40	9.17	3.57	4.86	.74	14.57
June.....	5.53	9.11	3.57	4.79	.75	14.64
July.....	5.24	8.96	3.49	4.73	.74	14.20
August.....	5.26	9.02	3.53	4.71	.74	14.28
September.....	5.33	9.15	3.62	4.79	.74	14.48
October.....	5.36	9.26	3.70	4.81	.75	14.62
November.....	5.38	9.35	3.80	4.81	.75	14.73
December.....	5.52	9.43	3.85	4.82	.76	14.95
Average.....	5.42	9.22	3.66	4.81	.75	14.64

As compared with the data obtained by Richmond in England, the author's results show in general similar seasonal variations in fat and solids-not-fat. The fat, however, varied less in proportion to the amount present and reached a maximum somewhat later in the winter, while the solids-not-fat varied more and reached a maximum about a month earlier.

Daily variations in milk, M. SIEGFELD (*Molk. Ztg.*, 20 (1906), No. 1/4, pp. 1239-1241).—This gives the results of analyses of the milk of 8 herds during 1 year. The highest and lowest fat content for each herd during the year was as follows: 1, 3.80 and 2.15 per cent; 2, 4.75 and 2.20 per cent; 3, 4.30 and 2.75 per cent; 4, 4.75 and 2.25 per cent; 5, 4.50 and 2.55 per cent; 6, 4.00 and 2.70 per cent; 7, 5.05 and 2.50 per cent; and 8, 4.15 and 2.60 per cent. The causes of variation are discussed.

Fat content of ass's milk, WAGNER (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 12 (1906), No. 11, pp. 658, 659).—During the period from 1902 to 1906 analyses were made of 392 samples, the results showing a range in fat content from 0 to 0.7 per cent with an average of 0.125 per cent.

Comparative study of the more important lactoses, G. BONAMARTINI (*Rev. Gén. Lait*, 6 (1906), No. 1, pp. 10-18).—Preparations of lactose were made from the milk of the cow, ass, goat, and sheep, and also from human milk, and compared as regards water of crystallization, reducing power, polarization, and form of crystals. These means failed to show any difference in the preparations from the different sources.

Leucocyte content of milk drawn from apparently healthy animals, H. L. RUSSELL and C. HOFFMAN (*Jour. Amer. Med. Assoc.*, 17 (1906), No. 25, p. 2110).—This is a brief abstract of a paper presented before the thirty-fourth annual meeting of the American Public Health Association held in Mexico City, Mexico, December 3-7, 1906.

According to the authors, sufficient data have not yet been secured on the leucocyte content of milk to warrant the formulation of a scientific standard for judging milk as to the presence of pus. They find wide variations in the leucocyte content of milk from cows having no discoverable udder lesion nor previous history of garget. The number is often in excess of present standards. The authors also find that a leucocytosis in animals subjected to changes in environment may manifest itself in the leucocyte content of the milk.

A milk epidemic of diphtheria associated with an udder disease of cows, A. ASHEY (*Pub. Health* [London], 19 (1906), No. 3, pp. 145-160, figs. 6).—Investigations of a severe epidemic of diphtheria in the villages of Twyford and Ruscombe in Berkshire in 1904 indicated that the disease was spread by milk and that this became infected from ulcers on the teats of cows.

Report on an investigation of an outbreak of typhoid fever at Kenton, Ohio, E. G. HORTON (*Ohio Sanit. Bul.*, 10 (1906), No. 7-12, pp. 142-148).—The data secured indicated that the outbreak was due mainly to infected milk.

The National Creamery Buttermakers' Association, 1906 (*Nat. Cream. Buttermakers' Assoc. Rpt.*, 1906, pp. 227, figs. 2).—This contains a number of addresses on subjects such as the preparation and value of starters, pasteurization of cream for butter making, the creamery overrun, churning of fresh cream, etc., with a discussion following each paper.

In addition to the proceedings of the National Creamery Buttermakers' Association this report includes an account of the national dairy farmers' convention which was held about the same time. Some of the subjects discussed at the latter meeting were science and profit in dairying, the breeding and handling of dairy cows, economical feeding for milk production, profitable dairy farming, the hand separator problem, and the milk and cream exhibit at the national dairy show.

The preparation of dry cultures, A. VON ADELLOFF (*Milchz. Zentbl.*, 2 (1906), No. 11, pp. 489-492). Tests were made of magnesia, gypsum, milk sugar, and potato flour for absorbing milk cultures of lactic-acid bacteria for use in butter making. A culture was also prepared by liquefying a gelatin culture of lactic-acid bacteria by heating to 40° C., adding milk sugar, drying the mixture, and pulverizing.

The gypsum, magnesia, and potato flour were considered unsuitable for this purpose. The author believes that a dry culture should be prepared from a milk culture, and that the absorbent material should be soluble and indifferent in character.

Improving the keeping qualities of butter by means of hydrogen peroxid, A. HESSEGÜSTROW (*Milchz. Zentbl.*, 2 (1906), No. 11, pp. 487-489).—Butter was made from cream which had been treated with hydrogen peroxid according to the method of Budde. The results of the three tests made indicated that this method improved the keeping quality of the butter. The author, however, does not wish to draw positive conclusions from such limited data.

Contribution to the knowledge of casein and coagulation with rennet, S. SCHMIDT-NIELSEN (*Upsala Läkareförs. Förhandl.*, n. ser., 11 (1906), Sup. pp. 26).—According to the experimental results obtained, pure neutral sodium caseinate and sodium paracaseinate in 2 per cent solutions are not precipitated by pure sodium chlorid, but are completely precipitated by common salt which contains 0.4 per cent of calcium. The quantity of calcium required for this precipitation is for the casein 6.5 per cent and for the paracasein 3 per cent. This is, however, in excess of the amounts actually combining with the casein and paracasein. The calcium may be replaced by barium or magnesium in quantities three times as large.

It was found that the formation of so-called whey albumin stands in close relation to the formation of paracasein, though it is not yet clear in what way the albumin is formed. In addition to the enzym bringing about the changes resulting in paracasein and whey albumin, it is possible that there is also present in the rennet solution a second proteolytic enzym.

Milk or calcium casein solution decidedly alkaline to litmus is coagulated with rennet. During coagulation the reaction tends to become acid. It is

considered clear that coagulation with rennet can take place in the absence of free H ions. The number of OH ions present, however, must not be so great as to give a reaction with phenolphthalein.

The ripening of Edam cheese, F. W. J. BOEKHOUD and J. J. OTT DE VRIES (*Rec. Gén. Lait*, 6 (1906), No. 1, pp. 1-10).—According to the results of the present and earlier investigations (E. S. R., 17, p. 589) lactic-acid bacteria develop rapidly in fresh Edam cheese and destroy all the lactose. These organisms then become latent and other bacteria develop. The changes thus produced are not believed to be the sole cause of the odor and taste of this cheese.

During milking and subsequent handling milk becomes greatly contaminated with bacteria, among which are many liquefying forms. These are unable to subsist in the acid medium resulting from the lactic fermentation in the cheese, but it is argued that the proteolytic enzymes previously produced by the liquefying bacteria remain unchanged and bring about changes in the cheese resulting in the formation of the characteristic odor and taste. Lactic-acid bacteria and proteolytic enzymes are therefore considered the ripening agents.

Contribution to the bacterial flora of Edam cheese, J. RAAMOT (*Dissertation, Königsberg, 1906; abs. in Milchw. Zentbl.*, 2 (1906), No. 11, pp. 509, 510).—Bacteriological examinations were made of various grades of Edam cheese. The better the cheese the more lactic-acid bacteria were found. The conclusion is therefore drawn that lactic-acid bacteria are the most important agents in the ripening of this cheese.

Fermentation organisms, A. KLÖCKER (*Die Gärungsorganismen in der Theorie und Praxis der Alkoholgärungsgewerbe. Stuttgart: Max Waag, 1906, 2. ed., pp. XVI+392, figs. 157*).—An English translation of the first edition of this treatise was noted in E. S. R., 15, p. 450.

Annual report on fermentative organisms, A. KOCH (*Jahresber. Gärungsorganismen*, 13 (1902), pp. VIII+672).—This report for 1902 recently published contains abstracts and titles of articles relating to the different fermentations classified under (1) text-books and reviews, (2) methods and apparatus, (3) morphology, bacteria, and yeasts, (4) general physiology of bacteria, (5) special fermentations, and (6) enzymes.

Technology of fats and oils, G. HEFTER (*Technologie der Fette und Öle. Berlin: J. Springer, 1906, pp. XVII+741, pls. 10, figs. 346*).—This is the first part of a handbook on the production and utilization of fats, oils, and waxes of vegetable and animal origin.

VETERINARY MEDICINE.

Text-book of comparative general pathology, T. KITT, trans. by W. W. CABBURY (*Chicago: W. T. Keener & Co., 1906, pp. XIII+471, pls. 4, figs. 131*).—The veterinary literature in the English language has been in need of a general text-book of pathology treated from the veterinary standpoint rather than from that of human medicine. The translation makes this work available to veterinary students in America and England, and must, therefore, be of considerable influence in furthering the present tendency toward the improvement of veterinary education.

The text contains a discussion of the history of pathology, predisposition toward disease, congenital and hereditary disease, and the causes of disease together with a thorough account of pathological processes as observed in disturbances of the circulation, metabolism, and the progress of infectious diseases.

A number of new illustrations have been added to the text to show various features of microscopical pathology.

While the general pathological processes are very similar in man and animals the appearance of the lesions may differ considerably in different animals and the discussion of these matters can, therefore, be much more specific in a text-book of this sort than one which attempts to include human as well as animal pathology.

Report of the Minnesota State Live Stock Sanitary Board, 1906, S. H. WARD ET AL. (*Ann. Rpt. Minn. Live Stock Sanit. Bd.*, 3 (1906), pp. 108).—During the year under report 13,707 cattle were tested and 1,438 were killed as tuberculous. This is equal to 10 per cent, but it is believed that the percentage would not be so high if all of the animals of the State were tested. Similarly during the year 3,322 horses were tested with mallein and of this number 606 reacted and were killed. An indemnity is paid to the owners for animals killed by the State authorities.

It is stated that more stringent milk and meat inspection laws are required for the proper regulation of traffic in these food materials in the State. Of the cattle imported into Minnesota from other States nearly 4 per cent were found to be tuberculous and were condemned. It is also noted that tuberculosis is becoming more frequent in hogs.

Detailed reports were made on the laboratory work undertaken by the State board on mange, necrotic stomatitis, rabies, hemorrhagic septicemia, swamp fever, and dourine.

Division of animal industry, V. A. NORGAARD (*Rpt. Bd. Comrs. Agr. and Forestry Hawaii*, 2 (1905), pp. 167-228).—Glanders prevails to a great extent in Honolulu and vicinity and the mallein test has been generally applied for controlling it. The spread of the disease is partly due to the use of public watering troughs for glanderous horses.

It has been observed in Hawaii that the horn fly attacks scabby sheep, causing serious irritation of the scabby areas and sometimes annoying the sheep by attacking other parts of the body not heavily covered with wool. It is possible that the horn fly may carry sheep scab.

Copies are included of the rules promulgated by the governor and board of commissioners regarding animal industry in Hawaii. Considerable attention has been given to the improvement of animal industry in the islands and to a study of the conditions which have led to failure in certain instances. It is suggested that the soils and forage plants of Hawaii are somewhat lacking in lime, and lime or bone meal is, therefore, recommended as an addition to the rations. Osteomalacia has been observed quite frequently and appears to be due to the absence of lime.

Report of the cattle sanitary board of New Mexico, 1904-5, W. C. BARNES (*Ann. Rpts. Cattle Sanit. Bd. N. Mex.*, 1904-5, pp. 30).—Considerable work has been done in dipping cattle for the control of mange and the destruction of cattle ticks. The results from this work are promising. Statistical information is furnished regarding the health of domestic animals and the shipment of cattle, horses, mules, and hides.

Report of the veterinary director general, J. G. RUTHERFORD (*Rpt. Vet. Dir. Canada, 1905, pp. 232, pls. 12*).—This report covers a period from November 1, 1904, to March 31, 1906, and is largely occupied with a discussion of tuberculosis, glanders, dourine, cattle mange, rabies, hepatic cirrhosis, and meat inspection.

Hog cholera is practically under control in the regions where it prevails. According to reports received by various inspectors, glanders exists to a serious extent in most parts of the Dominion. The present system of killing all

animals affected with the disease whether they show clinical symptoms or not will probably reduce the extent of glanders.

An extensive series of feeding experiments was carried on in Antigonish during which it was clearly shown that Picton cattle disease or hepatic cirrhosis is caused by eating *Scaccia jacobae*. Before this fact was demonstrated, the disease was considered infectious and an indemnity was paid to the owners of condemned animals.

A number of outbreaks of rabies took place and required the attention of the veterinary officers. Notes are also given in the reports of the numerous inspectors from different parts of the Dominion on the health of animals in their localities and the prevalence of common diseases.

Report of the veterinary service in the Kingdom of Saxony for 1905 (*Ber. Veterinärw. Königr. Sachsen, 50 (1905), pp. 419*).—As is customary in these reports the organization of the veterinary service is given, followed by an elaborate account of the general status of the health of animals and special reports on diseases, medicines, dietetics, cases of poisoning, the live-stock industry, veterinary police work, cattle breeding, and goat raising.

Statistical data are presented on the number and distribution of inspectors and freibanks in the Kingdom of Saxony, the number of animals slaughtered and inspected during the year, and the cause of condemnation of inspected animals.

The organization and function of the police and veterinary service in the kingdom (*Organizzazione e Funzionamento dei Servizi di Vigilanza e Assistenza Zoiatrica nel Regno. Rome: Min. Int., 1906, pp. 302*).—In the present report a general discussion is presented of the principles which lie at the foundation of veterinary police and similar control work in the prevention of the spread of animal diseases. Such veterinary work may be organized under government supervision or may be of a communal or cooperative nature. Extensive tables are given showing the imports and exports in animal products from 1902 to 1905.

The larger part of the volume is occupied with a discussion of the present status of the important animal diseases in Italy, including foot-and-mouth disease, infectious swine diseases, anthrax, blackleg, glanders, contagious agalactia, rabies, tuberculosis, etc.

Report of proceedings under the diseases of animals acts for the year 1905 (*Dept. Agr. and Tech. Instr. Ireland, Rpt. Diseases Anim., 1905, pp. 112, pls. 3*).—A brief summary is presented of the present status of legislation regarding contagious diseases in Ireland with especial reference to anthrax, sheep scab, hog cholera, glanders, parasitic mange, and epizootic lymphangitis. A detailed report is given by M. Hedley on hog cholera and other serious animal diseases in Ireland, and by D. S. Prentice on the transportation of animals. On the whole, hog cholera has diminished greatly in prevalence during the past few years; rabies was not observed during 1905; glanders presented no serious problems; and parasitic mange occurred in 169 outbreaks. Copies are given of all orders and circulars which have been issued regarding the control of animal diseases in Ireland.

Report of the veterinary surgeon to the corporation of the city of Glasgow for 1904-5, A. M. TROTTER (*Rpt. Vet. Surg. Glasgow, 1904-5, pp. 41*).—The present detective system of inspecting meat in Glasgow has certain disadvantages and is not effective in preventing unsuitable meat from coming into the market. The meat inspector's time is too much occupied in this system in running about from place to place inspecting a few carcasses which may be delivered by farmers or dealers to butchers, or even directly to consumers. A

change of plan is recommended, since the author believes that a preventive system would be more effective in securing the inspection of all meat at the point of production, and would save the time of the meat inspector for more important work.

The results of meat inspection in Glasgow for the years 1904-5 are presented in a tabular form. Particular attention is given to tuberculosis, anthrax, and the inspection of milch cows.

Veterinary service and meat inspection for 1904 (*Norges Off. Statist.*, 5, ser., 1904, No. 15, pp. VIII+287).—As in previous years the present report on veterinary service and meat inspection in Norway contains a general account of the health of animals in various parts of Norway with particular reference to the appearance and distribution of anthrax, catarrhal fever, blackleg, swine erysipelas, tuberculosis, abortion, and milk fever. The distribution of these diseases in different parts of the country is shown in a series of tables.

Copies are given of the meat inspection regulations which are at present in force in Norway.

The epitome of cattle inspectors' returns (*Rhodesian Agr. Jour.*, 3 (1906), No. 6, pp. 636-642, pl. 1).—In these returns particular attention is given to an account of the conditions in various parts of Rhodesia with reference to rabies, contagious abortion, glanders, African coast fever, and horse sickness.

Results obtained in the field of cattle diseases, F. MARKIEL (*Tierärztl. Zentbl.*, 29 (1906), No. 28, pp. 444-454).—This article contains a brief summary of recent veterinary investigation and the results obtained in the control of sterility, metritis, mammitis, and actinomycosis.

Prophylaxis of contagious diseases of cattle, J. LIGNIÈRES (*Bol. Min. Agr.* [Buenos Ayres], 5 (1906), No. 3, pp. 363-383, figs. 12).—A brief statement is made of results obtained by the use of vaccine in controlling anthrax, blackleg, and Texas fever. Directions are also given for the destruction of rats and for the use of tuberculin and mallein.

Notifiable diseases under the milk and dairy supervision act, 1905, S. S. CAMERON (*Jour. Dept. Agr. Victoria*, 4 (1906), No. 8, pp. 481-489, figs. 2).—A discussion is presented of the symptoms and means of preventing accidental and contagious abortion and contagious mammitis in cows. For contagious abortion, the author recommends the use of antiseptic washes containing carbolic acid, creolin, lysol, or corrosive sublimate. The best results in the treatment of contagious mammitis were obtained from the injection of a solution of boracic acid at the rate of 1 part to 20 parts of warm water.

Tuberculous infection and the resistance of the organism to the disease, A. CALMETTE (*Rev. Hyg. et Pol. Sanit.*, 28 (1906), No. 8, pp. 641-660).—The author admits the existence of three specifically different forms of tubercle bacilli in cold-blooded animals, birds, and mammals, respectively. The morphological differences, however, do not preclude the transference of these bacteria from one group of animals to another.

The conclusion is reached as a result of the study of this problem that animals and man are usually infected with tuberculosis through the alimentary tract. The necessity of a sanitary control of the milk supply is strongly urged.

Tubercle bacilli of different origin, M. RABINOWITSCH (*Ztschr. Tuberkulose*, 9 (1906), Nos. 5, pp. 457-501; 6, pp. 546-584).—As a result of numerous cultures and inoculation experiments, the author comes to the conclusion that the biological characters of the tubercle bacillus of cold-blooded animals depend entirely upon adaptation to specific conditions. The organism may be made to produce the typical growth of the mammalian tubercle bacillus by passage through the

body of the mammal or exceptionally this occurs spontaneously. Similarly the mammalian tubercle bacillus may be made to develop the growth of the bacillus of cold-blooded animals by inoculation of the latter. These two forms of the tubercle bacilli are capable of producing typical tuberculous lesions in either warm or cold-blooded animals. It is concluded, therefore, that the tubercle bacilli of men, cattle, birds, and cold-blooded animals are merely vegetative modifications of one and the same species.

Milk and tuberculosis, J. W. BRITTLEBANK (*Vet. Rec.*, 19 (1906), No. 949, pp. 164, 165).—In an examination of 10,527 cows kept in city stables only one animal was found to be affected with tuberculosis of the udder. During the same investigation of the milk supply of Manchester, England, 764 samples were taken from milk delivered by 565 different farmers from different counties and in these samples the percentage of tuberculous milk varied from 3 to 12.

Infectious abortion in cattle, B. BANG (*Jour. Compar. Path. and Ther.*, 19 (1906), No. 3, pp. 191-202).—It is now 10 years since the author elucidated the etiology of this disease. In the meantime much work has been done along the line of prevention. The author believes that where the nature of the disease is understood the farmer may readily protect his herd against it by proper sanitary precautions.

During the past 3 years the author has carried on experiments in attempting to immunize cows, sheep, and goats against the disease. It has been observed that aborting cows acquire a certain degree of immunity. In this work intravenous injections of serum bouillon cultures of the micro-organism of abortion were adopted. In some cases this treatment produced abscesses and other symptoms of reaction, but considerable immunity resulted, and the author hopes that this method of vaccination will ultimately give a means of controlling the disease.

Immunization toward anthrax, F. MURILLO (*Ztschr. Hyg. u. Infectiouskrankh.*, 54 (1906), No. 2, pp. 178-188).—It has often been observed that there may be more or less antagonism between different bacteria or higher plants which are growing in the same medium. The author tested the effect of diphtheria toxin in the attenuation of anthrax cultures. Cultures thus obtained were tested on experimental animals with results which indicate that this method is quite successful in producing immunity.

The author claims certain advantages for this method over the Pasteur system. According to the latter method a temperature of 42° C. is recommended for the attenuation of the anthrax vaccine. By the author's method any temperature up to 37° is satisfactory. It was also found that it is not necessary to use the cultures on a certain day, but that they remain suitable for a number of days after treatment. By combining cultures and toxins in different proportions in ordinary bouillon it is possible to obtain a wide series of gradations in the vaccine.

Anthrax in frogs, F. DITTHORN (*Arch. Hyg.*, 57 (1906), No. 4, pp. 313-322).—In inoculation experiments with frogs, the author shows that anthrax bacilli in passing through the body of these cold-blooded animals are not attenuated but remain in condition to affect higher animals and produce an acute form of the disease. In making experiments of this sort it is necessary to observe closely the temperature condition surrounding experimental frogs since frogs are very susceptible to sudden temperature changes.

Prevention of blackleg by the use of the Pasteur blacklegine, H. BIBBEY (*Vet. Rec.*, 19 (1906), No. 950, pp. 168, 169).—In the use of this vaccine the author makes the inoculation at the root of the tail, which is afterwards washed

with carbolic soap. On the fourth day after inoculation the animals are inspected to see if any abscesses are formed at the point of inoculation. Little or no trouble is ordinarily experienced from the use of this method.

Rinderpest in Egypt, S. ARLOING (*Ann. Soc. Agr. Sci. et Indus. Lyon*, 1905, pp. 347-369).—The conditions observed in outbreaks of rinderpest in Egypt are outlined in considerable detail with notes on the losses caused by the disease, the symptoms observed, and measures taken for controlling the outbreaks. A number of inoculation methods have been tested, usually in combination with the ordinary methods of police sanitation, such as the destruction of infected animals, isolation of exposed animals, and disinfection of premises.

While serum inoculation has admittedly given good results in preventing the spread of rinderpest, the author believes that the successful control of the disease in all cases where serum has been used is to be partly ascribed to the simultaneous application of strict police sanitation. In the future control of rinderpest, the author recommends the destruction of diseased animals and strict quarantine as of prime importance.

Piroplasmoses in Dutch East Indies, C. A. PENNING (*Veercartsenijk. Bl. Nederland. Indië*, 18 (1906), No. 1-2, pp. 102-108, pl. 1).—Both Texas fever and Rhodesian or coast fever occur among cattle in Java. According to statistics collected by the author, cattle become infected with one or both of these diseases at a young age, and about 10 to 15 per cent die before they are a year old. Those which recover possess a lasting immunity to Texas fever and coast fever. It has been observed that cattle which are imported to Java from South Australia become affected with one or the other of these diseases, and the majority of them die within a year after their importation. Notes are given on the symptoms of Texas fever and African coast fever and on the blood parasites observed in cases of these diseases.

Piroplasmosis in cattle (*Svensk Vet. Tidskr.*, 11 (1906), No. 9, pp. 411-413, pls. 2).—An outbreak of piroplasmosis closely resembling Texas fever in its general symptoms and lesions occurred among cattle in Sweden, and the disease was investigated by the author. The blood corpuscles seemed to be destroyed, as in the case of Texas fever, so that one of the symptoms in most cases was bloody urine. The cattle were infested with 2 species of ticks, which were identified as *Ixodes ricinus* and *I. hexagonus*.

Scab ordinance, 1903, and the amending scab ordinances, 1905-6 (*Bloemfontein, Orange River Colony: Dept. Agr., 1906, pp. 19*).—Copies are given of the ordinances now in force in the Orange River Colony for the eradication of sheep scab within the colony.

Protective vaccination against braxy, JENSEN (*Berlin. Tierärztl. Wchnschr.*, 1906, No. 41, pp. 743, 744).—Three methods have been used in producing immunity to braxy. In the first, a virulent pure culture is mixed with equal parts of bouillon and horse serum and kept at a body temperature for a week before using. The second method consists in the use of a serum obtained from horses after inoculating them with virulent cultures. The author has most confidence in the success of a third method, which consists in placing threads in a culture which is treated with hydrogen until spore formation takes place, after which the threads are introduced into a fold in the skin of the animal to be immunized.

Swine plague and hog cholera, E. JOEST (*Schweinesuche und Schweinepest. Jena: Gustav Fischer, 1906, pp. VIII + 280, pls. 6, figs. 22*).—The present account is of a monographic nature and attempts to present a thorough discussion of the results thus far arrived at by a study of swine plague and hog cholera, and also a statement of the more important problems still remaining to be solved in connection with these diseases. The literature of the subject

is critically discussed in connection with a bibliography including publications down to the end of 1905. A special feature of the work is a discussion of the veterinary police measures adopted in controlling these diseases in various countries of Europe and in the United States. Mention is also made of the contention of W. Grips that *Bacillus suiscepticus* is not the cause of swine plague.

The discussions of both swine plague and hog cholera are arranged along the same line and include the etiology, pathology, and methods of infection and control of the disease. Furthermore, an account is given of the problems of mixed infection and differential diagnosis between swine plague and hog cholera and methods of immunization to these diseases.

Hog cholera, E. LECLAINCHE (*Rev. Gén. Méd. Vét.*, 8 (1906), No. 92, pp. 417-423).—The author calls attention to the fact that in the early history of the study of this disease it was supposed to include two forms caused by two specifically distinct bacteria. At present swine plague and hog cholera are considered distinct by all investigators, and recently the demonstration of another form of hog cholera not due to any known micro-organism has complicated the problem so that further investigation is necessary.

Bacillus pyocyaneus as a cause of rhinitis and hemorrhagic meningitis in hogs, F. KOSKE (*Arb. K. Gsundtsamt.*, 23 (1906), No. 2, pp. 542-553).—Young pigs are frequently affected with a disease resembling smulles in sheep. According to the author's investigations *Bacillus pyocyaneus* may be found in such cases, and in inoculation experiments it was determined that this organism is pathogenic for young pigs and may produce the disease.

The horse; its treatment in health and disease, J. W. AXE (*London: Gresham Pub. Co., 1906, vols. 1, pp. XVIII+1-164, pls. 20, figs. 73, charts 9; 2, pp. X+165-344, pls. 16, figs. 69, charts 4; 3, pp. X+345-512, pls. 13, figs. 65; 4, pp. XII+1-160, pls. 9, figs. 64*).—In preparing this work on the horse the editor has secured the assistance of a number of experts to prepare different technical parts. The work as a whole is intended to contain such information as may be needed by horsemen with regard to the breeding, care, and treatment of the horse.

The anatomy of the horse is described with particular reference to its bearing on health and disease. The same may be said with regard to the physiological discussion. The larger part of the work is occupied with a detailed account of the diseases commonly known to affect the horse. The illustrations serve to show the best types of horses, various points in the conformation of the horse, positions assumed in different diseases, and numerous pathological details. A dissectible plate accompanies the work showing the details of the internal and external anatomy.

Veterinary and biological studies on horse production in Württemberg, H. SOHNLE (*Hippologische, veterinärmedizinische und biologische Beiträge zur württembergischen Pferdezucht*, Pflüningen: F. Find, 1906, pp. 105).—The author maintains on the basis of his observations that races of the horse or other animals once established in a given locality can not be reproduced in exactly the same form in other localities. Where a given race of the horse appears to be desirable for importation into some other locality it is necessary to import at relatively frequent intervals pure-bred sires from the native locality in order to keep up the form of the race.

Notes are given on a number of common diseases among horses, including azoturia, ophthalmia, arthritis, etc.

Special report on glanders, J. G. RUTHERFORD (*Canad. Dept. Agr., Health of Animals Branch, 1906, pp. 24*).—The essential features of this report were

presented before the New Haven meeting of the Veterinary Medical Association and have been previously noted (E. S. R., 18, p. 99).

Experimental glanders in guinea pigs, M. NICOLLE (*Ann. Inst. Pasteur*, 20 (1906), Nos. 8, pp. 625-664; 9, pp. 698-730; 10, pp. 801-837).—The symptoms and course of glanders in guinea pigs are described in detail and are compared with those of pseudo-tuberculosis and also with the symptoms which appear in rabbits and other animals when infected with glanders. The supersensitiveness to the glanders bacillus sometimes observed in guinea pigs appears to depend upon the condition of the animal, the previous treatment which it has received, and the virulence of the glanders bacillus used in the experiments.

The author has shown that it is possible to immunize guinea pigs to glanders. There are three methods by which this may be accomplished—by repeated injections of small doses of dead glanders bacilli, of living bacilli in minute quantities, or by a single dose of living bacilli in such quantities as barely to produce an infection.

Recurrent mange, F. SMITH (*Vet. Rec.*, 19 (1906), No. 953, pp. 215, 216).—The author refers to the difficulties usually experienced in bringing about a complete cure of mange in horses. Most of so-called cases of recurrent mange are due to the fact that the supposed cure in the first instance was only apparent.

Infectious scratches and verminous aneurism, H. WUCHERER (*Wchuschr. Tierheilk. u. Viehzucht*, 50 (1906), No. 35, pp. 681-685).—In a number of young horses the author observed the prevalence of an infectious form of scratches. At first the appetite failed, the flanks became tucked up, and a slight elevation of temperature was observed. After 3 or 4 days phlegmonous swellings appeared about the crown of the hoof and fetlock, followed by an exudation from these points. As a rule, the animals showed marked improvement after about 1 week, but in some cases the disease was much more refractory even after thorough application of disinfectant powders.

Notes are also given on cases of verminous aneurism due to emboly and thrombosis of the anterior mesenteric artery.

The clinical symptoms of malaria in horses, L. BARUCHELLO (*Clin. Vet. [Milan]*, 29 (1906), No. 31, pp. 745-754).—According to the author's observations the fundamental symptoms of malaria in horses are fever, icterus, petechiæ, and hemoglobinuria. All of these symptoms are described in considerable detail and notes are given on means of diagnosing between malaria and other diseases with which it might be confused.

The pathology and treatment of pernicious anemia of the horse, J. N. RIES (*Rec. Méd. Vét.*, 83 (1906), No. 19, pp. 677-683).—The symptoms of this trouble are described in considerable detail. In many cases the author believes that the chief cause of the disease is excessive infestation with botflies and other parasites.

A case of spirillosis in the horse, R. J. STORBY (*Jour. Compar. Path. and Ther.*, 19 (1906), No. 3, pp. 226-228, figs. 2).—This disease in South Africa may be mistaken for dik-kop until after some experience is had. The animal becomes much emaciated and edematous swellings appear on various parts of the body. The most characteristic feature of the disease is the rapid emaciation.

Surra in Africa, L. CAZALBOU (*Rev. Gén. Méd. Vét.*, 8 (1906), No. 92, pp. 401-417, figs. 5).—The geographical distribution of surra in Africa is discussed with mention of the symptoms of the disease in camels and horses. Experimental tests proved the possibility of transmitting the disease by contact or by inoculation. A number of insects are commonly believed to be instrumental in transmitting the blood parasite, but it is not definitely known whether they are the only agents of transmission or not.

Trypanosomata and trypanosomiasis, E. N. TOBEY (*Jour. Med. Research*, 15 (1906), No. 1, pp. 117-175).—The present article is a summary of the results of investigation on trypanosomes and the diseases caused by them. The author gives an account of methods of cultivating trypanosomes and of the prevalence of various diseases caused by these organisms, such as surra, dourine, mal de caderas, etc.

Hemorrhagic septicemia in elephants, G. H. EVANS (*Jour. Trop. Vet. Sci.*, 1 (1906), No. 3, pp. 263-268).—Hemorrhagic septicemia appears to be of as frequent occurrence in elephants as is anthrax, and shows about the same symptoms as the latter disease. Infection appears to take place largely through skin wounds. Medicinal treatment is of little avail and nearly all cases end fatally. The author had no opportunity to test the serum treatment. The observations recorded in the paper are of importance as indicating another source of infection from this disease.

Lesions in the digestive tract of the horse due to the larvæ of botflies, WEINBERG (*Compt. Rend. Soc. Biol. [Paris]*, 61 (1906), No. 27, pp. 172, 173).—From a study of the lesions caused by botflies the author concludes that they cause inflammatory or other injuries to the stomach walls of infested horses without producing any bacterial infection. If, however, pathologic bacteria are present such infection may take place. The botflies are, therefore, to be considered in the same class with parasitic worms in so far as this matter is concerned.

The geographic distribution of *Distomum hepaticum*, A. SARTO (*Centbl. Bakl. [etc.]*, 1, Abl., Orig., 41 (1906), No. 8, p. 822).—According to various authors who have studied the common liver fluke, this parasite occurs in Europe, Egypt, India, Australia, and America. It has heretofore been doubtful whether the parasite is found in China, Korea, or Japan. The author made an investigation of this matter and found fluke worms in 16 $\frac{2}{3}$ per cent of the livers of cattle inspected at the abattoir in Okayama, Japan.

***Cysticercus cellulose* and its detection in living hogs**, J. VON KUKULJEVIĆ (*Berlin. Tierärztl. Wchenschr.*, 1906, No. 34, pp. 626-630, figs. 9).—A detailed description is given of a practical method of throving hogs and examining the tongue for the presence of mease worms. This method of examination is easily carried out, but it is recommended that the hogs be not fed on the morning of the examination since they endure the inspection better when the stomach is comparatively empty.

The literature relating to this subject is critically reviewed.

The occurrence of trichinæ among rats, L. BAHR (*Maanedskr. Dyrlæger*, 18 (1906), No. 4, pp. 136-139).—Rats have been examined in many countries for the purpose of determining the percentage of infestation with trichinæ. The literature on this subject is briefly referred to by the author, who carried on an investigation of this sort, during which 371 rats were examined. Of this number 19, or 5.12 per cent, were found to be infested with trichinæ.

The question of poisoning by artificial fertilizers, J. SCHNEIDER and G. STROU (*Deut. Tierärztl. Wchenschr.*, 14 (1906), Nos. 38, pp. 457-459; 39, pp. 469-471).—A series of feeding tests was undertaken chiefly with rabbits, sheep, and cattle, during which the experimental animals were fed superphosphate, Thomas slag, and kainit. The feeding periods ranged from 10 to 30 days and the amounts of the different fertilizers were graduated according to the size of the animal.

The conclusion reached from these feeding experiments is that, under ordinary conditions, neither domestic nor wild animals are likely to eat a sufficient quantity of the artificial fertilizers in question to produce poisonous effects.

Examination of the Western Australian poison plants, E. A. MANN (*Jour. Dept. Agr. West. Aust., 13 (1906), No. 6, pp. 486-490, pls. 2*).—A detailed chemical examination was made of *Oxylobium parviflorum*, for the purpose of determining the presence of any poisonous principles in this plant. The method used in making the analyses of the plant is described. An alkaloid was isolated in a pure state and has been called lobine. It is very unstable as compared with most alkaloids, but in many respects resembles cygnin.

In experiments to determine the physiological action of lobine it was found that 0.1 grain dissolved in water was sufficient to cause the death of a guinea pig within 5 minutes after hypodermic inoculation. Further experiments will be made in order to determine more accurately the symptoms and exact fatal dose of the alkaloid. From a few experiments carried out in the laboratory it appears that lobine is readily destroyed by permanganate of potash, and this drug appears therefore to be a suitable antidote.

The harmful character of grape foliage sprayed with Bordeaux mixture, ADE (*Wechschr. Tierheilk. u. Viehzucht, 50 (1906), No. 37, pp. 721-726*).—On account of the occurrence of cases in which cattle were poisoned or killed by eating grape leaves, an examination was made into the possible causes of such poisoning. It may be due to specific substances in grape leaves, to poisonous compounds produced by the presence of fungus diseases, to poisonous substances developing in parasitic fungi killed on the grape leaves as the result of spraying with Bordeaux mixture, or to the copper contained in the latter. There appears to be little ground for the supposition that the small amount of copper on grape leaves sprayed with Bordeaux mixture is sufficient to cause cases of poisoning which have been observed.

Gastritis in cattle as a result of eating grape leaves, OHLER (*Wechschr. Tierheilk. u. Viehzucht, 50 (1906), No. 33, pp. 641-643*).—In July and August of every year, when grape vines are pruned, it is customary to feed the leaves to cattle, and a considerable number of cases of gastritis have resulted. In some cases, cows with young calves at their side may transmit the poisonous properties of infected grape leaves in the milk to such an extent as to kill the calves. In the author's opinion, the trouble is at least partly due to the prevalence of the parasitic fungus *Peronospora viticola* on the leaves. Affected leaves decay rapidly and give out a striking and disagreeable odor.

Poisoning by horse-radish, D. FAIRBANK (*Vet. Rec., 19 (1906), No. 946, pp. 117, 118*).—Symptoms of poisoning appeared among Hereford cattle and closely resembled those of colic. Two of the animals died and a post-mortem examination, as well as a study of the condition under which the trouble arose, showed that these were cases of poisoning from eating too much horse-radish root.

Cirrhosis of the liver in stock in Cape Colony, produced by two species of Senecio (Senecio burchelli and S. latifolius), W. ROBERTSON (*Jour. Compar. Path. and Ther., 19 (1906), No. 2, pp. 97-110, figs. 5*).—It has been known for some time that *Senecio burchelli* causes a cirrhosis of the liver in live stock in South Africa. During an investigation of various cases of this disease the author found that *S. latifolius* might also cause the same disease with fatal results. Detailed notes are given of the symptoms and the post-mortem findings in these cases.

RURAL ENGINEERING.

Topography, C. MURET (*Topographic. Paris: J. B. Baillière & Sons, 1906, pp. 499, pls. 9, figs. 186*).—A treatise on the practice of surveying, with special reference to its application in modern agriculture. It includes six chapters

treating the following subdivisions of the subject: definitions, maps, and scales; description of instruments used for various purposes; testing and adjustment of instruments, allowable errors, etc.; methods of leveling; general use of instruments and methods of surveying; special applications; land subdivisions and establishment and verification of land titles.

The assessment of drainage districts, L. E. ASHBAUGH (*Chicago: Western Society of Engineers, 1906, pp. 14, figs. 2*).—A discussion of the methods of making assessments of land in drainage districts as governed by the principle that assessments must be proportionate to benefits received. Arithmetical examples are given showing how to distribute expenses over the various tracts of a drainage enterprise.

Cement drain pipe (*Musch. Ztg., 4 (1906), No. 16, p. 189, fig. 1*).—Cement drains are said to have certain advantages over the usual tile in that the latter are seldom round and become warped and bent in burning, while the former are clean and glazed on the interior and are of uniform size and shape. The desired porosity can be given the cement pipe by using a mixture by volume of one to eight. It is claimed that cement pipes are cheaper than the earthenware tile and that they show no deterioration in use.

A hand-operated machine is described by which cement pipe can be very conveniently made in lengths of 13 in., and of diameter from 1 to 9 in.

Artesian irrigation, W. R. FRY (*Agr. Gaz. N. S. Wales, 17 (1906), Nos. 6, pp. 581-588, figs. 6; 7, pp. 683-695, figs. 5; 8, pp. 780-789, figs. 4*).—The author discusses the possibility of irrigating portions of New South Wales by artesian water. While irrigation is not always necessary, the country frequently suffers from droughts, and in the absence of permanent streams, irrigation from artesian wells or by pumping from driven wells becomes a necessity.

The underground water, however, is saline in character, usually containing $41\frac{1}{2}$ grains of solid matter per gallon, most of which is sodium carbonate. After 7 years of irrigation with this water, an analysis of the soil as compared with virgin soil from the same locality shows no increase in the alkaline content, which probably "is due to the method of cultivation adopted." This consists in careful furrow irrigation, the aim being to get the water into the soil rather than on it. The soil in the locality where most experiments have been carried on contains 18 per cent of sand and 71 per cent of fine matter, chiefly clay. The crops successfully grown are the cereals, saltbush, sorghum, cowpeas, and melons. Orchards are also successfully irrigated.

Irrigation in the Transvaal, F. A. HURLEY (*Transvaal Agr. Jour., 4 (1906), No. 16, pp. 733-742*).—The writer discusses some of the practical aspects of the irrigation situation in the Transvaal and indicates some of the difficulties attendant upon the introduction of irrigation in that region. One of the chief of these is the present water law, which is based upon the primitive water laws of other countries, and under which it is impossible to secure a permanent water right. The water laws are at present under investigation by a commission. Other difficulties encountered are the physical features of the country, ignorance of hydrographic conditions, popular ignorance of the manner in which it is desirable to prepare estimates for irrigation schemes, labor, and transportation, the state of the markets, and lack of cooperation among farmers.

With regard to the government policy to be pursued, the author suggests a campaign of education in order to outline the manner in which the different districts are to be finally irrigated; then, if the law permits, the construction or encouragement of small schemes, or the construction of large schemes where future development may render them desirable.

The duty of water, A. McPHERSON (*Forestry and Irrig.*, 12 (1906), No. 9, pp. 417-421, pl. 1).—This article gives results of experiments made on the experimental farm of the Twin Falls (Idaho) Land and Water Company during 1906. It was found that the total amount applied on the farm was 26.10 in., which, deducting wastage and an assumed soil evaporation of 28.06 in. (based on evaporation from water surface), leaves 5.7 in. as the amount retained by the soil.

The flooding and furrow methods of irrigation are discussed and the conclusion reached that the furrow method is the more satisfactory.

Memorandum dated August, 1875, on the irrigation duty of water and the principles on which its increase depends, J. S. BERESFORD (*Punjab Irrig. Branch Papers*, No. 10, pp. 1-11).—Notes on the so-called efficiency of canals and a treatment of the nature and theory of absorption and percolation from which it is concluded that the total absorption loss varies as some function of the length of distributary. The theory is advanced, based on observed facts, that more waste of water by absorption occurs in excavated than in embanked channels. The seepage losses from the Ganges canal are said to be "capable of raising the springs over an area of 4,500 square miles to a height of 1.12 ft. in 12 months."

Note on irrigation duty of the Ban Doab Canal, dated April, 1883, R. G. KENNEDY (*Punjab Irrig. Branch Papers*, No. 10, pp. 12-25).—Data are given on the rate of absorption of water as determined by experiment on a flooded field of loamy soil, from which it was found that the absorption could be expressed by the equation $y=0.0891 x^{0.56}$ where y =depth of water over the surface absorbed and x =the number of days under water. The rate of absorption or loss by seepage in case of a canal was found to vary from 0.035 ft. in depth per hour over a gravelly open bottom to 0.0079 on the lower silted-up reaches of the canal, the surface upon which such measurements were based being the total area of water surface between given points.

Experiments on gauging the supply entering Rajbahas by means of the headgates (*Punjab Irrig. Branch Papers*, No. 8, pp. 20, pls. 2, figs. 4).—A series of papers giving the results of observations, the object of which was to determine the coefficient to be used in the usual submerged weir formula when applied in the measurement of water by ordinary lateral headgates. It was found that the coefficient varied somewhat with the pressure head and with the width of the gate. For a width of gate of 10 ft. the normal value of coefficient was found to be $C=0.79$. When the width was other than 10 ft. and not over 12 ft. the coefficient (0.79) is to be multiplied by a quantity

$$X=b \frac{(0.7201+.0074b)}{7.943}$$
 in which b is the width in feet. This modified coefficient may then be applied in the formula for a submerged weir $Q=C. b. h. 8.02 \sqrt{H}$, in which h =height of gate opening in feet; H =working head in feet or the difference between the depth in the canal and in the lateral measured above the sill of the gate, and Q =discharge in cubic feet per second.

Notched falls, A. G. REID (*Punjab Irrig. Branch Papers*, No. 2, pp. 18, figs. 3).—A description of measuring devices "consisting of a vertical wall extending across the channel and of a height above the upstream bed equal to the full supply depth in the upstream reach. In this wall one or more trapezoidal notches are cut from the crest downward through the whole height of the wall to the level of the upstream bed." The notches are of such size as will pass the entire maximum flow without causing the stream to back up. For the determination of flow through such a notch various formulæ are derived, taking into

account whether the notch has a free outfall, velocity of approach, etc., and examples are given illustrating their application.

Triennial revenue report of the public works department, irrigation branch, Bengal, for the three years ending 1904-1905 (*Trien. Rev. Rpt. Pub. Works Dept., Irrig. Branch, Bengal, 1904-5, pp. 94, diagrams 7*).—Statistics relating to the cost, operating expenses, and revenues of the canals of Bengal. Figures are also given of areas irrigated, crops grown, and duty of water on rice and other crops, together with items of interest on administration and control.

Silting operations (*Punjab Irrig. Branch Papers, No. 5, pp. 43, pls. 10, fig. 1*).—A description of methods of strengthening the banks of a canal when the bed is out of the soil or but little within it, chiefly by means of large subsidiary basins parallel to the canal through which all or a portion of the water of the canal is caused to flow, resulting in the deposition of silt in such basins up to the usual water level of the canal.

How horizontal runs affect the air lift, H. T. ABRAMS (*Municipal Engin., 31 (1906), No. 4, pp. 297, 298*).—A discussion of the results of experiments made by the writer upon a well operated by the air lift, where after leaving the well the water had to be conducted some distance by a horizontal pipe and then elevated into a reservoir. It was found that the horizontal run greatly impaired the action of the air lift and that it is much more economical under such conditions to raise the water by the air lift to a tank at the surface, after which the water may be forced by an air pressure or displacement pump through the horizontal run to the elevated tank.

Air-lift pumping, G. C. H. FRIEDRICH (*Compressed Air, 11 (1906), No. 6, pp. 4140, 4141*).—A discussion of this method of pumping and giving tables on submergence and efficiency; capacity and pipe sizes; and on the relation between lift, submergence, and air needed for air-lift pumping.

Tests of a new centrifugal pump (*Engin. Rec., 54 (1906), No. 13, pp. 352, 353, figs. 5*).—A report of tests made upon a 2-stage shrouded runner centrifugal pump of such design that it may readily be taken apart for inspection of the interior without disconnection of the suction or discharge pipes, or may be made into a simple pump or one of any number of stages by mere removal or addition of parts. In the form tested an efficiency of 77.79 per cent was shown at 600 revolutions per minute when delivering 3,255 gal. per minute at 100.7-ft. head.

On the uses of the centrifugal pump (*Masch. Ztg., 4 (1906), No. 16, p. 189*).—In an article by Gramberg in *Brennkohle*, the author mentions a technical but rather important consideration in the operation of the centrifugal pump when same is run by electric motor. "The pressure head against which the pump works is often less than that for which it is designed, and in this case it is found that the motor overheats on long runs, due to excessive current consumption following from the reduction of head. It is a singular fact that a reduction of pressure head should result in an increased power consumption, but such is the case. This is due to the fact that reduction of pressure head causes increase in discharge, the net result being increase in current required. To obviate this loss pumps which are designed for a higher head can be increased in efficiency, by placing a valve in the discharge pipe near the pump. By this means it is possible to produce a throttling effect, increasing the pressure and thereby reducing the discharge, and in turn cutting down the current consumption."

Wind power, E. L. BURNE (*Cassier's Mag., 30 (1906), No. 4, pp. 325-336, figs. 10*).—The writer discusses the various types of wind wheels and

gives data upon their performance under different conditions. Since wind pressure increases as the square of the velocity it follows that the product of speed and pressure increases as the cube of the velocity. The power of the windmill should therefore vary in the same proportion, hence in order to use as much as possible of the force of the wind the mill should operate machinery in which the load increases somewhat in the same proportion as the wind pressure increases with the velocity. For this reason a centrifugal pump works well in combination with a windmill, likewise a constant potential generator for charging storage batteries. Results of experiments by the Danish government are quoted, giving rules for dimensioning and weathering the sails.

Experiments in England conducted by the Royal Agricultural Society are also cited. The dimensions of the mill securing first prize are given in detail. From an analysis of the performance of the various mills it is found that "nothing is gained by providing sail area for more than about 66 per cent of the total surface of the wheel."

"The most suitable angle of weather for the tips of the vanes appears to be about 35 degrees when their velocity is the same as that of the wind. The best number of vanes appears to be a mooted question."

The windmill as a farm power (*Farm Implements*, 20 (1906), No. 9, pp. 42-44).—A popular article transcribed from the *Canadian Thresherman and Farmer*, giving a historical sketch of the development of the windmill and citing some of the experiments which have been conducted from time to time with a view to increasing its efficiency and suitability as a farm and general utility motor.

Dynamo run by windmill (*Engin. and Min. Jour.*, 82 (1906), No. 21, p. 976).—An electric lighting plant operated by wind power is reported to have been installed at Noblesville, Ind., consisting in part of a 14-ft. windmill on a 50-ft. tower. The windmill operates a plunger pump delivering water to a reservoir where pressure is maintained constant by automatic devices. The water under pressure is used when necessary to drive a 5-horsepower turbine wheel, direct-connected to a $\frac{1}{2}$ -horsepower, 25-volt dynamo which charges a storage battery. The battery is of sufficient capacity to light twenty 8-candle-power lamps for 3 hours. In order to generate sufficient current for winter use the windmill must operate 5 hours per day, and for summer use, 2 hours per day.

Test of a small gasoline electric light plant (*Gas Engine*, 8 (1906), No. 11, pp. 348, 349).—This is a report upon a test of a plant of a type used for the lighting of farm residences, barns, and other buildings by the electric incandescent lamp. The engine is belt-connected to the generator and may be used for other power purposes. The test was conducted at the Kansas Agricultural College and showed that for a full load of eighteen 16-candlepower, 110-volt incandescent lamps, the fuel consumption was 1.35 qts. of gasoline per hour. This makes the cost per horsepower hour, \$0.0253, with gasoline selling at 15 cts. per gallon. The fluctuation of voltage was found to be less than 1 per cent when operating at a normal pressure of 110 volts, and the variation in light as compared with lamps supplied with current from the usual steam plant was found to be hardly appreciable.

Explosion motors and the injection of volatile liquids, K. SCHREBER (*Rev. Gén. Sci.*, 17 (1906), No. 16, pp. 734-745, figs. 5).—A mathematical discussion of the desirability of injecting cooling water into the working cylinder of the gas engine. It is concluded that the method of injecting water at the moment of explosion is neither effective nor economical. The author advances particularly

a thermodynamic theory of a 2-cycle alcohol motor with water injection during the compression stroke. This theory is based upon facts drawn from experiments with such a motor of his own invention.

Efficiency tests of a producer gas engine direct-connected to centrifugal pump (*Engin. Rec.*, 54 (1906), No. 20, p. 560, fig. 1).—The results are given of tests upon a producer gas pumping plant, which is one of a number of low-lift pumping stations required to handle large quantities of water under the flood conditions sometimes prevailing in the drainage system of New Orleans. The gas producer has a rated capacity of 100 hp, and supplies gas to a 12.5 by 13 in. 3-cylinder, 2-cycle gas engine connected to a 24-in. centrifugal pump rated at 27 to 30 cu. ft. per second against a total measured lift of 14 ft.

Pittsburg nut anthracite coal, of a heating value of 14,500 British thermal units per 1 lb., was employed, this producing a gas of 115 British thermal units per cubic foot at 60° F. and 760 mm. pressure. The average of the principal results obtained during the 6-day test are as follows:

Revolutions per minute of engine, 296.6; brake horsepower, 70.6; engine efficiency, 78 per cent; pump efficiency, 71 per cent; discharge, 30½ cu. ft. per second; mean velocity of water in pipe, 6.21 ft. per second; total head, 13.36 ft.; coal per hour per brake horsepower, 1.093 lbs.; average duty, 119.6 million foot-pounds per 100 lbs. of coal.

Wood-gas for power purposes (*Masch. Ztg.*, 4 (1906), No. 16, pp. 189, 190).—A producer plant using a species of oak as a fuel is in use at Nacozari, Mexico. The operation consists first in getting a thick bed of glowing coals of light wood and coke, on which the heavier wood is then thrown to a depth of 2 ft., after which the producer is connected to the engine. The preliminary operation requires from 4 to 5 hours. When consuming daily about 15 tons of wood, the generator must be cleaned every 5 days. The average heating value of the gas was found to be 1,028 calories, and the consumption of wood and coke 2.57 lbs. and 0.11 lb., respectively, per electrical horsepower hour. It is stated that considerable advantage is found in this type of plant from the standpoint of economy in fuel consumption, but that in other respects it does not compare favorably with a steam plant.

Denatured alcohol. Investigations in Europe of its cost and use.—What may be expected in the United States (*Daily Consular and Trade Rpts.*, [U. S.], 1906, No. 2666, pp. 1-3).—A denaturing establishment in London is described, consisting merely of tanks arranged on the second, third, and fourth floors of a building and communicating by means of a system of pipes with tanks on the first floor. The tanks on the second, third, and fourth floors contain ethyl alcohol, wood alcohol, and methylated materials, respectively, and the mixing is done in the tanks on the first floor.

It is stated that the idea that alcohol corrodes the cylinders and valves of engines is scoffed at in Germany. With reference to the use of alcohol for illuminating purposes, the following is stated: "Industrial alcohol is now used in Germany in small, portable lamps, which give it all the effects of a mantle burner heated by gas. The expense for alcohol is only about two-thirds as much per candlepower as is the cost of kerosene. Even at 25 or 30 cts. a gallon, denatured alcohol can successfully compete with kerosene as a means of lighting."

Potato evaporating plant and auxiliary operations on Hammer domain, Kr. Wohlan, RHEFELD (*Masch. Ztg.*, 4 (1906), No. 18, pp. 205, 206).—A description of a plant devised to use a portable steam engine of 10 to 12 horsepower, with a boiler of 16-square-meters heating surface. The exhaust steam of the engine is used for the evaporation of the potatoes, and the power deliv-

ered by the engine is used not only for the operation of the evaporator, but also for pumps, oat rollers, shredders and choppers, a circular saw, and milk separators.

The capacity of the plant is 5 tons of raw potatoes of 19 per cent starch content per 24 hours. With less starch content the capacity is correspondingly reduced. The total running expenses per 24 hours are \$6.70. The claim is made that this sort of plant is very profitable, as the dried potatoes can be shipped to distilleries and other potato-using plants at great saving in transportation charges, or in case the market is not favorable, the potatoes can be used as a cattle food, a use for which they are well adapted.

Tarred road. Successful results in France—Application methods (*Daily Consular and Trade Rpts.* [U. S.], 1906, No. 2700, pp. 1-3).—In refutation of a statement to the effect that tarred roads are unsuccessful in France it is affirmed on reliable testimony that tarred roads have been uniformly successful wherever the conditions have been normal and the work properly performed. The method of tar treatment in France is similar to that elsewhere. In the first coating about 1 gal. of liquid tar for 3 sq. yds. is given; in the second coating, 1 gal. for 4 sq. yds.

The tar must be laid on a thoroughly dried and swept surface, otherwise it does not harden readily and is picked up by the wheels of passing vehicles, a circumstance to which is probably due the adverse criticism. Cleaning by machinery does not do the same injury to tar-treated roads as to the ordinary macadam and the protection from wear and tear from this source, as well as the better wearing qualities under the ordinary wear and tear of traffic conditions, is said to produce an economy which balances the extra cost.

New road-tarring machine (*Surveyor*, 30 (1906), No. 767, p. 380, fig. 1).—A machine is described by which the operations of cooking, sprinkling, and spreading by brooms are effected simultaneously. The tar is applied at a temperature of 200° F., and it is claimed that a surface of 2,000 sq. yds. may be uniformly covered per hour. The cost of the first two coats is put at about 1½d. per square yard, with tar at 1½d. per gallon.

A new fertilizer-spreading machine (*Masch. Ztg.*, 3 (1906), No. 17, pp. 200, 201, figs. 3).—In the operation of the usual machine in which the fertilizer is forced by a roller through holes in the bottom of the receptacle a serious difficulty is often experienced by clogging, due to excessive moisture in the fertilizer. To obviate such trouble and to properly disintegrate the material an apparatus has been devised in which "the bottom of the receptacle is formed of two peculiar spring brushes whose ends press upon a roller rotating between them. The roller is provided with projections arranged in a spiral, and when in operation these projections strike the brushes, thus disintegrating the fertilizer and allowing it to escape through the triangle-shaped orifices caused by the opening of the springs forming the brush. The volume of fertilizer to be distributed is varied by changing the number of revolutions of the roller, which is connected to the wheels of the machine by interchangeable gearing."

Cements, limes, and plasters. Their materials, manufacture, and properties, E. C. ECKEL (*New York: John Wiley & Sons; London: Chapman & Hall, Ltd.*, pp. XXXIV+712, pls. 8, figs. 157).—In this volume the author has summarized all the existing information on limes, plasters, and allied materials, the work covering the composition and character of the raw materials, methods of manufacture, and properties of the various cements.

RURAL ECONOMICS.

The new agricultural movement in Cape Colony, P. J. HANNON (*Proc. Roy. Colon. Inst.*, 37 (1905-6), pp. 217-221).—This is a paper read at a meeting of the Royal Colonial Institute of London, in April, 1906.

The author discusses the past and present conditions of agriculture in the colony, and points out the recent progress made in agricultural cooperation in winemaking, creameries, wool industry, animal breeding, growing and marketing fruits, sinking of wells, sheep farming, erection of granaries, construction of irrigation works, introduction of new seeds, and other schemes. The movement is aided by government loans and by registered cooperative associations. Expert advice is also given by government agents in "providing plans and specifications for buildings and plant, as well as making inspections and advising the committees from time to time."

The progress made in agricultural cooperation since 1904 leads the author to hope "that the 'self-help by mutual help' spirit displayed by our farmers, supported by the well-conceived financial assistance of the State, will awaken a wide interest in the future prosperity of this important subcontinent of the British Empire."

Cooperation in agriculture (*Agr. Jour. Cape Good Hope*, 29 (1906), Nos. 3, pp. 331-342; 4, pp. 512-517).—This consists of extracts from the report of P. J. Hannon, superintendent of agricultural cooperation in the colony. The results are noted from another source (see above).

The new agriculture, B. LANDRETH (*Proc. Amer. Phil. Soc.*, 45 (1906), No. 183, pp. 166-177).—This paper briefly describes the progress made in the application of steam, electricity, and scientific knowledge to agriculture, along the lines of the preparation of the soil, harvesting crops, control of insect pests and fungus diseases, forcing of plants, soil inoculation, and the use of electric air currents in plant development.

The organization of agriculture in the Netherlands, J. FROST (*Agrarverfassung und Landwirthschaft in den Niederlanden*. Berlin: German Agr. Soc., 1906, pp. 495, maps 6).—This is a general treatise on the development and organization of agriculture and related industries in the Lowlands.

Statistical data are reported and discussed in part 1 regarding the climate, classes of land under cultivation, waterways and highways, and transportation facilities.

Parts 1 to 3 deal more directly with the economic aspects of agriculture, and include information regarding the past and present status of farm holdings, labor relations, agricultural organizations and education, systems of culture, crops raised and disposition of crops, animal production, cooperative societies for the purchase and sale of products, the methods of raising capital for investment, and other topics relating to the economics of agriculture.

Annual report on the working of the cooperative credit societies act of 1904 in the Bombay Presidency during the year ending 31st March, 1906, J. MCNEIL (*Bombay: Govt.*, 1906, pp. 23).—Included in the report are tabulated statistics giving details of each society as to origin, location, receipts and disbursements, rates of interest, assets and liabilities, profits and loss of operation, and classification of loans. In summarizing the year's work, the author says: "The general progress made is, I think, satisfactory. While the number registered at the close of the year was 31, the total number now registered [July 10, 1906] is 45 in 11 districts and the city of Bombay. The only failure is the rural society at Unkal."

Report on trade in agricultural products, L. VASSILLIERE (*Notice sur le Commerce des Produits Agricoles. Paris: Gort., 1906, pp. VII + 461, maps 3*).—This report contains detailed information regarding the extent and disposition of agricultural plant products in France, a forthcoming volume being devoted to similar data relating to animal production.

The situation, configuration, and climate of each department are described, and the adaptability of each province for raising certain crops is indicated. Statistics are then given relating to the production of forestry products, forage crops, cereals, vegetables, fruits, and flowers in the various divisions of each province, the quantities there utilized as food supplies or in manufactures, and the amounts shipped to other departments and foreign countries, the statistics being frequently compared with similar data for preceding years.

A detailed list is appended of the principal places in each province devoted to the raising of definite crops, particularly fruits and garden truck.

The world's grain production in 1906 (*Die Getreideproduktion der Welt im Jahre 1906. Budapest: Min. Agr., 1906, pp. 116*).—The data tabulated and discussed in this volume include the number of hectares planted to different grain crops, the yields per acre, total yields in various countries, and the classes and quantities of grain imported and exported by the great grain-consuming and grain-producing countries of the world. The statistics given are for the year 1906 in comparison with the two preceding years.

[**Agricultural statistics, 1905**], E. T. MULLENS (*Rpt. Min. Agr. Natal, 1906, pp. 32, dgm. 1*).—This report by the minister of agriculture for the Colony of Natal gives detailed notes on the opening up of Zululand for farm settlement and the extent of colonial progress in agriculture, and reports statistics relating to special and general farm products imported and exported during the year 1905, the development of the various industries being indicated by reference to similar data for the year 1896.

An appendix contains a report by J. C. Parker as to the results of trout introduction into Natal.

Third report on Hawaii (*Bur. of Labor [U. S.] Bul. 66, pp. 365-688*).—This report by the United States Commissioner of Labor relates in general to all forms of labor in Hawaii. But since the islands, on account of their volcanic origin, are "dependent for economic prosperity upon agriculture alone," the statistics presented and discussed relate mainly to this industry.

The bulletin furnishes detailed data on the capital invested in agricultural pursuits, dominance of the sugar industry in Hawaii, number and character of the rural population, extent of immigration and emigration of oriental labor, land and its settlement, small farming, stock raising, different classes of farm labor and their standards of living, together with other statistics bearing on the agricultural and industrial development of Hawaii.

AGRICULTURAL EDUCATION.

Agricultural education, L. H. BAILEY (*Ann. Rpt. N. J. Bd. Agr., 33 (1905), pp. 131-154*).—In this address is given a brief account of the early discussions and movements for agricultural education in this country, dating from 1794 to about 1860. Michigan is given credit for the oldest existing agricultural college in North America, which was opened to students in 1857, and F. G. Cary is said to be "practically the first professor of agriculture in this country, since he seems to have been the first to successfully organize a college for this kind of work." This was a literary academy started in 1833 at College Hill, near Cincinnati. "It gradually took hold of the affairs of the community and became 'The Farmer's College,' but "finally passed into a military institute."

The gradual evolution is traced of the idea that the State in some way should foster agricultural education. The question of class education is disposed of by the statement that the primary object of the agricultural colleges is "not to make farmers but to make citizens, and the State is always justified in educating citizens. These citizens who live on farms should be educated in terms of their own lives if they are to be efficient citizens." Other classes of citizens are said to be benefited more than farmers by tariffs and other forms of legislation, hence the maintenance of agricultural education may be considered in part an offset for the special privileges the State gives to other classes of citizens.

The enactment of the Land-Grant Act of 1862, the second Morrill Act, and the Hatch Act are taken as indications that the policy of extending Government aid to agricultural institutions is now well accepted. It is argued that the States themselves should contribute liberally to the support of these institutions.

The progress of the agricultural colleges in developing this new education is traced, and attention is called to the work now being done to develop courses in home economics and to the desirability of improving the architecture of farm buildings and developing courses in rural economics and rural sociology. "The result of all this work has come to be that the general tone of farm life has been greatly elevated."

The need of improved country schools is pointed out, and the work of the agricultural colleges in bringing about improvement in these schools is commented on. As a result of this it is said that "about 40 of the States, Territories and provinces have taken some kind of official action looking toward the introduction of agriculture and nature study into the schools." The writer thinks it a mistake to push technical agriculture into these schools very rapidly. "The general pedagogical efficiency of the school must be elevated, the agricultural work coming gradually and naturally as the school develops." But "some kind of local work is essential for the best efficiency in every school, and in the rural districts this local work is necessarily largely agricultural. If the existing schools can not handle these local subjects satisfactorily, it is an indictment against their efficiency as educational means."

Agriculture as taught in summer schools for teachers, the movement for the consolidation of rural schools, and the organization of special agricultural schools are other topics considered in this connection. Attention is also given to changes needed in methods of teaching so as to make reading, number work, geography, and manual training more suitable for rural communities. The winter course of instruction in agricultural colleges is mentioned as one of the temporary but necessary and highly important features of agricultural college instruction.

The American school system with special reference to institutions for agricultural instruction, H. MATZAT (*Landw. Jahrb.*, 35 (1906), No. 5, pp. 667-737).—This is a description of the American system of education, based on information gathered by the writer in a visit to the Louisiana Purchase Exposition and to leading educational institutions in different parts of the United States, as well as on the study of numerous text-books, reports, and published articles. As a basis for a better understanding of the system of agricultural education, a description is given of educational institutions in general, including elementary and secondary schools and colleges, and the system of managing schools, teachers, coeducation, etc., is discussed.

Under the topic, Agricultural Education in America, the writer discusses its history and development, the scientific study of agriculture, higher agricultural instruction, and secondary and primary agricultural instruction, and endeavors to draw conclusions with reference to the application of American methods to German institutions. He gives at considerable length the courses of study and

methods followed by a number of the leading American agricultural colleges, and gives figures to show the number of students taking the four-year agricultural courses in all of the agricultural institutions in this country.

The writer concludes that, judging by the rapid progress America is making in education, it is in a fair way to outstrip Germany not only in agricultural, industrial, and commercial lines, but also intellectually. The principal advantage he finds in the American system of education is free tuition, by means of which talent wherever found is stimulated to free and full development. He quotes figures to show that in America it is eight times as easy for the children of poor parents to go through the secondary schools and colleges as it is in Prussia, and concludes that it is not strange therefore that self-made men are so much more numerous in America than they are in Prussia. He favors the extension of the free-school system in Prussia as rapidly as circumstances will permit, and recommends as a first step in this extension the development of winter courses in the regular schools by means of which country children from 11 to 13 years of age, who are needed at home during the summer, may be able to attend school during the winter months and continue to do this until they are 16 or 17 years old.

He also finds that the greater adaptability of American schools to local conditions is worthy of imitation. He favors the extension of the system of elective courses, and also believes that the Prussian schools devote too much time to language study for the purpose of acquiring facility in the use of words rather than the acquirement of facts. And, finally, he says that Prussian schools have no occasion to rest on their laurels, but should rather watch American progress and not delay too long the adoption of such improvements as are practicable.

MISCELLANEOUS.

Experiment Station Work, XXXVII (*U. S. Dept. Agr., Farmers' Bul.* 267, pp. 32, fig. 1).—This number contains articles on the following subjects: Breeding corn; buckwheat; sugar beets on alkali soils; alfalfa as a forage plant; apple bitter rot; grass mulch for orchards; hardiness of young fruit trees; protecting cows from flies; effect of silage on milk; and cold storage of cheese.

Farmers' bulletin subject index, G. W. HILL (*U. S. Dept. Agr., Div. Pubs. Circ.* 4, pp. 13).—A list of subjects in alphabetical order of the Farmers' Bulletins now available for distribution.

The healthful farmhouse, HELEN DODD (*Boston: Whitcomb & Barrows, 1906*, pp. X+69, pls. 5, figs. 8, dym. 3).—On the basis of experience the arrangement and care of different rooms in the farmhouse are discussed with a view to securing greater comfort and lessening work, and suggestions are made regarding plumbing, furnishing, and related questions.

The volume contains an introduction and a supplementary chapter on the opportunity of the consolidated school by Ellen H. Richards, particularly along manual training lines.

NOTES.

Colorado College and Station.—The legislature has been asked for considerable funds for new buildings, additional equipment, and extension of investigations.

Georgia College.—A department of forestry has been inaugurated at the University of Georgia, with Alfred Akerman, formerly State Forester of Massachusetts, in charge.

Iowa College.—The various short courses offered by the college this year enrolled nearly 1,000 students. The board of trustees donated a free scholarship to each farmers' institute in the State, and these scholarships were awarded to about 100 students.

Kansas College.—The *Industrialist* states that the total enrollment is now nearly 2,000. Many parallel classes have been organized and more will be required. The new horticultural hall, though not yet completed, is fully occupied. A very successful series of meetings was held at the college from December 27 to January 5. These included a State farmers' institute with classes in grain and stock judging, meetings of the Boys' Corn Contest Association, the State Corn Breeders' Association, Good Roads Association, Draft Horse Breeders' Association, Dairy Association, Aberdeen Angus Association, and swine breeders.

Louisiana Stations.—W. G. Taggart and A. P. Kerr, of the Mississippi College, have been appointed analytical chemists at the Baton Rouge Station. A. B. Joffrion has resigned to accept a position in a large sugar factory in Porto Rico.

Massachusetts College and Station.—A bill has been introduced into the legislature to change the name of the station from the Hatch Experiment Station of the Massachusetts Agricultural College to the Massachusetts Agricultural Experiment Station. A professorship of pomology is to be established in the college. H. F. Tompson, a graduate of the college in 1905, has been appointed instructor in market gardening and supervisor of field work. Prof. G. F. Mills has been made dean of the college and professor of the humanities, a chair newly established, having for its object the closer correlation of the agricultural, technical, scientific, and cultural studies of the curriculum.

Michigan College.—F. H. Sanford, a graduate of the college in 1904, has been appointed instructor in forestry to assist Professor Bogue.

Nebraska University and Station.—We learn from *Agriculture* that the legislature is to be asked for \$220,000, of which \$180,000 is for the completion of a woman's building, horticultural building, judging pavilion, and poultry plant in the college of agriculture; \$25,000 for the maintenance of the substation at North Platte, and \$15,000 for farmers' institutes.

Ohio Station.—J. H. Show has resigned as assistant chemist and has been succeeded by S. S. Fay, of the University of Nebraska. The station has begun the erection of a glass house to be used in soil study.

Rhode Island Station.—A. W. Richardson, assistant in agronomy, has resigned and is succeeded by S. C. Damon.

South Dakota Station.—At a recent meeting of the board of regents a resolution was adopted, pointing out the desirability of establishing at least two

new substations for dry land farming, one for the northern and one for the central portion of the tract lying west of the Missouri River. It is proposed that these branch stations shall be under the management and control of the station at Brookings, and an initial appropriation of at least \$3,500 for each is mentioned, with \$3,000 annually thereafter. The resolution is to be presented to the legislature with request for action, including the setting aside of at least two sections of land for the use of the proposed substation.

Virginia College and Station.—The agricultural club of the college of agriculture has begun the publication of a bi-monthly periodical, called the *V. P. I. Agricultural Journal*. Harry H. Hill has been appointed assistant in the chemical department of the station.

Wyoming University and Station.—G. E. Morton, of the department of animal husbandry, has resigned to accept a similar position in the Colorado College. John A. Hill, a senior student in agriculture in the university, is taking up special work at the Philadelphia Textile School in preparation for researches upon wool at the station. This work will consist chiefly of studies of Wyoming wools and wool scouring, and the effect of different feeds, alkali soils, and cross-breeding on the character and quality of western wools. The station recently obtained 72 breeding ewes from different parts of the West, to be used in breeding experiments under range conditions in cooperation with the Bureau of Animal Industry, in an attempt to establish a typical western range sheep with improved mutton qualities and which will shear a heavy fleece of fine wool.

A new series of dry farming investigations have also been undertaken in cooperation with the Irrigation and Drainage Investigations of this Office. In this connection the station will take up the study of soil moisture and its conservation to determine some of the underlying principles of successful farming without irrigation, where the rainfall is less than 15 in.

Association of American Agricultural Colleges and Experiment Stations.—It is announced by the executive committee that the next meeting will be held at Lansing, Mich., during the week of May 26.

Georgia Agricultural Schools.—Meetings of trustees to decide upon the location of Congressional district industrial and agricultural schools in Georgia have been held in 10 of the 11 districts. In nearly every instance the competition between different localities in the districts has been very sharp, and the contributions, consisting of pledges of funds, land, electric lights, water, sewer systems, telephone service, etc., have been liberal. The smallest cash contribution for buildings was \$15,000 and the largest \$60,000.

The location of the schools and the estimated value of the contributions in the different districts are as follows: First district, Statesboro, \$100,000; second district, Tifton, \$110,000; third district, Americus, \$75,000; fourth district, Carrollton, \$60,000; fifth district, Monroe, \$50,000; sixth district, Barnesville, \$86,000; seventh district, Powder Springs, \$40,000; eighth district, Madison, \$75,500; ninth district, school not yet located; tenth district, Granite Hill, \$58,000; eleventh district, Douglas, \$90,000.

Plans for the different buildings, subject to slight modifications by the respective boards of trustees, have been drawn by an architect employed by Governor Terrell. These plans contemplate a main building, a girls' dormitory, a boys' dormitory, a domestic science and dining hall, power house and shops, 4 cottages for instructors, and barns and other farm buildings. The main building and at least one dormitory will be erected at once in every district, and in some districts the girls' dormitory, the power house and shops, and the domestic science and dining hall will be erected at the same time.

At a recent meeting the board of trustees of the Georgia State College of Agriculture and Mechanic Arts decided that the minimum age for entrance into

the schools be 14 years for boys and 13 years for girls; that the course of study be limited to 4 years, one of which shall include common school or elementary studies, and that the scholastic year be 40 weeks. A minimum of 3 hours of class-room work in agriculture and related sciences, English, mathematics, and history, and 3 hours on the farm, in the shop, or the laboratory was decided upon. One-fourth of the students will be required to remain on the farm during the summer vacation and will receive compensation for their work. A course of study prepared by Prof. J. S. Stewart, of the State university, and D. J. Crosby, of this Office, was recommended.

Rothamsted Station.—The following note regarding the station is copied from *The Gardeners' Chronicle*: "The Rothamsted Experimental Station (Laws Agricultural Trust) has received a donation of £2,000 from the Permanent Nitrate Committee, to be invested and added to the general endowment fund of the station. A donation of 100 guineas [about \$500] has also been received from the Fertilizer Manufacturers' Association.

"During the past summer the station entered into occupation of the 'James Mason' Bacteriological Laboratory, the gift of Mr. J. F. Mason, M.P. The society for extending the Rothamsted experiments, which was formed to obtain funds wherewith the experimental station might enlarge the scope of its work and initiate further agricultural investigations, has further received during the past year subscriptions and donations amounting to £240. Further subscriptions are still urgently needed to secure a more adequate staff, and may be addressed to the secretary of the Rothamsted Experimental Station, Harpenden, Hertfordshire."

Agricultural Measures before Congress.—A bill has been recently introduced by Senator Clay and Representative Adamson, providing an annual appropriation of \$2,500 for branch agricultural experiment stations. These stations are to be established under the direction of the stations now in existence, and the appropriation can be applied only to the expenses of conducting or verifying experiments bearing directly on agricultural industry.

A similar bill has been introduced by Representative Davis, which includes in addition an annual appropriation for industrial education in agricultural high schools and in city high schools.

Other measures recently introduced include bills authorizing experimentation by the Secretary of Agriculture in reference to cotton bollworm and cotton wilt disease; to prohibit the transmission of interstate or foreign messages regarding the buying or selling of "futures" in agricultural products or commodities; to provide for a soil survey in Hawaii; to establish a National wood-testing laboratory; to provide for the investigation of the water resources of the United States; to appropriate \$100,000 for the establishment of demonstration farms, for the investigation of farm practice, and the inauguration of systems of farm management; to provide for fixing uniform standards of classification and grading of grain; to provide for the establishment of an agricultural bank in the Philippines; to refund 30 per cent of all money received from forest reserves to the respective States or Territories, for the benefit of the public schools and roads; to prevent the sale of adulterated and misbranded seed; to provide for the printing of 250,000 copies of the special report on the diseases of the horse; to aid in the settlement and irrigation of lands included in National reclamation projects, by setting aside 40 acres of land in each case for experiments in irrigation and drainage; and providing for the control of grazing upon the public lands.

Rosenbaum Live Stock Prizes.—Special prizes offered at the International Live Stock Exposition by Rosenbaum Brothers & Co., of Chicago, have been awarded, according to the winnings at the exposition of exhibitors from the

various States, to their respective stations, as follows: Illinois first, \$500; Indiana second, \$300; and Iowa third, \$200. These awards are to be used as prizes on live stock or to successful students in judging live stock and grain at the short winter courses.

Horse Breeding in Japan.—*Farmers' Advocate and Farm Journal* notes the formation of an organization, with headquarters at Tokyo, for the purpose of promoting improvement in the quality of Japanese horses. Half the shares in the company are in the hands of the government, which makes an appropriation for that purpose. Private capital promptly oversubscribed its portion of 150,000 yen (about \$150,000). Importations have been begun and competitions and public demonstrations are to be arranged.

Agricultural Fraternity.—*Farm Students' Review* states that the students in the college of agriculture of Ohio State University, with the approval of members of the agricultural faculty, have established a fraternity, *Delta Theta Sigma*, to stand strictly for advancement in agriculture and extend its development.

Necrology.—On October 26, 1906, Johann Dzierzon, one of the oldest and most famous investigators in the line of apiculture, died in Silesia at the age of 93 years. In many respects he was the Nestor of bee raisers and suggested many practical devices which are not always associated with his name, among them a separable hive similar to that invented by Langstroth about the same time. He is chiefly known throughout the world, however, on account of his announcement, in 1853, of parthenogenesis in bees. Much controversy has developed around this point in late years, but Dzierzon's theory has received substantial support from the majority of investigators.

William Warfield, a famous American breeder of Shorthorn cattle, and the author of one of the standard treatises on breeding animals, died recently in his eighty-third year.

Dr. Walter J. Sykes, for the last 15 years editor of the *Analyst*, died at Westfields, Grimstead, December 16, 1906, at the age of 64. He was educated in the medical profession but became interested in the chemistry of brewing, to the literature of which he made a number of contributions, notably *The Principles and Practice of Brewing*, the second edition of which is now in press. Among his investigations were studies of differentiation of various nitrogenous constituents of malt wort, and, together with C. A. Mitchell, of the diastatic power of malt. As editor of the *Analyst*, he was the author of a number of educational papers of value, and took a prominent part in popularizing the work of Hansen on yeasts and Emil Fischer on sugars.

Miscellaneous.—The opening of the agricultural exposition in Paraguay has again been postponed, and will take place March 31.

Pioneer Mail states that a new government farm wholly for tobacco research is to be opened in Rangpur district of Bengal, one of the most important tobacco-raising areas in India.

Kew Bulletin announces that Capt. A. T. Gage has been appointed superintendent of the Royal Botanical Gardens of Calcutta and director of the botanical survey of India.

Sidney Wells, principal of the Battersea Polytechnic, has been appointed director-general of the department of agriculture and technical education for Egypt. This department has been created to develop, organize, and control technical education in Egypt, and will be concerned with the government educational institutions of every kind, and also with the nongovernment technical institutions.

Fuller's earth test for caramel in vinegar, Dubois.....	610

METEOROLOGY—WATER.

	Page.
Climatology of the United States, Henry	611
Forty years of southern New Mexico climate, Tinsley	611
World weather, Eliot	611
Monthly Weather Review, Vol. XXXIV, Nos. 9, 10	611
Meteorological observations, Ostrander and Barry	612
Meteorological summary for 1905, Patton	612
Peruvian meteorology, 1892-1895, Bailey	613
Meteorology, von Dodelszen	613
Weather observation, Martin	613
The meteorological service of the Republic of Mexico, Pastrana	613
Résumé of researches in the higher meteorology, Bigelow	613
Storms and hail, Daguilhon-Pujol	613
Thunderstorms and the moon, Hissink	613
The sanitation of air, Meier	613
Surface trajectories of moving air, Shaw and Lempfort	614
Progress in the field of water investigations, Krauss	614
Springs in limestone regions for drinking purposes, Schardt	614
Contribution concerning purification of water by ozone, Rivas	614
Control of water purification plants, von Cochenhausen	614
A sand filter for the home, Fletcher	614

SOILS—FERTILIZERS.

A treatise on rocks, rock-weathering, and soils, Merrill	615
Studies on the soils of the third steppe, Alway and Gortner	615
Maintaining the fertility of rice soils, Fraps	615
Results of analyses of cultivated soils, Villaseñor	616
Protective action of colloids on clay soils, Fickendey and Tollens	616
Nitrogen compounds in cultivated soils, Pfeiffer and Ehrenberg	617
Nitrogen compounds in cultivated soils, Pfeiffer	617
Evaporation and drainage from soils, von Seelhorst	617
Nitro-culture and inoculation, Ball	617
Nutrition of cultivated plants, Smets	618
Management of stable manure in the heap, Stufzer	618
Storage of liquid manure	618
Value of moss litter	618
Water as a plant food, Backhaus	618
Artificial manures in Japan	618
Report on commercial fertilizers, 1906, Jenkins, Winton, et al.	618
Fertilizer inspection, Woods and Bartlett	619
Commercial fertilizers, Wheeler et al.	619
Analyses of commercial fertilizers, Hartwell et al.	619
Commercial fertilizers and chemicals, Hudson, McCandless, et al.	619
Test of nine phosphates with different plants, Wheeler and Adams	619
Tests of Thomas slag and agricultural phosphate, Clausen	620
Tests of Thomas slag and agricultural phosphate, Bachmann	621
Tests of Thomas slag and agricultural phosphate, Böttcher and Bachmann	621
Phosphate of lime in Algeria	621
Crude ammonia, de Molinari and Ligot	621
Cause of lower efficiency of ammoniacal nitrogen	621
Fertilizing action of sulphate of ammonia, Kretschmer et al.	622
Is nitrogen lost in fertilizing with nitrate of soda? Stoklasa	622
Can calcareous fertilizers be held responsible for a deficiency of nitrogen in soils? Clausen	622
Nitrate of soda, Plagemann	623
Lime niter for potatoes, Grandeau	623
Dry fertilizer from by-products or residues from sugar works, Lallemand	623
On the use of sulphocyanids as fertilizers, Perotti	623

AGRICULTURAL BOTANY.

Botanical studies applied to agricultural plants, Fron	623
Hybridization of wild plants, MacDougal	624
Action of ozone on germination, Micheels and De Heen	624
Stimulating action of manganese on germination, Micheels and De Heen	624

	Page.
Effect of solar radiations on nitrogen content of wheat, Dumont.....	624
Toxic limits of some salts and poisons on wheat, Jensen.....	625
Some investigations on the injury to plants by sewage, Ehrenberg.....	625
Concentration of nutrient solutions on development of algae, Artari.....	625
Tannin cells of persimmons, Howard.....	626
Study of beans yielding hydrocyanic acid, Guignard.....	626
A second Ohio weed manual, Selby.....	627

FIELD CROPS.

A successful hog and seed-corn farm, Spillman.....	627
Forage-crop practices in western Oregon and western Washington, Hunter.....	627
Annual report of Burdwan Experiment Station, 1905-6, Smith.....	627
Annual report of Cuttack Experiment Station, 1905-6, Smith.....	628
Annual report of Dumraon Experiment Station, 1905-6, Smith.....	628
The state farms, Despeisses.....	628
Experimental stations [Report on field crops], Clifton.....	628
[Report on pasture and old land hay plats], Gilchrist.....	629
Utilization of water by rye, barley, wheat, and potatoes, Seelhorst.....	629
Effect of injury to spike and stem of grains, Eberhart and Metzner.....	630
Alfalfa seed testing, Ball.....	630
Fertilizer experiments with brewing barley in 1906, Reitnair et al.....	630
Corn selection, Card.....	631
Selection, and preparation of seed corn, Wiancko and Christie.....	631
Hints on preparing for and holding local corn shows, Wiancko and Fisher.....	631
Breeding an early, rapid-fruiting, and productive cotton, Bennett.....	631
Improvement of the cottons of the Bombay Presidency, Fletcher.....	631
Supply and distribution of cotton, Roper.....	632
Culture and utilization of cyperus, Bui-Quang-Chiêu.....	632
Flax culture, Bolley.....	632
The extension of jute cultivation in India, Finlow.....	633
Mineral matter in oat stems in relation to lodging, Lienan and Stutzer.....	633
Potato investigations, Green and Waid.....	633
Rice culture in Tonkin, Bui-Quang-Chiêu.....	633
Influence of fertilizer on composition of rye, de Grazia and Caldieri.....	633
<i>Solanum commersoni</i> , Bussard.....	634
Breeding seedling varieties of sugar-cane, Kobus.....	634
Sugar-cane experiment station, Sedgwick.....	634
Saving the sweet potato crop, Carver.....	634
Technical bulletin on cultivation of tobacco, Splendore.....	634
Typical variety of <i>Nicotiana tabacum</i> , Anastasia.....	635
Typical varieties of wheat grown in New South Wales, Guthrie.....	635

HORTICULTURE.

Laboratory work in plant breeding, Emerson.....	635
Fertilizing garden crops with lime-nitrogen.....	635
A new muskmelon.....	635
Chillies or capsicums, Buttenshaw.....	635
Study on <i>Rheum raphaniticum</i> , Cristofoletti.....	636
Horticultural section, Palmer.....	636
Hypodermic injections in plants.....	636
Importance of lime as a plant food for seedlings, von Brehmer.....	636
Plant breeding in relation to American pomology, Munson.....	636
Results from work in breeding hardy fruits, Patten.....	637
Crop improvement by utilizing wild species, Bessey.....	637
A curious effect of grafting by approach, Nombrot.....	637
Fruit varieties most popular on the Pacific Slope, Wickson.....	637
Peach growing in Texas, Kyle.....	637
Olive pickling, Bioletti.....	637
Growing oranges forty years, Stringfellow.....	638
Date palm, Fletcher.....	638
Mangoes, Beach.....	638
California crop statistics 1905-6.....	638
Cocoanuts, Hubert.....	638
The cacao plantation in French Congo, Chalot, and Luc.....	638

	Page.
Importance of shade trees in cacao culture, van Hall	638
Varieties of cultivated pepper, Barber	639
Every farmer can raise evergreens, Harrison	639
The action of ether in forcing plants	639

FORESTRY.

Forest planting in eastern Nebraska, Miller	640
Holding force of railroad spikes in wooden ties, Hatt	640
Strength of packing boxes of various woods, Hatt	641
Kiln-drying hard-wood lumber, Dunlap	641
Timber used in mines of the United States in 1905, Kellogg	642
Wood used for distillation in 1905, Hale	642
Wood used for veneer in 1905, Hale	642
Lumber cut of the United States in 1905, Kellogg	642
Influence of forests on regulation of water supply, Eardley-Wilmot	643
Forest litter and nitrogen, Hornberger	643
Effect of moon's phases on period of felling bamboos, Stebbing	643
Note on chilgoza forests of Zhob and the Takht-I-Suliman, Stebbing	643
Caoutchouc in Indo-China, C. and A. Spire	644
Contribution to the chemistry of gutta-percha and caoutchouc, Müller	644

DISEASES OF PLANTS.

Plant diseases in Bulgaria, Malkoff	644
Report of Royal Servian experiment station, 1903-1905, Ranojewić	644
Agricultural botanical report for 1906, Eriksson	644
Report of the government botanist, Barber	645
Species of <i>Fusarium</i> and plant diseases they cause, Appel and Schikorra	645
Monograph of the genus <i>Ravenelia</i> , Dietel	645
A new fungus of cereals, Jungner	645
Wheat mildew, Musson	645
Germinative ability of old ergot sclerotia, Zimmermann	645
Potato diseases, Lange	646
Contribution to knowledge of potato scab, Güssow	646
Bacterial rot of potato caused by <i>Bacillus solaniscaprus</i> , Harrison	646
The heart rot of beets, Merle	647
<i>Sclerotinia libertiana</i> as cause of rotting of root crops, Appel and Bruck	647
A grass destroying myxomycete, Wulff	647
The clover broom rape, Marre	647
Eelworms, Collinge	647
Experiments with tomato blight, Orr	648
Cranberry diseases, Shear	648
The bacterial disease of ginger, Uyeda	648
Further contribution to infectious chlorosis of mallows, Baur	648
Soil treatment for the forcing house, Selby	648
Causes contributing to black rot due to <i>Sclerotinia fructigena</i> , Molz	648
Melanose, <i>Cladosporium</i> , and <i>Septosporium</i> , Marsais	649
Notes on the disease of grapes known as roncet, Ereole	649
Notes on folletage of the grape, Ravaz	649
The American gooseberry mildew, Salmon	649
Means employed to combat gooseberry mildew in Sweden, Eriksson	649
Investigations on the bacteriosis of figs, Petri	649
A disease of coffee in Peru, Hecq	650
A disease of hazelnuts, Schellenberg	650
A fungus disease of the cherry laurel, Salmon	650
A disease of fir, Mangin and Hariot	650
On the parasitism of <i>Merulius lacrymans</i> , Appel	650
A strangling disease of young birches, Laubert	650

ECONOMIC ZOOLOGY—ENTOMOLOGY.

General biology, Hertwig	651
Rabbit destruction	651
The serpents of Pennsylvania, Surface	651
The destruction of injurious mollusks, Gándara	651
Variation in parthenogenetic insects, Kellogg	651

	Page
Zoological studies in Illinois and Mississippi River valleys, Hart	651
Report of the economic zoologist, Surface	651
Insect notes for 1906, Patch	652
Notes on some Fijian insects, Muir	652
Some injurious insects, Soch and Bartlett	652
Horticultural insect enemies, Van Dine	652
Some of the Coccinellidae, Dimmock	652
Notes on certain cranberry-bog insects, Franklin	652
The important forest insects, Grönberg	652
The Hessian fly, Gossard and Houser	652
The locust plague, Pizarro	653
The locust invasion, Lounsbury	653
The control of locusts, Lahille	653
The rice grasshopper, Knight and Dixon	653
The San José or Chinese scale, Marlatt	653
The San José scale in Alabama, Cardoza	653
Commercial miscible oils for San José scale, Parrott et al.	653
Miscible oil sprays, Hall	654
Patent washes for San José scale, Craig	654
Line-sulphur wash studies, 1904-1906, Phillips	654
The codling moth, Börner	654
A new cabbage-eating larva, Carpenter	654
A new enemy of the raspberry, Marchal and Verrier	654
Life history of a coelidid moth (<i>Adoneta bicaudata</i>), Dyar	654
The winter spraying of fruit trees, Collinge	654
Tobacco as an insecticide, Inda	655
An apparatus for testing the value of fumigating agents, Kendall	655
White ants, Desneux	655
Life history of <i>Stomoxys calcitrans</i> , Newstead	655
Some Scottish Ixodidae (ticks), Evans	655
Improvement of honeybees, Benton	655
Swarming of bees, von Buttel-Reepen	655
Foul brood and other disease of bees, France	655
Laws against injurious insects in the United States, Howard and Burgess	655

FOODS—HUMAN NUTRITION.

Elements of the science of nutrition, Lusk	656
Human foods, J. Alquier	656
Human food, Alquier	656
Food analyses, V. Willard	656
Bleaching of flour, Ladd and Stallings	657
Indian corn as food for man, Merrill	657
Dietary study of laborers and clerks in Paris, Landouzy et al.	658
New method of testing the functions of the digestive apparatus, Einhorn	658
Acceleration of action of pancreatic juice by salts of calcium, Delezenne	659
Chemical processes in the animal body, Herzog	659
Chemical studies on growth, Mendel	660
Metabolism experiments with phosphorus, LeClere and Cook	660
Nitrogenous metabolism as affected by diet and by diuretics, Haskins	661
Metabolism of creatin and creatinin, Folin	661
Carbohydrate metabolism, Pavy	661
Some properties of the albumens present in duck egg white, Panormow	661
Concerning dried fruit, Stecher	662
The acidity of fruits, Sutherst	662
Canned artichokes, Carles	662
Chuño, a frozen potato product from Bolivia, Parow	662
Concerning spices, Sprinkmeyer and Fürstenberg	662
Digestion experiments with chestnuts, Merrill	662
Marula nuts	663

ANIMAL PRODUCTION.

Foods and fodder plants, Dunstan	663
Commercial feeding stuffs, Mairs	663
Properties of cell walls, Fürstenberg, Mordfield, and König	664

	Page.
The use of locusts as food, Ingle	665
Farm animals, Wilcox	665
Steer feeding, Skinner and Cochel	665
The feeding of beef cattle, Butler	666
Cattle-feeding experiment, Bruce	666
Sheep-feeding experiment, Bruce	666
Feeding fermented cotton-seed meal to hogs, Marshall	667
Egg farming—infertile eggs, Fern	668
Ostrich farming as carried on at the present day, Douglass	668
The turtle trade of the West Indies, Fitz Gerald	668

DAIRY FARMING—DAIRYING—AGROTECHNY.

Determination of protein minimum in rations for dairy cows	668
The fat content of cows' milk, Högström	669
Cow testing associations, with notes on testing milk, Ruddick and Whitley	670
Milking machines, Erf	671
Formation of lactose, Marshall and Kirkness	671
Homogenized milk, Eury	672
Source and distribution of organisms ofropy milk, Schneebeli	672
Pathogenicity of <i>Streptococcus lacticus</i> , Heinemann	672
Report of the butter laboratory in Hängo, Finland, 1904, Bredenberg	672
Butter trade in Denmark, France, and Holland, Hollmann et al.	673
Influence of pepsin upon ripening of Limburg cheese, Marcus and Huyge	673
Action of rennet on milk, Slowtzoff	673
Fundamental dairying and dairy arithmetic, Erf	673
First national congress of dairying	673
Pure yeast in wineries, Bioletti	673
Defecation of must for white wine, Bioletti	674
Beet-sugar manufacture, Claassen, trans. by Hall and Rolfe	674
Distillation of alcohol from farm products and denaturing alcohol, Wright	674

VETERINARY MEDICINE.

Treatise on domestic animals in health and disease, Koch	674
A text-book upon the pathogenic bacteria, McFarland	674
The toxins and venoms and their antibodies, Pozzi-Escot, trans. by Cohn	674
Rôle of leucocytes in defense of organism against infection, Pettersson	674
Causes of diminution of natural resistance to infection, Tromsdorf	675
Relation of autolysis to histological changes in necrotic areas, Wells	675
Proceedings of free society for micro-biology in Berlin, Wassermann	675
Transmission of resistance to diphtheria by female guinea pig, Anderson	675
Pathogenic action of blastomycetes injected into the trachea, Sanfelice	675
Locked jaw induced by tetanus toxin, Roaf and Sherrington	676
Treatment of tetanus by the method of Baccelli, Bianchedi	676
Danzysz' reaction, Madsen and Arrhenius	676
Infection in tuberculosis, Mettam	676
Immunization to tuberculosis, Haan	676
Cornstalk disease, Craig	676
Treatment of milk fever, Rabus	677
Ranula inflammatoria in cows, Wyssmann	677
Alterations in mucus membrane in strongylosis in cattle, Blunsky	677
Fatal hemorrhage of a tuberculous ulcer of the fourth stomach, Plate	677
Poisoning from the use of spoiled brewers' grains, Schilffarth	677
Nodule disease of the intestines of sheep, Dalrymple	677
Epizootic gangrenous mammitis in ewes, Detroye	677
A disease of the pig due to Spirochæta, Dodd	678
Pseudoleukemia in pigs, Rottke	678
Rachitis accompanied with spasms in pigs, Fromberg	678
Susceptibility of ruminants and apes to dourine, Mesnil and Rouget	678
The diagnosis of rabies, Forgeot and Nicolas	678
Elevation of body temperature through treatment of rabies, Remlinger	678
Treatment of rabies by means of radium rays, Tizzoni and Bongiovanni	679
Action of radium on rabies virus, Tizzoni and Bongiovanni	679
The transference of rabies virus to frogs, von Löte	679
Study of so-called infectious lymphosarcoma of dogs, Beebe and Ewing	679

	Page.
Membranous angina of a pseudo-diphtheritic nature in dogs, Ball	679
A new treatment of demodectic mange of dogs, Dupas	679
The virus of fowl plague, Landsteiner	680
Immunization against fowl cholera, Huntmüller	680
Chicken pox or sore head in poultry, Cary	680
A remedy for gapes in fowls	680
Contagious epithelioma of fowls, Burnet	681
Spirochæta in chickens, von Prowazek	681
Poultry parasites, Johnston	681
An epizootic outbreak of tapeworms in pheasants, Caparini	681

RURAL ENGINEERING.

Contributions to knowledge of irrigation in United States, Krüger	681
Proceedings of Fourteenth National Irrigation Congress, 1906	682
Closing break of Colorado River into Salton Sink, Cory	682
Raising of water by compressed air at Preesall, Lancashire	682
Brief notes on absorption losses on canals, etc., [Kennedy]	682
Earthen dams [Hill]	683
Land drainage, Whitson and Jones	684
Best value of Kutter's "N" to adopt in canal design, [Kennedy]	684
Industrial alcohol: Sources and manufacture, Wiley	684
Industrial alcohol: Uses and statistics, Wiley	685
Modern conveniences for the farm home, Wilson	685

RURAL ECONOMICS.

Cost of producing farm products, Hays and Parker	686
Condition of farm labor in California, Stafford and Eshleman	686
The land system of New Zealand, Smith	687
Advances to settlers, Smith	687
Indebtedness of peasant proprietors in Bavaria, Cohen	687
Manual of world economics, edited by von Halle	687
Crop Reporter	688
Agriculture in New Zealand, Murphy	688
Martinique and Guadelupe, Légiér	688
Agricultural statistics, 1906	688

AGRICULTURAL EDUCATION.

Federal legislation affecting agricultural colleges and experiment stations	689
A four-year college course in agriculture	689
The advancement of agricultural education, Wickson	689
Benefits of agricultural education, Burnett	689
Developing the American farm boy, Rankin	689
Rural education	689
Teaching agriculture in the common schools	690
The place of nature study and agriculture in our school system, Jewell	690
Progress of nature study in California, Davis	690

MISCELLANEOUS.

Nineteenth Annual Report of Illinois Station, 1906	691
Nineteenth Annual Report of Indiana Station, 1906	691
Twenty-fifth Annual Report of Ohio Station, 1906	691
Fifteenth Annual Report of Utah Station, 1904	691
Sixteenth Annual Report of Utah Station, 1905	691
Report of committee on experiment station organization and policy	691
Publications of Office of Experiment Stations	691
Press bulletins	691
Visitor's guide to [Ohio] station's work in 1906	691
Index for Bulletins 48-68 of the North Dakota Station	691

LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS REVIEWED.

<i>Stations in the United States.</i>		<i>Page.</i>
Alabama College Station:	Page.	
Bul. 136, Aug., 1906	680	
Alabama Tuskegee Station:		
Bul. 9, Nov., 1906	653	
Bul. 10., Dec., 1906	634	
California Station:		
Circ. 21, July, 1906	689	
Circ. 22, Aug., 1906	674	
Circ. 23, Aug., 1906	673	
Circ. 24	637	
Connecticut State Station:		
An. Rpt., 1906, pt. 1	618	
Hawaiian Sugar Planters' Station:		
Div. Ent. Bul. 2, Nov. 10, 1906	652	
Illinois Station:		
Circ. 105, Nov., 1906	607	
Nineteenth An. Rpt., 1906	691	
Indiana Station:		
Bul. 115, Dec., 1906	665	
Circ. 1, Oct., 1906	631	
Circ. 2, Nov., 1906	631	
Circ. 3, Dec., 1906	676	
Nineteenth An. Rpt., 1906	691	
Kansas Station:		
Bul. 140, Oct., 1906	671	
Louisiana Station:		
Bul. 89, Dec., 1906	677	
Maine Station:		
Bul. 131, Oct., 1906	657, 662	
Bul. 132, Nov., 1906	636	
Bul. 133, Nov., 1906	619	
Bul. 134, Dec., 1906	652	
Massachusetts Station:		
Met. Buls. 215-216, Nov.-Dec., 1906	612	
Minnesota Station:		
Bul. 97, Oct., 1906	686	
New Mexico Station:		
Bul. 59, May, 1906	611	
New York State Station:		
Bul. 281, Dec., 1906	653, 654	
North Dakota Station:		
Bul. 71, Oct., 1906	632	
Bul. 72, Nov., 1906	657	
Index Buls. 48-68, July 1, 1906	691	
Ohio Station:		
Bul. 174, Apr., 1906	633	
Bul. 175, May, 1906	627	
Bul. 176 (Twenty-fifth An. Rpt., 1906), June, 1906	612, 691	
Bul. 177, Aug., 1906	652	
Circ. 56, June 1, 1906	691	
Ohio Station—Continued.		
Circ. 57, Sept. 1, 1906	648	
Pennsylvania Station:		
Bul. 81, Nov., 1906	663	
Rhode Island Station:		
Bul. 114, June, 1906	619	
Bul. 115, July, 1906	619	
Bul. 116, Oct., 1906	631	
Bul. 117, Nov., 1906	619	
Texas Station:		
Bul. 78, Oct., 1905	667	
Bul. 79, Oct., 1905	631	
Bul. 80, Dec., 1905	637	
Bul. 81, Dec., 1905	630	
Bul. 82, Jan., 1906	615	
Bul. 83, Jan., 1906	617	
Utah Station:		
Fifteenth An. Rpt., 1904	691	
Sixteenth An. Rpt., 1905	691	
Wisconsin Station:		
Bul. 138, Aug., 1906	684	
<i>U. S. Department of Agriculture.</i>		
Farmers' Bul. 268	684	
Farmers' Bul. 269	685	
Farmers' Bul. 270	685	
Farmers' Bul. 271	627	
Farmers' Bul. 272	627	
Bureau of Entomology:		
Bul. 61 (25 cents)	655	
Bul. 62 (25 cents)	653	
Forest Service:		
Circ. 45	640	
Circ. 46	640	
Circ. 47	641	
Circ. 48	641	
Circ. 49	642	
Circ. 50	642	
Circ. 51	642	
Circ. 52	642	
Bureau of Statistics:		
Bul. 48 (15 cents)	686	
Crop Reporter, vol. 8, No. 8, Dec., 1906	688	
Weather Bureau:		
Bul. Q (\$10)	610	
Monthly Weather Review, vol. 34, Nos. 9-10, Sept.-Oct., 1906 (20 cents per number, \$2.50 per year)	611	
Office of Experiment Stations:		
Circ. 68	688	
Circ. 69	689	
Circ. 70	691	
Circ. 71	691	

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau requests and remittances should be directed to the Chief of the Bureau. The price of the Record is \$1 per volume, or 10 cents per number. The prices of other technical publications are given in the list above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XVIII.

MARCH, 1907.

No. 7.

Breeding as an art is perhaps as old as agriculture itself; certainly notable results were secured in the early ages. But efforts to put breeding on a scientific basis are very modern. The recent republication of Mendel's discoveries has given a great impetus to the systematic and thorough study of heredity and its practical bearings on animal and plant production, and there is now active and widespread interest in the subject of breeding in its scientific aspects.

In this country the movement is being fostered by the American Breeders' Association, whose purpose is stated in its constitution to be "to study the laws of breeding and to promote the improvement of plants and animals by the development of expert methods of breeding." This association was organized in 1904, and has held four regular meetings which were largely attended by the leading investigators and many practical breeders. The proceedings of the first three meetings have been published in two volumes, and comprise over one hundred and forty addresses and scientific papers relating for the most part to the theory of animal and plant breeding. A synopsis of the fourth meeting, recently held at Columbus, Ohio, is given elsewhere in this issue (p. 693). Taken together, these reports contain the best that is known in breeding, and furnish a basis for the revision of much that is contained in the treatises now used as text-books in the agricultural colleges.

The advantages of such an association in promoting and developing investigation in this important subject are very great. The subject is comparatively new as far as systematic investigation is concerned, and we have need of all the light that can come from associated effort and experience. The association has taken up the subject in a systematic manner, a large number of committees being authorized at the meeting in 1906 to look after various phases of animal and plant breeding. General problems were assigned to thirteen distinct committees, while fifteen others were to undertake the study of special problems relating directly to animal breeding, and a like number the problems of plant breeding. The membership of these committees includes some of the foremost investigators of the country.

Many of these committees have perfected their organization, accomplished considerable work of a preliminary nature, and are now actively engaged upon the duties assigned them, as indicated by the reports of progress presented at the recent meeting.

The present popularity of plant breeding is clearly evidenced by the large number of projects presented for investigation under the Adams fund. These probably exceed in number those proposed in any other single subject, but the wide range and grade of these undertakings indicate some misconceptions as to the research character of some of this work.

These projects may be classified somewhat roughly as follows: (1) Those which aim at "improvement" in a vague and indefinite way; (2) those which propose improvement and adaptation along rather more definite lines, through selections made from the crops in the field by eliminating the poorer groups rather than by isolating the superior individuals; (3) systematic breeding and selection, starting from the individual; (4) development of resistance to disease, insect attacks, hardiness, etc., by selecting individuals wherever found; (5) improvement through crossing and hybridizing, to be followed by systematic and rigorous selection; and (6) investigations into the laws of inheritance and variability, study of the correlations of vegetative parts with certain qualities, etc., to secure a basis for generalizations on the principles of breeding.

These classes evidently differ quite widely from a scientific standpoint and in the contribution they may be expected to make to our knowledge of breeding. The question is, Where should the line be drawn between the work of the plant breeder as an expert and investigator on the one hand and that of the seedsman and nurseryman on the other? There is a marked tendency among a certain class of men to regard the mere production of things, the general improvement of a plant or an animal in some respect, as research, wholly apart from any plan of adding to what we know about breeding and the laws governing it. These efforts consist in the adaptation of a plant to new environment, improving it in resistance to drought, earliness, productiveness, its composition with respect to some valuable constituent, and various qualities which go to make up excellence. Sometimes the plan does not even go so far as to designate the special line of improvement, and to this extent is aimless; and between this and the more specific and detailed plans of operations there are all gradations. Such work will usually not be along well-defined lines and methods, and unless it is carried out more carefully than the plan is outlined, it can be expected to add nothing of value to our methods.

Desirable as such work may be from a purely practical standpoint, it is difficult to see how it can be regarded as investigation in any true sense, and there is even doubt as to whether it is not more properly

the work of seedsmen and nurserymen than of an experiment station. Its real purpose is the attainment of material ends, the finding of something which is better, and it is not undertaken with a view to learning why certain results follow, and whether they are chance occurrences or in accordance with a general law and may serve as a safe basis of procedure. It is argued that we shall learn considerable from such work incidentally, but it seems very doubtful whether a man who is content to start out with a project which avowedly aims only at skillful improvement in an empirical way will often give himself much concern with incidental occurrences, whose study would delay him in his haste to attain a purely utilitarian end. Indeed, it may be questioned whether such work is often undertaken in the true scientific spirit.

It is the man who couples with his plan for improvement the purpose to add something to our knowledge, at least to the extent of knowing exactly how his end was attained, who will observe closely those specimens which do not come up to his requirements as well as those that do, will study the course of development carefully, and will thus learn something of the limitations and the idiosyncrasies of the supposed laws or rules.

Happily for the development of breeding as a science, a considerable number of projects have been undertaken which deal primarily or in part with the scientific aspects of the case. This is an encouraging tendency, and indicates something of a revolt from routine improvement work. More of the breeding work which now seems to be aimed at results without reference to the factors influencing their origin might be made to contribute toward the working out of certain principles if planned with reference to that end, and it seems extremely desirable that men who are engaged in this improvement work should take this feature into account.

Many have taken up breeding work without adequate preparation for it, and see in it only the possibility of "creating" something useful. Surely if anything more than the manipulative skill of the commercial breeder is claimed for this work, if it is to be regarded as appropriate for a station expert or an investigator, it should be undertaken with a full knowledge of the status of our information, so that advantage may be taken of the progress already made and of the most advanced thought in that field. Only in this way is the breeder equipped to observe intelligently and to correlate his observations in a way to be helpful.

One of the first requisites is accurate observation and the keeping of complete records. It is said that the only record of many new varieties is in the memory of the originator. The mere weeding out of those individuals which do not come up to the ideal standard, without any record as to their prevalence or characteristics, makes

the results useless for a study of inheritance and variability; but how important for this purpose might be a study of the reversions and the causes which lead to them.

Certain supposed limitations in plant breeding are so often mentioned that they have become almost axiomatic. Among these are the incompatibility of earliness and prolificacy, of large size and number of parts, and the correlation of other qualities. There is opportunity for further observation on these points, and if this limitation is found to prevail, the physiological phenomena which determine this antagonism remain to be worked out. Moreover, the recent work of Bateson has cast a doubt on the limitations of selection as a means of fixing a type which is worthy of further investigation.

The study of mutations, as described by De Vries, seems a fruitful field for investigation. The old taxonomic idea of the fixity of species appears to be doomed to give way to a different concept. MacDougal has recently shown that plants can be so profoundly affected by chemicals as to lose their character sufficiently to result in the production of new forms. If this should be true it may result in a new method of plant breeding, and at all events it calls attention to the possible influence of certain environmental conditions. Fertilizers and soil conditions are known to have an effect on the composition of the plant as well as on the quality. The turnip has been found to be quite constantly influenced in composition in proportion to the deficiency of the soil in phosphoric acid, and in the case of cereals an attempt has been made to work out a method for ascertaining the fertilizer requirements of the soil on the basis of the composition of the crop grown.

The necessity of taking these matters into account when plants are being bred for increased protein, and of fully checking or controlling all conditions other than individuality which may cause changes, will be apparent. In the case of leguminous plants bred for increased protein content the possible effect of nitrogen assimilation as a disturbing factor should be borne in mind. It has been shown that nitrogen assimilation may have the effect of increasing the nitrogen content of the plant or its seed, and it has also been found that plants apparently vary considerably in the energy with which they assimilate atmospheric nitrogen.

The conditions surrounding this activity and the factors which influence it are little understood, but these differences in conditions or capacity of the plant may nullify the results of breeding work which does not take account of them. The obvious remedy would seem to be the treatment of the soil in which these experiments are made in such way as to eliminate nitrogen assimilation and its attendant influences.

There is every reason why the breeding work as a whole should be placed upon a more scientific basis. It has become a prominent feature of the work of the stations, and the practical results attained have aroused interest and confidence in it. Already attention is being given by the more progressive farmers to selection, the use of improved seed, etc., and the work of the stations and others is therefore finding practical application in their hands. The greatest need of this work is improved methods and a better understanding of the principles involved, in order that observation may be guided and the interpretation of results made more sure.

With the retirement of Dean W. A. Henry from active service at the close of this year, the agricultural colleges and experiment stations will miss a very potent influence for development and an intelligent and enthusiastic advocate of their cause. For twenty-seven years Professor Henry has labored energetically and unceasingly for the recognition and upbuilding of agricultural education and experimentation, not only in his own State, but in a national way. His success has been an inspiration, and has gone a long way toward winning favor for agricultural instruction as well as pointing the way to reaching the farmers and their sons.

His career has characterized him as emphatically a man of action. All that he has achieved came through hard, persistent work. He believed in agricultural education and was determined to see its value recognized. If this could not be accomplished under the conventional method of teaching, he was ready to develop and test a new plan, and he had the courage of conviction necessary to carry it out in the face of doubt, if not opposition. And so he organized in 1886 the first successful short course in agriculture in this country; and when its success had been demonstrated he established the first dairy school in America in 1890. Four years later he started the ten-day course for adult farmers, which attracted one hundred and seventy-five men the first year, and was attended this year by six hundred and seven farmers.

He took a personal, individual interest in the students of these courses. He made special effort to follow their subsequent careers in order to study the benefits of the courses and means of strengthening them, and the success of these young men in a business way, as leaders in their communities, or in teaching, was a matter of the keenest gratification to him. In a very large measure the short course in agriculture is an institution of his making, and in later years he has turned his attention to the development of the long course and post-graduate work. He also interested himself in agricultural instruction through secondary schools, and had a part in the establishment of agricultural high schools in Wisconsin.

Professor Henry's success was no less marked in the development of the experiment station. He went to the University of Wisconsin in 1880 as professor of botany and agriculture, and three years later secured funds for the establishment of the experiment station. He had a thorough appreciation of scientific work and was keenly alive to the needs of the farmer. Step by step he developed different departments of the work, gathering around him a competent corps of workers, who were inspired by his enthusiasm and aided by his intelligent insight into the practical and scientific bearing of their work. Under his direction the Wisconsin Station has placed to its credit some of the most noteworthy contributions to the science of agriculture, and a multitude of results of practical importance, which the institution has carried directly to the farmer.

The imposing array of buildings which he has brought together at the University of Wisconsin, several of them the first of their kind to be erected at any agricultural college, will remain a tribute to his long period of service and to the confidence he inspired in the people of his State. Although not yet fifty-seven years of age, his health has been impaired by constant devotion to his work, which left little time for vacation. The letters of President Van Hise and of the board of regents in accepting the resignation, which he had been prevailed upon to postpone for some time, expressed a profound appreciation of Professor Henry's services to the university and to the State, and a deep sense of personal loss at his going. The title of "emeritus professor" was conferred upon him.

In the closing paragraph of his letter Professor Henry says: "My work has been that of a pioneer. I have laid only the foundations; others will build a better superstructure than I possibly could . . . It is my hope, as it is my ambition, that when the load of responsibility is removed and I have somewhat regained my old-time health and vigor I can draw closer than ever before to our students and the farmers, and so in some ways at least be more useful than ever before." His many friends the country over will echo this hope, and will wish for him many years of continued activity in a less responsible and exacting capacity as a reward for his great service.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

Principles and practice of agricultural analysis, H. W. WILEY (*Easton, Pa.: The Chemical Pub. Co., 1906, vol. 1, 2. ed., rev. and enl., pp. XII+636, pls. 18, figs. 55*).—It is stated in the preface that "so rapid has been the advance of agricultural science that in the preparation of the second edition of this volume it has been found necessary to practically rewrite it. A considerable part of the contents of the first edition of this volume relating as much, if not more, to fertilizers than to soils, has been transferred to the second volume, but new matter more than equivalent thereto in bulk has been inserted. The latest improved methods have been described, in so far as they are based on new principles or have secured better results. An attempt has been made to bring out more fully the principles of procedure involved in order that the present volume might not only mirror the latest advances in science, but also, to some extent, reflect the philosophy of method and practice. To this end, many of the older methods, long out of vogue, are retained, because in them are found the beginnings of fundamental procedures which serve to unify the processes of analysis and render more intelligible the modern methods."

The bacteriological method in chemical research, W. OMELIANSKI (*Arch. Sci. Biol. [St. Petersb.], 12 (1906), No. 3, pp. 224-247*).—Reviewing the rapid progress which has recently been made in bacteriological investigation, the author suggests that in view of the intimate relation which exists between bacteriological and chemical reactions it is time that this alliance was realized in the establishment of a science of micro-biological chemistry similar to physiological chemistry, technical chemistry, etc. He points out that heretofore the bacteriological method has been used to study almost exclusively the natural processes of transformation of matter notwithstanding the fact that it has enriched chemistry by a series of perfectly new reactions and transformations. He is convinced that the sciences of chemistry and bacteriology should be united and that both will be advanced thereby, chemistry by being furnished with a new source of reagents and reactions, and bacteriology by having the aid of chemistry in solving a large number of very complicated chemical problems.

The duty of chemistry to agriculture, C. G. HOPKINS (*Illinois Sta. Circ. 105, pp. 27*).—This is the address of the president of the Association of Official Agricultural Chemists delivered at the annual convention at Washington, D. C., November 8, 1906.

On chemical examinations of arable soils, C. G. EGGERTZ (*Meddel. K. Landtbr. Akad. Exptlfält. [Stockholm], 1906, No. 91, pp. 1-62; K. Landtbr. Akad. Handl. och Tidskr., 45 (1906), No. 3-4, pp. 177-236; abs. in Centbl. Agr. Chem., 35 (1906), No. 12, pp. 793-799*).—The author gives a general discussion of methods of soil analysis and considers at some length the appearance and importance to plants of the various mineral constituents of the soils.

The method of analysis of solutions obtained by means of strong acids is severely criticised, the following method being used in the author's investigations here reported: At least 1 kg. of the soil in its natural condition, calculated on a water-free basis, is shaken for an hour with 2 liters of a 2 per cent hydrochloric-acid solution in a rotary apparatus of similar construction as, but of larger dimensions than, the Wagner apparatus for determination of citrate-soluble phosphoric acid in Thomas phosphate, and 1 liter filtered off. This amount is then evaporated to dryness to separate out silica and the ordinary course of analysis followed for the determination of the other constituents. Nitric acid is determined in a separate sample which is digested with water and the filtrate examined by the Ulsch method. Ammonia is determined in a sample digested with water acidulated with sulphuric acid. Organic nitrogen is determined according to the Kjeldahl method.

It was found that soils treated with a 4 per cent, and even a 2 per cent, hydrochloric-acid solution become sterile for the time being for all crops experimented with except potatoes, which can make a sickly growth therein. The reason why barley, at least, does not find sufficient food in the soil extracted in this manner is that soil so treated contains too little lime. During the second to fourth year after extraction, potatoes, oats, and barley develop much more luxuriantly in extracted soil than in a good arable soil, the explanation given being that the available plant food the first year is removed by the acid digestion and subsequent washing with water, whereas new plant food is formed later on from the organic raw material which remained in the soil. The nitric and sulphuric acids in the soil, in the author's opinion, are obtained from organic material, and phosphoric acid from phosphorus in humus substances.—
F. W. WOLL.

Quantitative determination of potassium, R. PAJETTA (*Gaz. Chim. Ital.*, 36 (1906), II, pp. 150–156; *abs. in Jour. Soc. Chem. Indus.*, 25 (1906), No. 21, p. 1068).—The author finds that Tarugi's persulphate method of determining potash is inaccurate on account of the solubility of the potassium persulphate in solutions of sodium sulphate.

The solubility of gypsum in phosphoric acid solutions, W. C. TABER (*Jour. Phys. Chem.*, 10 (1906), p. 593; *abs. in Chem. Abs.*, 1 (1907), No. 1, p. 21).—It was found that at a temperature of 25° the solubility of gypsum increased with the concentration of the phosphoric-acid solution until a maximum was reached at about 230 gm. of phosphorus pentoxid per liter, when the solubility was about four times that in pure water. Beyond this point the solubility regularly decreased with the increase of the acid content.

The detection of nitric and nitrous acids, H. W. WAGNER (*Pharm. Centralblatt*, 48 (1907), No. 1, pp. 5–7).—The thymol, resorcin, and especially the phenol reactions for these acids are described.

Nitron: A new reagent for nitric acid (*Merck's Ann. Rpts.*, 19 (1905), pp. 151, 152; *abs. in Chem. News*, 94 (1906), No. 2454, p. 271).—A description is given of the composition, properties, and method of use of this reagent. (See also *E. S. R.*, 16, p. 945.)

Determination of nitrates, F. S. SINNATT (*Proc. Chem. Soc. London*, 22 (1906), p. 255; *abs. in Analyst*, 31 (1906), No. 369, p. 418; *Jour. Soc. Chem. Indus.*, 25 (1906), No. 24, p. 1227; *Chem. Abs.*, 1 (1907), No. 2, p. 149).—Knecht and Hibbert's method for picric acid was applied to the determination of potassium nitrate with a fair degree of accuracy. The method depends on the conversion of the nitrates into picric acid by means of phenolsulphonic acid, the picric acid being determined by titanium trichlorid.

On the distillation of ammonia with and without condensing in the Kjeldahl method of determining nitrogen, E. PESCHECK (*Jour. Landw.*, 54

(1906), No. 4, pp. 367-384).—This article reports a number of studies of factors determining the accuracy of this method, especially the solubility of the alkalis of the glass apparatus and loss of ammonia. With Jena glass apparatus there was no considerable error due to solubility of alkalis of the glass. By use of proper precautions the loss of ammonia need not be considerable, although it can not be entirely prevented in distillation without cooling. In general, however, the method of distillation without a condenser gave substantially the same results as in case of the use of a condenser.

The determination of ammonia in water by Nessler's reagent, A. BENSON (*Compt. Rend. Acad. Sci. [Paris]*, 143 (1906), No. 5, pp. 289-291; *abs. in Bul. Soc. Chim. Paris*, 3, ser., 35 (1906), No. 24, p. 1320).—According to the author's investigations the precipitate obtained with Nessler's solution in weak solutions of ammonia (6 mg. per liter) has the following formula: $\text{Hg}_9\text{N}_4\text{I}_6$, a brown amorphous body insoluble in neutral solvents, but soluble in potassium iodid, which in excess liberates all the nitrogen in the form of ammonia as follows: $\text{Hg}_9\text{N}_4\text{I}_6 + 12\text{KI} + 12\text{H}_2\text{O} = 9\text{HgI}_2 + 4\text{NH}_3 + 12\text{KOH}$. All of the ammonia is not precipitated, the proportion being determined by various conditions of temperature, dilution, preparation of reagents, etc. In the author's experiments as much as 21 per cent of the ammonia escaped precipitation.

The Volhard method for the determination of chlorin in potable waters, F. T. SHUTT and H. W. CHARLTON (*Trans. Roy. Soc. Canada*, 2, ser., 11 (1905-6), Sec. III, pp. 67-71; *abs. in Chem. News*, 94 (1906), No. 2453, pp. 258-260).—Comparisons of the Volhard and chromate methods on a large number of samples of water are reported, the results showing that the Volhard method while less rapid than the chromate is more satisfactory for waters containing very small amounts of chlorin.

Table of the principal physical and chemical constants of fats, D. SIDERSKY (*Indus. Lait. [Paris]*, 31 (1906), No. 48, pp. 775, 776).—Constants for 28 fats and oils of animal and vegetable origin calculated from compiled data are reported in tabular form.

A new method for the determination of casein in cheese, A. TRILLAT and SAUTON (*Bul. Soc. Chim. Paris*, 3, ser., 35-36 (1906), No. 23, pp. 1207-1210).—This is a direct method for the determination of casein in cheese, based upon the same principle as the method for the determination of casein in milk previously noted (E. S. R., 18, p. 9). The method is believed to show accurately the amount of proteids in cheese which have not undergone transformation during the process of ripening.

In applying the method to commercial samples, the following percentages of casein were obtained: Camembert, 18.20; Gruyère, 31.34; Gervais, 6.42; Brie, 22.93; Roquefort (half ripened), 11.65; Roquefort (well ripened), 7.10; and Holland, 31.50.

The classification of animal and vegetable proteids in relation to their products of decomposition, J. H. MILLAR (*Trans. Guinness Research Lab.*, 1 (1906), pt. 2, pp. 149-166).—A summary and discussion of data with a view to classification of proteids.

Concerning glutamins, E. SCHULZE (*Landw. Vers. Stat.*, 65 (1906), No. 3-4, pp. 237-246).—The author notes that there is considerable variation in the reported measurements of the optical activity of glutamin. A number of such measurements made with glutamins of known origin are reported and compared with the author's earlier work and with that of other investigators. In his opinion, it is not improbable that the variations are due to the existence of glutamins in stereoisometric forms.

On the liberation of phosphorus from nuclein compounds, F. H. SCOTT (*Brit. Med. Jour.*, 1906, No. 2399, pp. 1791, 1792).—In a paper presented at the Toronto meeting of the British Medical Association (1906), the author reports studies of the phosphorus in nuclein compounds. As a whole his investigation shows "that it is much more difficult to cause the phosphorus to pass from its nucleic-acid combination to an inorganic condition than was previously supposed. The whole principle of the Lilienfeld-Monti-Macallum reaction is therefore wrong, and we must conclude, with Raciborski and Bensley, that the deductions drawn from its use are worthless in so far as they relate to nucleic acid."

On the effect of the volume of the lead precipitate in cane sugar analysis, N. DEERR (*Internat. Sugar Jour.*, 9 (1907), No. 97, pp. 13-15).—The following conclusions are drawn from the results of experiments:

"Solutions of cane products when made up to different volumes in the presence of the lead precipitate tend to give nearly identical polarizations, when the readings are made at different concentrations.

"This effect is due to the compensating effect of the volume occupied by the lead precipitate and the increase in specific rotation with dilution.

"The lead precipitate has an effect on the polarization, and neglect of this tends to give a plus error to observations made under the conventional method of analysis."

The chemical composition of the crude fiber of sugar cane, H. C. P. GEERLIGS (*Meded. Proefstat. Suikerrict West-Java*, 1906, No. 91, pp. 20).—The crude fiber portion of a number of samples of sugar cane of different varieties was studied and its constituents determined.

The furfural and methylfurfural-yielding constituents of lignocellulose, K. FROMHERZ (*Ztschr. Physiol. Chem.*, 50 (1906), No. 2-3, pp. 209-240, pl. 1).—The investigations which were made with the lignocellulose of aspen wood are a contribution to the chemistry of cellulose.

Determination of mineral acids in vinegar, F. W. RICHARDSON and J. L. BOWEN (*Jour. Soc. Chem. Indus.*, 25 (1906), No. 17, pp. 836-838).—A modification is described of the Hehner method of estimating sulphuric acid in vinegar, which the authors claim increases decidedly the accuracy of the results.

The fuller's earth test for caramel in vinegar, W. L. DUBOIS (*Jour. Amer. Chem. Soc.*, 29 (1907), No. 1, pp. 75-77).—Such great variations were obtained in tests of fuller's earth of different sorts for removing coloring matter from samples of cider vinegar of known purity that the author believes the material should not be employed in analytical work for removing coloring matter except in preliminary tests.

METEOROLOGY—WATER.

Climatology of the United States, A. J. HENRY (*U. S. Dept. Agr., Weather Bur. Bul. Q.*, pp. 1012, pls. 33, figs. 7).—The primary object of this work is stated to be "to present in form for easy reference comparative climatic statistics for the different portions of the United States. The need of such a volume has been felt for some time, particularly within the Department."

In general the statistics presented cover the period from 1870 to 1903. "Two distinct series of observations have been used: First, the observations made primarily for the synoptic weather charts during the period 1870 to 1903; second, the observations made by voluntary observers of the U. S. Weather Bureau for purely climatic purposes. . . .

"The first chapter deals with the broader features of the climate of the United States. It is intended to be read in connection with reports on the climate of the respective States, which appear in subsequent chapters. For convenience in

grouping and discussion the country has been divided into six climatic districts, viz, the New England and Middle Atlantic States, the South Atlantic and East Gulf States, the West Gulf and Southern Rocky Mountain Slope, the North Central States, the Rocky Mountain and Plateau region, and the Pacific coast."

Data regarding location, equipment, and climate are summarized for each station in these districts.

Forty years of southern New Mexico climate, J. D. TINSLEY (*New Mexico Sta. Bul.* 59, pp. 43, figs. 5, dgrams. 4).—"This bulletin contains a record of the monthly and annual mean maximum, mean minimum, and mean temperatures, highest and lowest temperatures during each month, number of days with temperature of 32° or less, number of days with temperature of 60° or less, precipitation, relative humidity, condition of the sky, and wind movement for each month and year from 1892 to 1905, as observed at the New Mexico Experiment Station. Also, temperature and rainfall records for other stations in the Mesilla Valley for most of the years between 1851 and 1890.

"The data have a general application to those portions of southern New Mexico having an altitude less than 4,000 ft.

"The annual mean maximum temperature for 14 years is 76.8°. The annual mean minimum for 13 years is 41.4° and the annual mean for 40 years is 61.6°. The lowest temperature in 14 years was 1° in December, 1895, and the highest, 106°, which has occurred several times. Temperatures of 10° and less are not uncommon at night in December, January, and February.

"The mean annual range of temperature is 35.4°. The absolute monthly range is from 45° to 75°. The greatest annual range was 101° in 1895.

"The mean number of days in a year when the temperature does not rise above 60° is 56 and of the days when the temperature falls below 32° in the 24 hours is 121.

"The mean annual rainfall is 8.8 in. The smallest was 3.5 in. in 1873, and the largest, 17.1 in. in 1905. The most of the rain falls during July, August, and September. Snow occurs, but the amount is too small to be of economic importance.

"The records scarcely sustain the idea that there has been a permanent increase in the rainfall.

"The relative humidity is low, the annual mean being probably about 40 per cent. The mean monthly wind movement is about 5,000 miles, 7 miles an hour. The mean number of clear days per year is 225, part cloudy 91, and cloudy 49. The evaporation is 5 to 6 ft. per year."

World weather, J. ELIOT (*Sci. Amer. Sup.*, 62 (1906), No. 161½, pp. 25862, 25863).—"This is a quotation of a review of a memoir by this author, in which the belief is expressed that the results of investigations reported in the memoir have an important bearing on the practical work of forecasting. The statement is made that the investigations are of special importance because novel methods of studying air movement on a large scale were employed, "leading to results not merely unexpected, but opposed to the fundamental principles which have formed the chief stock-in-trade of meteorologists during the past fifty years."

Monthly Weather Review (*Mo. Weather Rev.*, 3¼ (1906), Nos. 9, pp. 405-452, figs. 9, charts 7; 10, pp. 453-504, figs. 7, charts 7).—"In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of September and October, 1906, monthly review of the progress of climatology throughout the world, recent papers bearing on meteorology, recent additions to the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 9.—The Relation of the Weather to the Flow of Streams, by F. H. Brandenburg; Phenomenal Rainfall at Guinea, Va. (illus.), by E. A. Evans; The

Green Sun of the Krakatoa Eruption; International Weather Cablegrams; The Zodiacal Light, by A. Searle; The Direction of Local Winds as Affected by Contiguous Areas of Land and Water, by T. H. Davis; Height of the Atmosphere Determined from the Time of Disappearance of Blue Color of the Sky after Sunset, by T. J. J. See; Pilot Balloons and the Upper Winds, by F. O. Hills; Professor Adolf Erman, by W. Erman; The Atmosphere and the Soil; The Classification of Climates; The West Indian Hurricanes of September, 1906 (illus.), by E. B. Garriott; Weather Bureau Men as Educators; Educational Notes; and Popular Meteorological Lectures in England.

No. 10.—Suggestions as to Teaching the Science of the Weather, by J. W. Smith; Abnormal Weather Over Southern Texas, by J. L. Cline; A Rare Cumulus Cloud of Lenticular Form (illus.), by H. H. Clayton; Do Climates Change? Climatological Data for Virginia; Land and Sea Winds; Reprints of Works on Meteorology; Premature Publication; Sonora Storms and Sonora Clouds of California (illus.), by A. Campbell; Has the Gulf Stream any Influence on the Weather of New York City? On the Formation of Anchor Ice, or Ground Ice, at the Bottom of Running Water, by H. T. Barnes; Weather Bureau Men as Educators; and Studies on the Thermodynamics of the Atmosphere—VIII. The Meteorological Conditions Associated with the Cottage City Waterspout—Continued (illus.), by F. H. Bigelow.

Meteorological observations, J. E. OSTRANDER and T. A. BARRY (*Massachusetts Sta. Mct. Buls.* 215, 216, pp. 4 each).—Summaries of observations on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during November and December, 1906. The general character of the weather of each month is briefly discussed, and the December bulletin gives a summary for the year. The principal data in this summary are as follows:

Pressure^a (inches).—Maximum, 30.95, February 11; minimum, 29.25, January 4; mean, 30.051. *Air temperature*^b (degrees F.).—Maximum, 91, September 18; minimum, -7.5, March 24; mean, 47.3. *Humidity*.—Mean dew-point, 38.6; mean relative humidity, 77.1. *Precipitation*.—Total rainfall or melted snow, 45.45 in.; number of days on which 0.01 in. or more rain or melted snow fell, 121; total snowfall, 56½ in. *Weather*.—Total cloudiness recorded by sun thermometer, 1,794 hours, or 40 per cent; number of clear days, 130. *Bright sunshine*.—Number of hours recorded, 2,660, or 60 per cent. *Wind*.—Prevailing direction, west, northwest; total movement, 53,273 miles; maximum daily movement, 572 miles, February 28; minimum daily movement, 1 mile, February 14 and May 6; maximum pressure per square foot, 12 lbs., December 1, NNW. *Dates of frost*.—Last, May 20; first, September 25. *Dates of snow*.—Last, April 23; first, November 11.

Meteorological summary for 1905, C. A. PATTON (*Ohio Sta. Bul.* 176, pp. 385-399).—This summary includes as usual notes on the weather of each month and tabulated daily and monthly records of observations, at the station at Wooster, Ohio, on temperature, precipitation, cloudiness, direction of the wind, etc., and for comparison, similar data for 18 previous years (1888-1905) at the station and for 23 years (1883-1905) in other parts of the State.

The mean temperature for the year at the station was 49° F.; for the State 50°; the highest temperature at the station 92°, July 17; for the State 100°, July 10; the lowest temperature at the station -12°, February 14; for the State -20°, February 3. The annual rainfall at the station was 24.93 in., for the State 39.02 in. The number of rainy days was 118 for both the station and

^a Reduced to freezing and sea level. ^b In ground shelter.

the State at large. The prevailing direction of the wind was south at the station and southwest for the State. The most marked feature of this meteorological record is the deficiency of rainfall at the station in 1905, namely, 24.93 in. as compared with 38.9 as the average for 48 years. In contrast with this deficiency at the station is an average rainfall during 1905 of 39.02 in. for the State as compared with an average of 37.25 in. for 23 years.

Peruvian meteorology, 1892-1895, S. I. BAILEY (*Ann. Astron. Observ. Harvard Col.*, 39 (1906), pl. 2, pp. 155-286, pls. 4, figs 2; *abs. in Science*, n. ser., 24 (1906), No. 624, p. 785).—Observations on temperature, pressure, precipitation, wind movement, cloudiness, etc., at 9 stations varying in altitude from 80 to 19,200 ft. are summarized.

Meteorology, E. J. VON DAELSZEN (*New Zeal. Off. Yearbook 1906*, pp. 200-206).—Monthly summaries are given of observations on temperature, rainfall, atmospheric pressure, and wind, throughout New Zealand at 12 stations during the year 1905.

Weather observation, A. MARTIN (*Queensland Agr. Jour.*, 17 (1906), No. 5, pp. 223-225).—The importance of the farmer being a careful observer of weather conditions is pointed out and some simple rules for predicting weather are given.

The meteorological service of the Republic of Mexico, M. E. PASTRANA (*Bol. Sec. Fomento [Mexico]*, 6 (1906), No. 2, 11, pp. 15-35).—The history of the development and organization of this service, showing not only its present organization but its proposed extension, is discussed in this article by the director of the service.

Résumé of researches in the higher meteorology, F. H. BIGELOW (*George Washington Univ. Bul.*, 5 (1906), No. 4, pp. 23-35).—The author briefly summarizes the present status of investigations which he has been carrying on for a number of years "to throw light upon the relations between the amount of the variable energy emitted by the sun and the corresponding changes in the circulation of the earth's atmosphere," the general features of this research being outlined under three heads, namely, "(1) the solar-terrestrial electric and magnetic fields, (2) the circulations of the atmospheres of the sun and of the earth, respectively, and their mutual relations, (3) the reconstruction of the observational data."

Storms and hail, E. DAGUILLON-PIJOL (*Jour. Agr. Prat. Vit. et Écon. Rurale Midi France*, 102 (1906), No. 6, pp. 227-239).—This is mainly a review of past experience in hail protection by means of cannonading, from which the conclusion is drawn that, if the organizations for hail protection will continue their trials and science will persist in its researches, very probably a time will come when agriculturists may be protected against hail.

Thunderstorms and the moon, C. W. HISSINK (*Hemel en Dampkring*, 4 (1906), No. 5, pp. 78, 79; *abs. in Science*, n. ser., 24 (1906), No. 626, p. 866).—This article reports a study of thunderstorm days in Holland for the period 1883 to 1903, showing so complete an agreement for different phases of the moon as to indicate a lunar influence on storms.

The sanitation of air, K. MEIER (*Pop. Sci. Mo.*, 70 (1907), No. 1, pp. 19-32).—This article discusses the bearing of exhausted and contaminated air on health; the causes of impure air, including smoke, street dust, vitiation through heating, cooling, and ventilating apparatus, and various other causes in buildings, and vitiation through animal life; and suggestions for relief, including improvements in sanitation, ventilation, and construction of buildings.

It is stated that the subject of the sanitation of air has been much neglected and as a result conditions still exist which might be greatly improved with com-

parative ease. Two of the chief causes of impure air in cities are smoke and street dust. The former can be greatly reduced by the elimination of steam-power transportation in urban and densely populated districts, which is asserted to be entirely unnecessary and should have long ago been prohibited. It is also asserted that the accumulation of street dust is inexcusable from the hygienic standpoint. The heating appliances now in general use are in many cases objectionable because they collect dust and disseminate it throughout the air in houses. Conditions in houses can be improved by seeing that all stoves and grates are connected with flues. The author is of the opinion that in general it is better to secure ventilation by natural means rather than by use of forced or mechanical ventilation.

The life history of surface air currents: A study of the surface trajectories of moving air, W. N. SHAW and R. G. K. LEMPFORT (*London: Wyman & Sons, 1906, pp. 107, pls. 26, figs. 20*).—The paths or trajectories of storms are worked out and platted from records of the air movement at a large number of stations in the area passed over by a series of typical storms, and the bearing of the results thus obtained on the movement of air into or out of storm areas and on the associated weather conditions is discussed.

Progress in the field of water investigation, L. KRAUSS (*Apoth. Ztg., 21 (1906), p. 846; abs. in Chem. Ztg., 30 (1906), No. 93, Repert. No. 46, p. 403*).

Springs in limestone regions and their quality for drinking purposes, H. SCHARDT (*Bul. Soc. Neuchâtel. Sci. Nat., 32 (1903-4), pp. 221-242*).—This is one of the reports provided for at the Thirteenth International Congress of Hygiene and Demography at Brussels in 1903, and discusses somewhat elaborately the conditions affecting the drinking quality of waters from limestone areas. The danger of imperfect filtration on account of fissures and underground channels is very clearly brought out and a strict examination and control of waters of this kind is shown to be an urgent necessity in order to insure their purity and safety.

Contribution concerning the purification of water by ozone, D. RIVAS (*Centbl. Bakt. [etc.] 2. Abt., 17 (1906), No. 14-16, pp. 506-517, figs. 6*).—The preparation of ozone by means of electrical discharges is described and experiments in Philadelphia in which the process was applied in the purification of water are reported.

The results lead to the conclusion that under favorable conditions ozone not only reduces the general bacteria content of water but also eliminates *Bacillus coli communis*. It also attacks objectionable organic matter in the water and oxidizes ammonia to nitrate. In water rich in organic matter, however, the germicidal and chemical action is only partial. With such water as is ordinarily obtainable for a city supply it is believed that very satisfactory results would be obtained by ozonization.

Control of water purification plants, VON COCHENHAUSEN (*Ztschr. Angew. Chem., 19 (1906), Nos. 48, pp. 1987-1993; 49, pp. 2023, 2024*).—A discussion of processes for removing lime and magnesia from water, and methods of determining combined carbon dioxide, lime, magnesia, and hardness in connection with purification plants.

A sand filter for the home, R. FLETCHER (*N. H. Sanit. Bul., 2 (1906), pp. 190-198; abs. in Chem. Abs., 1 (1907), No. 1, p. 77*).—The making and use of such a filter for purification of water for home use are discussed. The capacity of the filter described is about 40 gal. per day.

SOILS—FERTILIZERS.

A treatise on rocks, rock-weathering, and soils, G. P. MERRILL (*New York and London: The Macmillan Co., 1906, rev. ed., pp. XXI+400, pls. 31, figs. 42*).—The author states that in the preparation of this revised edition "many errors have been corrected, matter that proved nonessential eliminated, and a considerable number of new analyses and illustrations introduced."

Studies on the soils of the northern portion of the Great Plains region: The third steppe, F. J. ALWAY and R. A. GORTNER (*Amer. Chem. Jour., 37 (1907), No. 1, pp. 1-7*).—This is a continuation of studies previously noted (*E. S. R., 18, p. 531*) and deals with the region extending "from the Missouri Coteau westward to the Rocky Mountains or the bordering foothills, including the portions of Alberta and western Saskatchewan south of the North Saskatchewan River." The altitude of this region varies from about 2,000 ft. on the east to over 4,000 ft. at the foot of the mountains.

The soil is in general more sandy and gravelly than that of the second steppe, studies of which were reported in the previous article. "The surface soils are rich in nitrogen, potash, and lime, and are well provided with phosphoric acid. The subsoil differs in mineral constituents from the preceding chiefly in the much larger amount of calcium and magnesium carbonates and in a somewhat smaller amount of potash. Both contain considerable quantities of water-soluble salts, which in many places over the area have been partly leached out into the depressions, forming tracts of alkali lands."

Analyses of samples from each foot of the soil to a depth of 6 ft. are reported as well as of the water of Old Wives Lake, which is situated near the eastern edge of the steppe and serves as an evaporating basin for the drainage of a region covering about 5,000 square miles. Analysis of the lake water showed the presence of 27.3 gm. of solid matter per liter, the principal constituents being sodium, sulphuric acid, and chlorine, indicating that the principal salt present is sodium sulphate, with smaller amounts of sodium chloride.

Attention is called to the fact that glass objects which have been exposed for some time to direct sunshine on the soils of this region assume a more or less intense violet coloration. It was thought that this might be due to the rather large proportion of manganese occurring in the soil, but further investigation indicated that it resulted from the presence of manganese in the glass itself.

Maintaining the fertility of rice soils—a chemical study, G. S. FRAPS (*Texas Sta. Bul. 82, pp. 42, figs. 4*).—This bulletin reports a study of the chemical composition and properties of some rice soils, rice irrigation waters, and of the rice plant itself, with the object of suggesting methods for maintaining the fertility of rice soils.

From the analyses reported it is estimated that an average Texas rice crop (producing 1,900 lbs. of rough rice per acre) requires 16 lbs. of phosphoric acid, 42 lbs. of nitrogen, and 55 lbs. of potash. Rice straw carries with it when removed 3 lbs. of phosphoric acid, 14 lbs. of nitrogen, and 31 lbs. of potash per acre. In burning rice stubble nearly 5 lbs. of nitrogen is lost and in burning rice straw 14 lbs. of nitrogen passes off. The ashes of the straw contain 3 lbs. of phosphoric acid and 37 lbs. of potash per acre.

"An average crop of rice consumes more nitrogen than an average crop of cotton, oats, or corn. If the rice straw is taken entirely away, the draft on the potash is four times as much as by cotton, oats, or corn. If the rice straw ashes are restored, the loss of potash is 5 lbs. per acre, about half as much as is removed by cotton, oats, or corn.

"On an average, 7.6 lbs. phosphoric acid, 1.4 lbs. nitrogen, and 23.4 lbs.

potash per acre are brought on the field by the irrigation water. This is not as much phosphoric acid, nitrogen, or potash as is consumed by a crop of rice. It is estimated that the seepage and off-flow waters carry off approximately 4.5 lbs. phosphoric acid, 3.4 lbs. potash, and probably larger amounts of nitrogen.

"The net result of the irrigation waters is thus an average gain of 3.1 lbs. phosphoric acid and 20 lbs. potash per acre, and a loss of nitrogen. A loss of approximately 20 lbs. nitrogen per acre by percolation during the winter may take place, with small amounts of potash and phosphoric acid.

"The soil loses, in the growth of an irrigated rice crop, on an average of 12 lbs. phosphoric acid, 60 lbs. of nitrogen, and 22 lbs. potash per acre, if the straw is removed and the stubble burned. If, however, the stubble is plowed under, and the straw ashes returned to the field they come from, there is an average loss of 9 lbs. phosphoric acid, 57 lbs. nitrogen, and apparently a gain of 15 lbs. of potash."

Of the soils examined those of Jefferson, Orange, De Witt, and Victoria counties, as well as the black soils of Brazoria, contained small quantities of phosphoric acid. Those of Harris County, the Rio Grande Valley, and the Brazos bottom soils of Brazoria contained an abundance of phosphoric acid. Orange County soil was low in potash, the others contained a moderate amount, while the Rio Grande Valley soil was rich in this constituent. The only soil low in lime was that of Orange County.

Nitrification studies indicate that the soils of Orange and Brazoria counties are too low in phosphoric acid for efficient nitrification. All the soils examined contained very small amounts of chemically available phosphoric acid as measured by fifth-normal nitric acid. The chemically available potash determined in the same way was low in the Brazoria and Orange county soils, but present in moderate amounts in other soils.

Regarding the treatment of rice soils, the author states that "burning the straw is wasteful, but if burned, the ashes should be scattered on the field from whence they came. The stubble should be plowed under if possible. The nitrogen content of the soil should be maintained by growing leguminous crops (cowpeas, vetch, etc.), which are plowed under with caution, grazed off, or made into hay."

Results of analyses of cultivated soils, F. F. VILLASEÑOR (*Mem. y Rev. Soc. Cient. "Antonio Alzate,"* 23 (1905), No. 5-6, pp. 187-198; (1906), No. 7-12, pp. 389-394).—Physical and chemical analyses of 9 samples of Mexican soils are tabulated.

A note on the protective action of colloids on suspended clay and natural clay soils, E. FICKENDEY and B. TOLLENS (*Jour. Landw.,* 54 (1906), No. 4, pp. 343-350).—This article discusses the results of experiments in which 20 cc. of solutions of different colloids of varying concentrations was mixed with 1 cc. of kaolin suspension and twice-normal electrolytes of different kinds (potassium hydroxid, hydrochloric acid, etc.) were added. It was found that in such cases starch exerted no influence, but that tannin produced a marked effect in preventing flocculation (but only in alkaline solution), while the amphoteric gelatin exerted a positive influence in acid solutions and a negative influence in alkaline solutions. The greatest protective action was observed with about $\frac{1}{100}$ -normal hydrochloric acid containing from 0.1 to 0.2 gm. of gelatin per liter.

The beneficial effect of lime on the structure of soils is explained on the basis of these results as due to the fact that lime forms insoluble compounds with the humus acids and that these compounds remain insoluble in spite of the alkaline reaction of the soil. It is claimed that the calcium ion is especially active in flocculations and that the flocculating power of ions bears a direct relation to their precipitation reactions.

The injurious effect of sodium nitrate on soil structure noted by Krüger (E. S. R., 17, p. 949) is ascribed to the fact that the sodium carbonate formed in the soil dissolves humus acids and interferes with the flocculation of clay particles.

An explanation of the physical terms used in the article is given by B. Tollens.

On the nitrogen compounds in cultivated soils, T. PFEIFFER and P. EHRENBERG (*Mitt. Landw. Inst. Breslau*, 3 (1906), No. 5, pp. 899-927; *abs. in Chem. Centbl.*, 1906, II, No. 21, pp. 1624, 1625; *Chem. Ztg.*, 30 (1906), No. 93, *Reperit.* No. 46, pp. 402).—Parallel determinations of nitrogen by the two authors in 5 different types of soil before and after drying with and without addition of acid are reported and discussed with special reference to Warnbold's conclusions from similar investigations (E. S. R., 18, p. 16).

The conclusion is reached that in soil studies involving the nitrogen balance a large series of determinations is indispensable and it is preferable to have parallel series of determinations by two skilled analysts. Soil samples may be dried without loss of nitrogen when slightly acidified. The conclusion of Warnbold that sterilized soil fixes free nitrogen in considerable amounts was not confirmed.

In many soils the weighing of samples for air-dried material is not considered accurate.

On the nitrogen compounds in cultivated soils, T. PFEIFFER (*Fühling's Landw. Ztg.*, 55 (1906), No. 22, pp. 749-752).—This is an author's abstract of the above article.

Evaporation and drainage from fallow, loam, and sandy soils, C. VON SEELHORST (*Jour. Landw.*, 54 (1906), No. 4, pp. 313-315).—Observations on drainage and evaporation from loam and sandy soils in large vegetation tanks from October, 1904, to March, 1906, are reported. These show, in general, that the evaporation was largest and the drainage smallest from the loam soil during the fall and winter. With sandy soils this was true in summer.

The drainage was, as a rule, larger and the evaporation smaller from the sandy soil than from the loam. The greater evaporation from the loam soil is attributed to lower percolation and greater capillary capacity in this soil. Greater evaporation from the sandy soil was observed only during a period of high temperature and heavy rainfall in summer.

Nitro-culture and inoculation, O. M. BALL (*Texas Sta. Bul.* 83, pp. 15).—Two series of pot cultures carried out during the winter and spring of 1904-5 and the fall of 1905 are reported.

"In the first series the object was to determine whether nodules will appear on the roots of alfalfa when this plant is grown in soils where none had ever before been cultivated, but which produced a fine growth of bur clover (*Medicago denticulata*), and, further, whether the nodules already present on the roots of bur clover could be carried over to alfalfa when grown in soil that had previously been sterilized; in short, whether artificial inoculation of alfalfa with the germs from bur clover is feasible. In the second series the question was to determine the value, if any, of the so-called nitro-culture and other like 'cultures.'"

A variety of soils was used in the first series, and the method of procedure was much the same in the two series of experiments. The first series showed in brief that alfalfa will become infected with the tubercle-forming organism (*a*) when grown in soil which has produced a crop of bur clover, (*b*) after being watered with a solution of such soil, and (*c*) by means of an infusion of the root nodules of bur clover. The results of the second series of experiments indicate that inoculation with nitro-culture is of doubtful value "since only a small proportion of the plants treated developed tubercles, and these were in no observable degree benefited by their presence. In no case of artificial inoculation were the

number and vigor of the tubercles so great as in that occurring by natural means."

The nutrition of cultivated plants, G. SMETS (*La Nutrition des Plantes Cultivées. Macseyck: Vanderdouck-Robyus, 1905, 2. ed., pp. 272, figs. 2*).—This book summarizes briefly but clearly information drawn largely from the author's own work regarding the general laws and principles of plant nutrition and elaboration of plant food, the behavior of fertilizing substances in the soil, various kinds and classes of manures and fertilizers, fertilizer requirements of Belgian soils, and the use of fertilizers on different kinds and classes of crops and soils. Numerous references to accounts of investigations upon which the book is based are given.

The management of stable manure in the heap, A. SRUTZER (*Fühling's Landw. Ztg., 55 (1906), No. 13, pp. 436-442, figs. 4*).—A general discussion of this subject.

On storage of liquid manure (*Ber. K. Vet. og Landbohøjskoles Lab. Land-økonom. Forsøg [Copenhagen], 69 (1906), pp. 140-142*).—Experiments on conservation of liquid manure were conducted in connection with the investigation of the protein minimum for dairy cows, reported elsewhere (E. S. R., 18, p. 668). Sulphuric acid or peat litter in different quantities was added to definite amounts of urine and the mixture left standing in glazed crocks or in bottles for about six months. The nitrogen content was determined at the beginning and the end of the trials. The losses of nitrogen obtained were as follows: 1,000 gm. urine alone, 79.5 per cent; urine and peat litter, 5:1, 62.4 per cent; 1:1, 17.7 per cent; 1:2, no loss; 1:3, 1.8 per cent; urine in a stoppered bottle connected with a bent glass tube, the other end of which was placed under sulphuric acid, no loss; urine left standing under similar conditions as in last experiment, except that the tube was not sealed by sulphuric acid, but was left open, no loss.

The practical deduction drawn from the experiments is that a liquid-manure cistern should be made water-tight and closed with a tightly fitting cover which will prevent escape of ammonia in the air above the liquid.—F. W. WOLL.

Value of moss litter (*Jour. Bd. Agr. [London], 13 (1906), No. 6, pp. 360, 361*).—Tests of the absorbent capacity and value as litter for stables of this material are briefly reported, the high absorbent capacity of the material for both nitrogen and water being clearly shown. Manure with which this litter was used was apparently quicker in action than that with which straw was used.

Water as a plant food, A. BACKHAUS (*Verhandl. Gesell. Dent. Naturf. u. Aerzte, 1905, II. 1. Abt., pp. 123-127; abs. in Chem. Centbl., 1906, II, No. 18, p. 1453*).—See also E. S. R., 17, p. 1055.

Artificial manures in Japan (*Abs. in Jour. Soc. Chem. Indus., 25 (1906), No. 19, p. 942*).—Data are reported showing that the demand for fertilizers in Japan is very active, prices rising, and production increasing. The imports consist mainly of ammonium sulphate, oil cake, and phosphates. The greater part of the sardines caught in Japanese waters, valued at about \$3,650,000, are ultimately used as manure. (See also E. S. R., 17, p. 1140.)

Report on commercial fertilizers, 1906, E. H. JENKINS, A. L. WINTON, ET AL. (*Connecticut State Sta. Rpt. 1906, pt. 1, pp. 106*).—Analyses of 559 samples of commercial fertilizers and manurial waste products examined during the year are reported and discussed with reference to variation in composition and commercial value. The fertilizers examined are classified as follows: Containing nitrogen as the chief valuable ingredient, 118 samples; containing phosphoric acid as the chief valuable ingredient, 11 samples; containing potash as the chief valuable ingredient, 39 samples; containing nitrogen and phosphoric acid,

55 samples; mixed fertilizers, 278 samples; and miscellaneous fertilizers and manures, 58 samples.

Fertilizer inspection, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 133*, pp. 177-208).—"This bulletin contains the analyses of samples collected by the station of the brands of fertilizers licensed in 1906."

Commercial fertilizers, H. J. WHEELER ET AL. (*Rhode Island Sta. Bul. 115*, pp. 15).—"In this bulletin will be found analyses of such potato and vegetable fertilizers as have been found on sale in Rhode Island during the spring of 1906, also analyses of similar samples of bone and tankage."

Analyses of commercial fertilizers, B. L. HARTWELL ET AL. (*Rhode Island Sta. Bul. 117*, pp. 37-52).—"This is a second report on inspection of fertilizers in 1906, and includes analyses and valuations of 85 samples of fertilizing materials."

Commercial fertilizers and chemicals, T. G. HUDSON, J. M. McCANDLESS, ET AL. (*Bul. Ga. Dept. Agr., 1906, No. 43*, pp. 136).—"This is a report on inspection of fertilizers on sale in Georgia during the season of 1905-6, including the text of the fertilizer and pure food laws of the State, regulations regarding conduct of inspection, notes on valuation, and tabulated analyses and valuations."

A test of nine phosphates with different plants, H. J. WHEELER and G. E. ADAMS (*Rhode Island Sta. Bul. 114*, pp. 115-137).—"The experiments reported in this bulletin were begun in 1894 and have been partly reported upon in a previous bulletin (E. S. R., 11, p. 642)."

The experiments were made on limed and unlimed series of plats ($\frac{2}{15}$ acre), which from 1894 up to the date of the experiments here reported had at different times (1894, 1895, 1899) received applications of dissolved boneblack, dissolved bone, acid phosphate, double superphosphate, floats, fine-ground bone, basic slag, and raw and roasted redondite, aggregating in the majority of cases 98.5 lbs. of phosphoric acid per plat, or at the rate of 738.6 lbs. per acre. The bulletin reports experiments on these plats with corn in 1900 and with a large variety of other crops, including potatoes, barnyard grass (*Panicum crus-galli*), oats, millet, soy beans, Adzuki beans, peas, squashes, turnips, cabbage, crimson clover, and beets, in 1901. In every case the phosphates were used in connection with a liberal basal fertilizer consisting of nitrate of soda and potash salts.

In the case of corn all the phosphates were as a rule more effective on limed than on unlimed soil. Raw redondite was much less effective than roasted on limed soils, while the two were of about equal efficiency on unlimed soil. Floats gave good results in these experiments, although the material was very inefficient on corn the first year it was applied. The results with double superphosphate showed very low efficiency on unlimed soils, and dissolved boneblack gave "exceptionally poor results," which it is suggested were possibly due to the effect of drought, which was especially severe on the plats on which this material was used.

"With the pea, oat, summer squash, crimson clover, Japanese millet (on the unlimed land), golden millet, white-podded Adzuki bean, soy bean, and potato (on the unlimed land) floats gave very good results; but with the flat turnip, table beet, and cabbage they were relatively very inefficient, notwithstanding that much more phosphoric acid had been applied in the floats than in any other of the phosphates."

"In the case of the pea, oat, summer squash, crimson clover, Japanese millet, golden millet, cabbage, soy bean, and potato the yields were less on the limed soil with than without the raw redondite. With but one or two exceptions the yields were raised somewhat by its use on the unlimed land."

Liming exerted a marked influence in increasing the efficiency of roasted

redondite, especially in case of summer squash, crimson clover, Japanese millet, Adzuki beans, and several other plants.

In case of crimson clover and Adzuki beans the raw redondite seemed to be more beneficial than the roasted. The roasted redondite was of little value in case of beets and cabbage on limed land. "Double superphosphate particularly, and in some cases dissolved boneblack and acid phosphate, proved relatively inefficient upon the unlimed land, and a few instances of the same kind were observable even where the land had been limed, particularly in the case of those plants which are liable to injury upon soil which strongly and intensely reddens blue litmus paper and which is at the same time practically devoid of carbonate of lime.

"Liming, instead of proving injurious in connection with the soluble phosphates, as is so often alleged, proved decidedly helpful in the majority of cases, and even in many instances with plants which are not particularly in need of liming. The results seem to indicate that in a soil deficient in or devoid of carbonate of lime and well supplied with the oxids of iron and aluminum, liming may extend the period of efficiency of the soluble phosphates possibly by combining with much of the phosphoric acid at once, and thus holding it in more assimilable combinations than if it were possible for it all to unite immediately with the iron and aluminum oxids. . . .

"Double superphosphate seemed to be the least adapted to acid soil of any of the soluble phosphates, namely, the dissolved bone, dissolved boneblack, and acid phosphate.

"Finely ground unacidulated steamed bone failed to fully meet the needs of some of the crops in the earlier years, but this condition soon ceased and it has given excellent results for several years, and has shown a much greater efficiency than the floats, even though a much larger quantity of phosphoric acid had already been applied in the latter than in the bone.

"Basic slag meal has proved throughout to be a highly efficient phosphatic manure. Its relative efficiency has been particularly high where those plants have been grown which are helped by liming. This is doubtless due in part to the fact that it contains far more lime than bone meal or floats. The use of fine-ground bone, basic slag meal, and floats has tended continually to make the unlimed land more favorable to clover."

In general there was little or no evidence that the nitrogen of the bone and dissolved bone was of particular advantage in increasing the yields obtained with these materials.

It is pointed out that the results in general show that care should be taken to distinguish between available and soluble phosphoric acid in the selection of fertilizers. It is also thought that the results show that the Rhode Island gardener and general farmer will do well to exercise caution in the use of floats, confining this use to especially favorable conditions, such as moist soils rich in decaying vegetable matter, and in case of such crops as certain legumes, Indian corn, millet, and possibly wheat and oats, which seem better adapted to utilizing the material to advantage than certain vegetables.

Comparative fertilizer tests of Thomas slag and agricultural phosphate, CLAUSEN (*Fühling's Ztg.*, 55 (1906), No. 19, pp. 640-670, figs. 9; *Mitt. Deut. Landw. Gesell.*, 21 (1906), No. 47, pp. 448, 449; *Deut. Landw. Presse*, 33 (1906), Nos. 92, pp. 727, 728; 100, pp. 784, 785).—Comparative pot tests during 1903 to 1905 with rye grass, oats, and celery on different kinds of moor soil are reported, the two phosphates being used alone and in combination with kainit, ammonium sulphate, and nitrate of soda, and also compared with superphosphate and bone meal.

The efficiency of the phosphates apparently depends to a large extent upon their action in association with other fertilizing materials, particularly those containing nitrogen. Apparently both Thomas slag and agricultural phosphate (fine-ground mineral phosphate) may cause a considerable loss of nitrogen during dry hot weather when applied in connection with nitrogenous fertilizers, especially ammonium sulphate, but the loss is greater in case of Thomas slag than in case of the agricultural phosphate. For this reason the net result with Thomas slag in such cases was not greatly superior to that obtained with agricultural phosphate, although a given amount of phosphoric acid in form of the slag is as a rule much more effective than the same amount in form of agricultural phosphate. The use of potash salts appeared to reduce the loss of nitrogen resulting from the action of the phosphates. The loss of nitrogen was greatest when the nitrogenous materials were applied as top-dressing.

In a later article the author refers to the work of Priamishnikov on the influence of ammonium sulphate on the solubility of phosphates as furnishing a possible explanation of the high availability of agricultural phosphate reported by certain investigators, especially Bachmann (*Z. S. R.*, 17, p. 17). He also emphasizes his previous conclusion that in certain cases Thomas slag exerts a decided influence in rendering nitrogen of the soil less available.

Comparative tests of Thomas slag and agricultural phosphate as fertilizers, BACHMANN (*Deut. Landw. Presse*, 33 (1906), No. 89, p. 707).—The author criticises some of the conclusions of Clausen in the article above referred to.

Comparative fertilizer tests of Thomas slag and agricultural phosphate, BÖTTCHER and BACHMANN (*Deut. Landw. Presse*, 33 (1906), No. 98, pp. 768, 769).—This is a further discussion of this subject based upon the experiments referred to in the articles noted above.

Phosphate of lime in Algeria (*Abs. in Jour. Soc. Chem. Indus.*, 25 (1906), No. 19, p. 942).—The large and easily accessible deposits in the Province of Constantine, namely, those of Tébessa, Sétif, Guelma, and Aïn-Beïda, are discussed. Two classes of phosphate are now handled, (1) that containing 63 to 70 per cent of calcium phosphate, and (2) that containing 58 to 63 per cent. The cost at the quay at Bona is at present from \$2.64 to \$2.88, the price being higher than it should be on account of unsatisfactory transportation facilities.

Crude ammonia, M. DE MOLNARI and O. LICOT (*Bul. Agr. [Brussels]*, 22 (1906), No. 5, pp. 571-577, figs. 2).—Pot tests with oats of this material (concentrated gas house liquor) in comparison with nitrate of soda are reported. The growth was normal with both materials, but the nitrate was the more effective fertilizer. The crude ammonia used in these experiments contained 2.28 per cent of ammoniacal nitrogen, 1.96 per cent of organic nitrogen soluble in water, and 1.78 per cent of organic nitrogen insoluble in water. Comparative tests of the complete material with that containing only the organic nitrogen soluble in water or that insoluble in water showed that the organic nitrogen soluble in water was less effective than the complete material and that the organic nitrogen insoluble in water had no effect whatever.

The cause of the lower efficiency of ammoniacal nitrogen in comparison with nitric nitrogen (*Deut. Landw. Presse*, 33 (1906), No. 78, p. 624).—A brief review is here given of a report by Wagner on this subject in another journal, summarizing the results of 4 years' field and pot experiments.

The average of a large number of such experiments shows that if the efficiency of nitrogen in nitrate of soda on grains, beets, and potatoes, be taken as 100, the comparative efficiency of ammoniacal nitrogen is for barley 72, for oats 91, for winter wheat 98, for winter rye 76, for potatoes 88, for fodder beets 53, and for sugar beets 73. Against the more lasting effect of the ammoni-

aeal nitrogen must be set the loss of nitrogen by volatilization of ammonia or ammonium compounds.

Laboratory and pot experiments show that when ammonium salts are applied to soils containing considerable amounts of calcium carbonate there is a considerable loss of nitrogen in the form of ammonium carbonate, especially if the ammonium salts are applied on the surface of a moist soil and allowed to lie some time before being cultivated in. These facts explain why ammonium salts give better results as a rule upon soils poor in lime than on those containing an abundance of this material, and why they are more efficient when thoroughly mixed with the soil than when applied as a top-dressing. It is not believed that the conversion of a part of the nitrogen of ammonium salts into less readily available forms by the action of soil bacteria plays any appreciable part in reducing the efficiency of this material as a fertilizer.

Field experiments on the fertilizing action of sulphate of ammonia as compared with nitrate of soda, KRETSCHMER ET AL. (*Arb. Deut. Landw. Gesell.*, 1906, No. 121, pp. XXI+234, map 1; *abs. in Mitt. Deut. Landw. Gesell.*, 21 (1906), No. 42, pp. 103-105).—Cooperative experiments by the Wagner method at the experiment stations of Bonn, Bernberg, Halle, and Köslin in continuation of those by Wagner already noted (*E. S. R.*, 15, p. 234) are reported.

The results, as in other experiments, vary with the character of the soil, weather, and crop, although in general nitrate of soda gave better results than ammonium sulphate, thus confirming Wagner's conclusions. In many cases, however, the ammonium sulphate was more effective than nitrate of soda. The nitrate is apparently better suited to acid soils than the sulphate. On the other hand, ammonium sulphate is more efficient than the nitrate on leachy soils in wet seasons.

The results show quite clearly that ammonium sulphate should not be used as a top-dressing on soils rich in lime. A map is given which shows the locations of sources of supply of fertilizing materials of various kinds.

Is nitrogen lost from the soil in fertilizing with nitrate of soda? J. STOKLASA (*Centbl. Bakt. [etc.]*, 2, *Abt.*, 17 (1906), No. 1-2, pp. 27-33; *abs. in Chem. Ztg.*, 30 (1906), No. 90, *Repert. No.* 43, p. 386; *Chem. Centbl.*, 1906, 11, No. 25, p. 1778).—Recent investigations regarding denitrification are briefly reviewed and culture experiments in which 50 gm. samples of unmanured soil, of soil fertilized with barnyard manure, and of soil fertilized with nitrate of soda, were mixed with 500 cc. of Giltay solution, and the changes which the nitrogen underwent were observed, are reported.

The results confirm in general those of previous investigations by the author and lead to the conclusion that in the reduction of nitric acid to elementary nitrogen, nitrous acid is always an intermediary product. The reduction of the nitric acid to nitrous acid is brought about by the action of nascent hydrogen, which is set free along with carbon dioxide by the cleavage action of enzymes on carbohydrates or organic acids.

The Bavarian beet soils used in these investigations were so deficient in a readily assimilable carbon supply for the respiration processes of the denitrification organisms that nitric acid was not reduced to elementary nitrogen in these soils to a sufficient extent to be detected by ordinary analytical processes. With free access of air such as accompanies ordinary thorough cultivation of soils or in soils of high air capacity loss of elementary nitrogen through denitrification does not occur, although nitrites are always formed from nitrates.

Can calcareous fertilizers be held responsible for a deficiency of nitrogen in soils? CLAUSEN (*Illus. Landw. Ztg.*, 26 (1906), No. 78, pp. 674, 675, *figs.* 3).—Pot experiments with clover and oats on sandy soil are reported, which

indicate that applications of lime resulted in case of such soils in a marked "nitrogen hunger," especially during dry hot weather and with nonleguminous crops. Under such conditions calcareous manures should always be accompanied by liberal applications of nitrogenous manures.

Nitrate of soda, A. PLAGEMANN (*Die Düngstoff-Industrien der Welt: Der Chilesalpeter*. Berlin: Der Saat-, Dünger- und Futtermarkt, [1906], pp. 80, pls. 2, figs. 20).—This is one volume of a large treatise on the fertilizer industry of the world and is a very full account of the character and exploitation of the Chilean nitrate deposits.

Lime niter for potatoes, L. GRANDEAU (*Jour. Agr. Prat., n. ser., 12 (1906), No. 42, pp. 485, 486*).—Comparisons of nitrate and nitrite of lime (the Notodden product) and nitrate of soda in field experiments at Parc des Princes in 1906 are reported, which show that for this crop there was practically no difference in the efficiency of the different fertilizers.

Dry fertilizer from by-products or residues from sugar works, E. LALLEMANT (*French Patent No. 365,448, Apr. 20, 1906; abs. in Jour. Soc. Chem. Indus., 25 (1906), No. 20, p. 997*).—In the method proposed the damp materials are made into briquettes, which are air-dried, or dried at a moderate temperature in a kiln, or the material is mixed with quicklime or roasted gypsum in lumps.

On the use of sulphocyanids as fertilizers, R. PEROTTI (*Staz. Sper. Agr. Ital., 39 (1906), No. 3, pp. 193-212, fig. 1; abs. in Chem. Central., 1906, II, No. 16, p. 1282*).—The material used in the pot experiments here reported is manufactured in Belgium from gas liquor. The sample examined by the author contained 5.06 per cent of total nitrogen, 1.66 per cent of ammoniacal nitrogen, 0.8 per cent of phosphoric acid, 2.28 per cent of potash, 1.78 per cent of lime, 23.88 per cent of sulphur, and 4.5 per cent of ammonium sulphocyanid.

The results obtained with a number of crops, including wheat, oats, corn, flax, etc., show that unless the sulphocyanid is present in the soil in highly concentrated solution there is little danger of injury to vegetation. The material undergoes a rapid and complete transformation in the soil without loss of nitrogen. Considered as a source of nitrogen it was in these experiments somewhat more economical than ammonium sulphate. It is proposed to test the results of the pot experiments by experiments in the field.

AGRICULTURAL BOTANY.

Botanical studies applied to agricultural plants, G. FROX (*Traité Élémentaire de Manipulations de Botanique Appliqué à l'Étude de Plantes Agricoles*. Paris: C. Amat, 1907, pp. VII+228, figs. 137).—This work treats mainly of the gross and minute anatomy of agricultural plants. It is not intended as a substitute for some of the more comprehensive botanical treatises, but is offered as a guide to the study of a number of types illustrative of the large number of agriculturally important plants.

After a rapid review on the uses of the microscope, its technique, methods of preparation, etc., studies are given of a number of plant products. The author then takes up the following plants which are representative of types: Onion, asparagus, wheat, grape, bean, pea, sugar beet, hemp, flax, mustard, cabbage, potato, tobacco, gourd, dodder, broom rape, *Melampyrum*, Jerusalem artichoke, carrot, parsnip, etc. Following these, studies are given on the structure of various timbers used in construction, including oak, walnut, beech, alder, pine, spruce, etc.

A brief bibliography of some of the more important literature is given at the end of each chapter.

Hybridization of wild plants, D. T. MACDOUGAL (*Bot. Gaz.*, 43 (1907), No. 1, pp. 45-58, figs. 4).—The author discusses the hybrid origin of a number of so-called natural hybrids that exist wild, and in some instances he thinks the evidence favors such hybridity. The various conditions under which hybrids can be formed are described, and a list is given of natural hybrids that have been reported as occurring in the indigenous flora of North America.

The action of ozone on germination, H. MICHEELS and P. DE HEEN (*Acad. Roy. Belg., Bul. Cl. Sci.*, 1906, No. 6, pp. 364-367, pls. 2).—The general interest in the physiological action of ozone, due not only to the radio-activity and other properties of the gas, but also on account of its frequent production in the air, led the authors to study its effect on the germination of wheat. A specially devised apparatus was constructed to cut off the effects of static electricity, and after a preliminary soaking for 24 hours in tap water the seeds were placed to germinate, checks being maintained without ozone. In every instance the ozone had an injurious effect as shown not only in a decreased number of germinations, but also in a marked diminution in the weight and size of the seedlings.

The stimulating action of manganese on germination, H. MICHEELS and P. DE HEEN (*Acad. Roy. Belg., Bul. Cl. Sci.*, 1906, No. 5, pp. 288, 289).—Various investigators having shown the stimulating effect of manganese sulphate on rice (E. S. R., 16, pp. 42, 43) and on oats (E. S. R., 17, p. 954), the authors carried on experiments to determine the effect of a colloidal solution of manganese on the germination of wheat, comparisons being made with a colloidal solution of tin.

In other experiments of the authors ^a a colloidal solution of tin was found to stimulate the germination of peas and wheat. Not only was a greater percentage of germination obtained, but there was a decided increase in the weight of the seedlings and the length of the root development. In the experiments with the colloidal solution of manganese even more marked stimulating effects were observed. These colloidal solutions are believed to act upon the reserve material of the seed, having a sort of diastatic rôle.

The effect of different solar radiations on the nitrogen content of wheat, J. DUMONT (*Compt. Rend. Acad. Sci. [Paris]*, 143 (1906), No. 26, pp. 1179-1181).—In continuation of previous experiments (E. S. R., 17, p. 1145), the author has studied the effect of different colored screens on the nitrogenous material in wheat.

In the experiments reported equal areas of wheat in full flower were covered with frames containing different colored glass, and the effect of the different radiations on the total yield of straw, chaff, and grain, as well as the difference in the nitrogen content, was noted. Comparisons were made with equal areas of wheat grown in the open air and under frames containing clear glass.

The total yields per square meter of straw, chaff, and grain for the different lots were as follows: Open air 666 gm., under clear glass 670 gm., black, or where all the visible spectra were cut off, 846 gm., green 856 gm., red 912 gm., and blue 952 gm.

The nitrogen, albuminoids, and gluten were determined. There was found to be a progressive increase in the amount of nitrogen through the clear, red, and green glass to the blue, after which there was a falling off toward the other end of the spectrum. An examination of the figures presented shows that there is a decided influence on the nitrogen content of the plant on the part of the more refrangible rays of the spectrum. By reducing the amount of nitrogenous mate-

^a Acad. Roy. Belg., Bul. Cl. Sci., 1905, No. 7, pp. 310-318,

rial to percentages there is shown to be at least 30 per cent increase in the total nitrogen in the plants grown under the blue glass.

The author claims that these experiments, as well as those previously reported, show that the radiations at the right of the spectrum assist very materially in the translocation of nitrogenous materials, particularly the gluten in the wheat grain during the time of its ripening. They also favor the formation of albuminoids, and it is claimed that their physiological action is no less important than that of those at the other extremity.

Toxic limits and stimulation effects of some salts and poisons on wheat, G. H. JENSEN (*Bot. Gaz.*, 33 (1907), No. 1, pp. 11-44, figs. 34).—The present work was undertaken for the purpose of ascertaining the toxic limit for wheat plants in both solutions and soil cultures. The wheat seeds were germinated in sphagnum and in quartz and transplanted to water cultures or to paraffined wire baskets containing ground quartz, after which they were supplied with culture solutions containing different strengths of copper sulphate, lead nitrate, silver nitrate, zinc sulphate, iron nitrate, iron chlorid, nickel nitrate, phenol, and alcohol.

The responses to the toxic salts are said to be of two kinds, acceleration and a retardation of growth which progresses as the concentration increases until the death point is reached.

The author compared the effect of the different substances tested on the total transpiration from each pot or culture, the average length of the sprout, the green weight and the dry weight of the plants.

The different series of investigations are reported at length, and in conclusion the author points out that while considerable work has been done on toxicity, none has shown the definite effects of a poison in pure soil. Such experiments as have been made with garden loam are unreliable because of the multiplicity of inorganic and organic substances with which the introduced poison may react. The author's investigations have shown that the introduction of pure quartz flour into a toxic solution, in such proportion as to form an ordinary moist soil, reduces the toxicity of the solution in a marked degree. Whether this is due to absorption, to a reduced freedom of movement of the soil particles, or to some chemical changes is yet to be determined.

Of the poisons tested all gave stimulating results in quartz, and all but zinc and copper sulphates in the solution cultures. It is thought probable that in proper concentration these 2 might also be found stimulating.

The more dilute the fatal dose in solution, the more the toxic effect is reduced by the introduction of quartz. Hence the range of concentrations, both fatal and accelerating, is much greater in solution than in soil cultures.

The report concludes with a bibliography of literature relating to the subject.

Some investigations on the injury to plants by sewage, P. EHRENBERG (*Ztschr. Pflanzenkrankh.*, 16 (1906), No. 4, pp. 193-202).—A study was made to determine the effect on plant life of sewage from a sewage-disposal farm.

It was found that the paper pulp, fat, and various salts carried by the sewage had an injurious effect on all crops experimented with, the paper pulp and fat being mechanically injurious, while the salts were chemically noxious. In the case of cereals the plats receiving the sewage were later in ripening and yielded less grain in proportion to straw than where no sewage was applied. In a number of instances there seemed to be a greater tendency to plant diseases on the treated plats.

The influence of concentration of nutrient solutions on the development of

some algæ, A. ARTARI (*Jahrb. Wiss. Bot. [Pringsheim]*, 43 (1906), No. 2, pp. 177-214; *abs. in Bot. Centbl.*, 102 (1906), No. 23, p. 595).—Experiments were carried on with a number of species of green algae in which the influence of different concentrations of nutrients was studied.

It was found that ammonium nitrate, which served as a source of nitrogen for the algae, was without appreciable effect in solutions of 0.05 to 0.5 per cent. Higher concentrations retarded growth, until at 5 per cent all growth ceased. From the action of various salt solutions they were believed to have other effects than those due to their osmotic activity. The nutritive value of the different solutions of nitrogen varied somewhat, depending upon whether or not glucose was present in the solution. The stimulating effect of the glucose was apparent in strengths as low as 0.005 per cent, and it increased to an optimum for the different species of algae between 0.5 and 2 per cent. The limit of concentration of the disaccharids was found to be almost double that of the monosaccharids.

The retarding effect of sodium chlorid was very evident even in the weakest solution, and with an increase in strength of the solution the injurious effect was quickly shown. Magnesium sulphate had only a slight retarding influence.

Tannin cells of persimmons, B. J. HOWARD (*Bul. Torrey Bot. Club*, 33 (1906), No. 11, pp. 567-576, figs. 8).—In a previous publication an account is given of the changes which take place in the tannin cells of persimmons during ripening (*E. S. R.*, 17, p. 613), and in the present paper the subject is discussed at considerable length.

The author has found that the tannin cells in the different species of persimmon examined differ materially in appearance and that the changes taking place during the ripening process may be divided into three stages.

In the green stage the tannin does not appear to be strongly localized, for though it appears most abundantly in the loose parenchyma tissue where the tannin cells are located, yet it is not limited to these cells nor even to the region where the cells are most abundant.

In the second stage of ripening radical changes occur in the physical and possibly in the chemical constitution of the tannin. The tannin at this stage is being or has been collected into the tannin cells, and the contents of these cells become highly refractive.

In the last stage the tannin masses have become highly refractive and the addition of water causes little, if any, swelling. The contents of the cells are friable, and pressure upon the cover slip results in the fracturing of the tannin masses into irregular fragments.

While the disappearance of the astringency and the development of mushiness of the fruit are commonly associated, the author found that these features do not run parallel, as it frequently occurs that mushiness develops before the astringency is gone, while in other cases just the reverse is true. This is the case particularly in specimens of Japanese persimmons cured by the saki process.

A study of beans yielding hydrocyanic acid, L. GUIGNARD (*Rev. Vit.*, 26 (1906), Nos. 655, pp. 5-9, pl. 1; 656, pp. 33-37; 658, pp. 89-95; 667, pp. 341-350, figs. 9; 674, pp. 543-547; 675, pp. 573-576; 677, pp. 626-631; 678, pp. 663-667; 679, pp. 689-694; 680, pp. 715-721).—An historical, botanical, and chemical study is given of *Phaseolus lunatus*, a number of the varieties of which have poisonous properties due to hydrocyanic acid. A number of forms that have been described as distinct species are by the author believed to be varieties or cultural forms of *P. lunatus*. Those principally studied were the white and colored Java beans, Burma or white Indian beans, Sleva beans, Cape beans, which are extensively cultivated in Madagascar, and Lima beans. These dif-

ferent varieties are widely cultivated and extensively used as food, although a number of fatalities have been attributed to their use. Descriptions of the different varieties and detailed reports of the chemical studies are given.

Practically all varieties of *P. lunatus*, whether wild or cultivated, were found to contain the principle which when acted upon by an enzyme yields hydrocyanic acid. The proportion of hydrocyanic acid varied from almost inappreciable amounts in some of the more improved forms, like the Lima bean, to as much as 60 to 320 mg. per 100 gm. dry weight in certain varieties of Java beans. It was found impossible by cooking to remove all the cyanogenetic compound in Java beans. Prolonged boiling extracts the greater part, but it is merely withdrawn and not destroyed, and if the water is absorbed it presents the same danger as the beans themselves, since either in the alimentary tract or in the blood there are sufficient ferments to act upon the dissolved glucosid, resulting in the liberation of hydrocyanic acid.

Incidental to the investigation the author discovered a new method for detecting the presence of hydrocyanic acid in plants. It is based upon the action of hydrocyanic acid in changing to a red color a mixture of picric acid and an alkali through the formation of isopurpuric acid. Strips of blotting paper are soaked in an aqueous solution of picric acid, dried, impregnated with a solution of carbonate of soda, and again dried. A strip of this paper suspended in a test tube containing 1 or 2 cc. of liquid containing hydrocyanic acid will after a time take on an orange red color, afterwards changing to red, the rapidity of coloration depending upon the temperature and amount of acid in the solution. A solution containing 0.005 mg. of hydrocyanic acid will change the paper to orange red in 12 hours, and 0.002 mg. will be indicated within 24 hours.

A second Ohio weed manual, A. D. SELBY (*Ohio Sta. Bul.* 175, pp. 291-384, figs. 73).—This is a revised and enlarged edition of Bulletin 83 of the station (E. S. R., 9, p. 1054).

After an introductory statement regarding the nature of weeds, methods of introduction and spread, vitality of weed seeds, etc., the author gives an illustrated descriptive list of 385 species of weeds that have been observed to occur in Ohio. The more obvious characters of each weed are described and illustrations presented of those which are most injurious or which have been but recently introduced. Wherever possible the seed characters of the plants are presented. The descriptive list is arranged according to the plant families, the common and scientific names being given.

The author calls attention to the occurrence of foreign seeds found in various samples of commercial seed, listing the species of weed seeds that have been observed in red clover, alfalfa, alsike clover, timothy, and oats.

FIELD CROPS.

A successful hog and seed-corn farm, W. J. SPILLMAN (*U. S. Dept. Agr., Farmers' Bul.* 272, pp. 16, figs. 5).—This bulletin contains a description of the system of management on a successful hog and seed-corn farm in Illinois. The main points discussed are the general management of the farm, the construction of shelters for hogs, the culture of soy beans and corn, the feeding value of corn, clover, and soy beans, the rotations followed on the farm, and the financial results secured.

Forage crop practices in western Oregon and western Washington, B. HUNTER (*U. S. Dept. Agr., Farmers' Bul.* 271, pp. 39, figs. 4).—This bulletin is identical with Bur. Plant Indus. Bul. 91 (E. S. R., 18, p. 229).

Annual report of the Burdwan Agricultural Experiment Station for

1905-6, F. SMITH (*Ann. Rpt. Burdwan Expt. Sta. [India], 1905-6, pp. 29+ XV*).—A brief description of the station and its work for the year is given.

The results with rice indicate that the use of cow manure and nitrate of soda, as well as green manuring with jute and dhaincha, is profitable. Transplanting seedlings to about 12 in. apart proved most satisfactory. The varieties of rice considered the best were Badshahbhog and Dadkhani from Bengal and Kamod from Bombay. Varieties of jute giving the best results are enumerated. Thinning out plants to 4 in. apart and sowing the third week of April in the Burdwan district is recommended. The use of cow manure considerably increased the yield of fiber.

Annual report of the **Cuttack Agricultural Experiment Station for the year 1905-6**, F. SMITH (*Ann. Rpt. Cuttack Expt. Sta. [India], 1905-6, pp. 12*).—A brief description of the station is given and the results of experimental work for the season are reported.

Of the different varieties of aman paddy tested Benaphuli ranked first in productiveness, with a yield of 2,000 lbs. of grain and 3,700 lbs. of straw per acre. Transplanting one seedling per hole proved most successful. The use of 60 lbs. of seed sown broadcast gave as good returns as the use of 50, 70, or 80 lbs. Irrigation gave a favorable increase in yield, and transplanting proved better than broadcasting. Only two varieties of aus paddy were compared, and of these the variety obtained from the Central Provinces was the more productive. A yield of 1,600 lbs. of peanuts per acre is reported and notes are given on the conservation of manure and the distribution of seeds.

Annual report of the **Dumraon Agricultural Experiment Station for the year 1905-6**, F. SMITH (*Ann. Rpt. Dumraon Expt. Sta. [India], 1905-6, pp. 16, fig. 1*).—Brief notes on the station are given and the results of experiments on sugar cane, paddy, wheat, mustard, and rape are reported.

In fertilizer experiments with sugar cane the use of cow manure and castor cake gave the best yields. Of the varieties tried Khari sugar cane proved hardiest. Of the three systems of sugar cane culture, the local, the Bihar Planters' system, and the Poona system, the last mentioned gave the best results. This system consists in laying out the land into beds 10 ft. square, each bed being divided into four trenches and ridges. A water channel for irrigating purposes extends around the bed and connects with each trench.

In fertilizer experiments with aman paddy the best yields were secured from the use of 2,560 lbs. of cow manure per acre. The results from fertilizer experiments with wheat show that the use of poudrette produced the highest yield of grain, but that the increase in yield was insufficient to pay for the fertilizer. Lying fallow in the bhadoi season gave the best economical returns. The red deshi variety of wheat proved to be the best general-purpose sort. Indian mustard of Raipur and of Jabbalpur are two varieties recommended for general planting.

The state farms, A. DESPEISSES (*Jour. Dept. Agr. West. Aust., 14 (1906), No. 5, pp. 333-342, pl. 1*).—Brief reports are given on the work at the three state farms at Chapman, Narrogin, and Hamel. At Chapman, in a variety test of wheat, Toby Luck ranked first, with a yield of 22 bu. per acre. This variety produced strong straw and plump grain. Brief notes are given on the different field crops grown at these stations.

Experimental stations [Report on field crops], E. CLIFTON (*New Zeal. Dept. Agr. Ann. Rpt., 14 (1906), pp. 186-245, pls. 23*).—Brief reports are given on work conducted at the Waerenga, Ruakura, Bickerstaffe, Selwyn, Motuhihi, Weraroa, and Momohaki stations.

Experiments in top-dressing grass land at Waerenga showed that a single application of 10 cwt. per acre produced the heaviest crop of grass, with the

largest proportion of leguminous plants. In growing potatoes a fertilizer application consisting of 6 cwt. of bone dust, 2 cwt. of kainit, 28 lbs. of sulphate of iron, and 4 cwt. of basic slag per acre was used. The results indicated that the kainit and sulphate of iron might have been omitted, and that the quantities used of bone dust, or blood and bone, and of basic slag probably formed the best application for this crop on the clay land in question. Seed potatoes imported from California produced the healthiest plants. Spraying with permanganate of potash solution did not keep the plants healthy, while those sprayed with Bordeaux mixture were satisfactory.

At the Ruakura station $\frac{1}{2}$ ton of basic slag per acre was not as effective on grass as 2 cwt. of dissolved bone. Fertilizer and culture tests with various field crops are reported without comment.

Algerian oats was in general the most rust-resistant variety of oats grown at Momohaki, and Abundance produced good crops. Marshall White Chaff wheat yielded 53 bu. per acre and Cape Barley 73.8 bu. Root crops responded quicker to superphosphate than to other forms of phosphoric acid. The use of 4 cwt. of superphosphate per acre produced a ton of increase in yield at a lower cost than any other application. Sutton Yellow Globe Mangold ranked first in production, with a yield of over 46 tons of roots per acre.

At the Weraroa station 4 imported varieties of oats, Abundance, Storm King, Scotch Potato, and Goldfinder, yielded 31.2, 36.2, 42.5, and 47.5 bu. per acre, respectively.

[Report on pasture and old land hay plats], D. A. GILCHRIST (*County Northumb., Ed. Com., Bul. 8, pp. 45-81, digms. 4*).—This bulletin contains a report on 3 different series of experiments in progress for a number of years.

The general results of all the trials show that for improving extensive areas of poor boulder clay pasture in Northumberland a dressing of 10 cwt. of basic slag per acre may be used with profit. Superphosphate and lime and phosphatic manures other than slag are useful for this purpose, but not so profitable. It is believed that the initial treatment may be advantageously followed by dressings of 5 cwt. of slag per acre about every 3 years, and the judicious feeding of cake to the grazing stock. For poor, old pasture on sandy soils slag, together with a potash manure, is recommended. The feeding of cake and the use of slag on poor pasture is considered as greatly aiding in the development of sweet herbage on the lowlands. Liming was found expensive and profitable only under special circumstances.

At Cockle Park applications of slag and barnyard manure were very effective in developing fine grass and clover on thin hay and pasture land. Where barnyard manure was applied potash and nitrogenous fertilizers were not profitable. In one instance in these tests the use of a complete commercial fertilizer in combination with barnyard manure gave very poor results.

The utilization of water by rye, barley, wheat, and potatoes, C. SEELHORST (*Jour. Landw., 54 (1906), No. 4, pp. 316-342*).—The results reported show that on clay soil wheat required 333 gm. of water for the production of 1 gm. of dry matter, rye 375 gm., and potatoes 66.3 gm. The amount of water used by rye during April and May was larger than the amount used by wheat, but after this period until harvest wheat used much more water than rye. From June 1 to June 21 the quantity of water used by rye increased slightly, while that used by wheat increased considerably. Both crops reached their maximum on June 21. The water utilization of the potato increased quite rapidly from the end of May to July 10, and from this date until August 1 it remained about the same. Beginning August 1, the quantity of water used decreased quite rapidly at first and then gradually until harvest.

On sandy soil the quantity of water used to produce 1 gm. of dry substance in the grains ranged from 446.5 gm. to 501.2 gm., while for potatoes the range was from 58.4 to 61.4 gm. It is pointed out that the quantity of water transpired by these plants stood in direct relation to the yield, and as the production of a crop is largely dependent upon the supply of available nitrogen in the soil, it is concluded that the requirements for nitrogenous fertilizers and water bear a relation to one another.

The effect of injury to the spike and the stem of grains, C. EEBHART and H. METZNER (*Fühling's Landw. Ztg.*, 55 (1906), No. 21, pp. 709-725).—A previous paper on this subject is reviewed and the results of later work are reported.

It was found in work with barley that injury to the spike caused a decrease of 14 per cent in the yield of grain, the breaking of the stem in the first or upper internode a reduction of 28 per cent, and a combination of the two injuries a loss in yield of 38.5 per cent. The quality of the grain was also affected, an injury to the spike, such as bending it out of shape, reducing the quality much more than the breaking of the upper internode, although the combined action of these two injuries reduced the quality to a greater extent than either one of them alone.

The stems of spring rye were injured June 12 and 20 and July 17. The reduction in yield caused by these injuries varied from 21 to 60 per cent. It was also noticed in these tests that the breaking of the first or upper internode reduced the yield much more than a similar injury to the second internode.

Observations were also made on the effect of hail on crops of barley, oats, rye, and wheat, and the reductions in yield due to injury to the spike and different parts of the stem were determined and are reported in a table.

Alfalfa seed testing, O. M. BALL (*Texas Sta. Bul.* 81, pp. 15, pl. 1, figs. 3).—Directions are given for testing the purity of alfalfa seed and the weed seeds frequently found in it, together with seeds sometimes used as its adulterants, such as bur clover and sweet clover, are described.

In 1905 the station tested 32 samples of alfalfa seed obtained from the wholesale seed houses of the State. In these samples 30 different weed seeds were found. The percentage of sand, trash, and broken seed varied from 0 to 29 per cent. Testing the vitality of the seed is also described. The results secured with the 32 samples showed their vitality or germinating power to vary from 49.5 to 96.5 per cent, the greater number having a vitality of over 80 per cent. The actual values of the seed samples in percentages varied from 39.6 to 96. The results in detail are given in a table.

First report on the fertilizer experiments with brewing barley in 1906, O. REITMAIR ET AL. (*Ztschr. Landw. Versuchs. Österr.*, 9 (1906), No. 2, pp. 975-1002).—Cooperative fertilizer experiments are reported in which barley was fertilized with superphosphate at the rate of 200 kg. per hectare for the purpose of determining how the use of phosphate alone might influence the protein content.

The average protein content of the barley on the unmanured plats was 9.38 per cent, and on the manured plats 9.44 per cent, calculating the water content of the barley at 14 per cent. Reductions in the protein content due to the use of superphosphate were in most cases very unimportant. The protein content of the barley grown on the plats was in most instances lower than that of the seed used, the average for the crop being 9.53 per cent, while that of the seed was 10.14 per cent. This is attributed to the favorable weather conditions during the season of 1906, and it is believed that the weather conditions constitute the greatest factor in determining the protein content of barley. No relation of the protein content in the crop to the protein content of the seed used was shown by the results secured.

In grouping the experiments according to the nitrogen content of the soil it was found that the relative frequency with which phosphoric acid produced an increase in yield declined with the nitrogen content of the soil. It is not believed, however, that the application of nitrogen on these soils is necessary to obtain the complete effectiveness of phosphatic fertilizers. The results further showed that a high nitrogen content of the soil is without influence on the protein content of the barley produced.

Corn selection, F. W. CARD (*Rhode Island Sta. Bul.* 116, pp. 19-35, figs. 9).—The purpose of the experiments here reported, which have been previously described (E. S. R., 17, p. 858), has been to determine the possibility of increasing the number of ears per plant by selection. The work was begun in 1898, but detailed records have been kept only since 1901. The variety under test was Potter Excelsior sweet corn. In 1901, 35 per cent of the plants bore more than one ear and in 1905, 90 per cent bore more than one ear, the highest number of ears from a single plant being 13. Selecting seed from the lower ear on the stalk was not as satisfactory as selection from the upper ear.

The selection, preservation, and preparation of seed corn, A. T. WIANCKO and G. I. CHRISTIE (*Indiana Sta. Circ.* 2, pp. 14, figs. 10).—The importance of this work is pointed out and detailed directions for carrying it into effect are given. In several of the poorer and better fields examined by the station the stand ranged from 65.6 to 89.6 per cent, and the number of ear-producing stalks from 49.2 to 84.8 per cent. In studying the effect of the irregularity of kernels on the regularity of drop in planters it was found that where middle or deep kernels only were used the planter dropped 3 kernels 92 times in 100 drops. Where shallow kernels were used, 3 kernels were dropped 95 times in 100 drops, as compared with 66 times where the whole ear was used and 75 times where deep and shallow kernels were mixed.

Hints on preparing for and holding local corn shows, A. T. WIANCKO and M. L. FISHER (*Indiana Sta. Circ.* 1, pp. 13, figs. 2).—Directions are given for the selection and preparation of exhibits of corn for show purposes. Notes are presented on the time and place of holding corn shows, the arrangement and disposition of the exhibits, the judging of the corn, and the premiums offered.

Breeding an early, rapid fruiting, and productive cotton, R. L. BENNETT (*Texas Sta. Bul.* 79, pp. 9, figs. 5).—This work has been previously noted (E. S. R., 16, p. 867). This bulletin contains a brief account of the breeding work during the 2 years these observations have been in progress.

The investigations have shown that early cottons have short joints, with the first fruit limbs near the ground, and that late cottons have long joints, with the first fruit limbs a considerable distance above the ground. For early fruiting in the plants selected the first fruit limbs should not be higher than the fifth joint above the seed leaf joint and the first primary or wood limbs not above the fifth joint and not exceeding four in number. For rapid fruiting the joints on the main stem, fruit limbs, and primary limbs must be short, preferably not over 2 or 3 in. The fruit limbs should grow in succession at each joint of the main stem and primary limbs and be continuous in growth for continuous fruiting, and for productiveness the bolls should be at least $1\frac{1}{2}$ in. in diameter, the percentage of lint to seed cotton not less than $33\frac{1}{2}$, and the growth rapid and vigorous. The rate of growth is considered very important, and it is pointed out that the larger the plant of the type the greater its inherent rate of growth, its earliness, rapidity of fruiting, and yield.

The improvement of the cottons of the Bombay Presidency, F. FLETCHER (*Agr. Jour. India*, 1 (1906), No. 4, pp. 351-389, maps 2).—Cotton culture in the Bombay Presidency is described and a review of some of the experimental

work with the crop, together with an outline of the improvement work is given. The 5 different cotton growing tracts of the Presidency are noted in detail.

Varieties of Egyptian cotton have been introduced and in the case of indigenous varieties at least one extremely promising hybrid has been secured, although sufficient seed has not yet been grown for distribution. In the variety tests the Broach variety did not give a larger yield of seed cotton per acre than Kumpta, but owing to better ginning results its value was at least 20 per cent greater. The percentage of fiber of both varieties was lower in years of small rainfall. In a comparison with the Egyptian Abassi, Sea Island gave a higher yield and the crop is estimated at about 30 per cent greater in value. Tree cottons gave promising, but as yet, indefinite results.

The application of heavy and medium dressings of barnyard manure largely reduced both the quality and the quantity of the crop. The fertilizer experiments and irrigation tests indicated that the quantity of manure applied must be regulated by the quantity of water the crop receives, and that in most parts of India water is by far the more important of the two. Commercial fertilizers have not shown themselves effective, but this is considered due to a shortage of rain.

Kumpta and American cotton planted in June and July gave much better yields than when planted in August and September.

Supply and distribution of cotton, D. C. ROPER (*Bur. of the Census [U. S.] Bul. 63, pp. 25*).—This bulletin constitutes a report on the supply and distribution of cotton for the year ending August 31, 1906. In addition to these statistics, the latest available data relative to the consumption of cotton and to the imports and exports of this staple and its manufactures in other important manufacturing countries are given.

The total supply was 13,055,260 running bales. Stocks held September 1, 1905, amounted to 1,934,548 bales. Cotton grown in 1905 returned as ginned after August 31, 1905, amounted to 10,248,947 bales and that grown in 1906 returned as ginned before September 1, 1906, to 407,551 bales. The shortage in ginners' returns of production for growth of 1905 as shown by distribution statistics was 336,739 bales, and the net imports for the year ending August 31, 1906, reached 127,475 bales. The distribution is summarized as follows: Exported, 6,673,041 bales; consumed, 4,909,479 bales; destroyed by fire, 25,760 bales; stocks held August 31, 1906, 1,356,980 bales.

Culture and utilization of cyperus, BUI-QUANG-CHIËU (*Bul. Écon. Indo-Chine, n. ser., 9 (1906), No. 57, pp. 974-998, figs. 15*).—The culture, preparation for market, commerce, and use of this plant are discussed, and a botanical account of different species is given.

Flax culture, H. L. BOLLEY (*North Dakota Sta. Bul. 71, pp. 139-216, pls. 22*).—This bulletin is a treatise on methods of flax culture, soil characteristics, and methods of handling the crop in the United States, Holland, Belgium, Germany, Russia, Austria, and Hungary.

The conditions and prospects of flax culture in the United States are discussed and methods for the improvement of the flax industry in America recommended. The European explorations and investigations by the author were made for the purpose of obtaining new varieties and strains of flax adaptable to differences in soil and climate and possessing greater resisting capabilities to flax wilt and other diseases affecting flax culture. Each step in the culture of the crop, as well as in its preparation for spinning and weaving purposes in the different countries visited, is described in detail.

For the improvement of flax growing in this country the author recommends the use of home-grown seed graded to a bright, plump type and treated with a solution of 1 lb. standard 40 per cent formaldehyde in 40 gal. of water. He fur-

ther advises the practice of crop rotation, including at least two cultivated crops and two or more years in grass and pasture, avoiding the use of poorly composted barnyard manure containing flax straw and never to employ plows, harrows, and other tools used on wilt-infected land in working healthy soil.

The extension of jute cultivation in India, R. S. FINLOW (*Agr. Research Inst. Pusa [India] Bul. 3, 1906, pp. 46, maps 3*).—This bulletin is a report on a tour made for the purpose of investigating the possibility of extending the cultivation of jute to areas outside of Bengal. The conditions favorable for jute cultivation are summarized as a high temperature, a deep soil of fairly fine texture, a rainfall of over 40 in. so distributed that the young plants have plenty of moisture to grow vigorously, but the bulk of the fall taking place when the crop is more mature, and a sufficient supply of clear water for retting. General directions for cultivating jute are given and the condition of the industry in different sections of India is described.

Mineral matter in the lower parts of oat stems in its relation to lodging, D. LIENAU and A. STUTZER (*Landw. Vers. Stat., 65 (1906), No. 3-4, pp. 253-263*).—A review of work previously noted (E. S. R., 15, p. 769), with the results given in a concise form and systematically arranged.

Potato investigations, W. J. GREEN and C. W. WAID (*Ohio Sta. Bul. 174, pp. 251-289, figs. 18*).—The work here reported consisted of spraying and seed selection experiments and variety tests.

Among the 150 varieties grown in 1905, Thorburn White Peachblow, Improved Early Rose, Lily White, Uncle Sam, Lee Favorite, Sensation, Miller-Brook, Boyce, Cracker Jack, and Irish Cobbler produced the heaviest yields. Of the varieties tested the past 3 years Thorburn White Peachblow, Uncle Sam, Improved Early Rose, Summers, Early Rose, Whiton White Mammoth, Spring Valley No. 2000, Seedling No. 110, Sensation, and Sweet Home were the highest producers. Admiral Dewey, Boyce, Early Harvest, Early Ohio, Early Trumbull, and Irish Cobbler are recommended for early market varieties, and Carman No. 3, Ionia Seedling, President Roosevelt, Thorburn White Peachblow, Vt. Gold Coin, and W. W. Mammoth for late market sorts. Boyce, Early Ohio, Early Manistee, and Maxima are recommended as early varieties for home use, and President Roosevelt, Thorburn White Peachblow, Vt. Gold Coin, Vornehm, and W. W. Mammoth as late varieties for home use. A number of other varieties also gave good yields, but have not as yet been fully tested.

Of the varieties grown the past two seasons 33 per cent showed susceptibility to and 30 per cent resistance to early blight. It is stated that by selecting seed from hills showing a tendency to resist the early blight a strain may be secured which would be resistant but not immune. Late blight at the station was controlled to a considerable extent by spraying with Bordeaux mixture, the gain from spraying amounting to 36 per cent.

Rice culture in Tonkin, BUI-QUANG-CHIËU (*Bul. Écon. Indo-Chine, n. ser., 9 (1906), No. 55, pp. 781-839, figs. 7*).—A monograph on rice culture in Tonkin describing the different methods practiced in growing, preparing, and marketing the crop, noting the different varieties cultivated and giving statistics with reference to production and consumption of rice in that country.

The influence of fertilizer applications on the composition of the grain of rye, S. DE GRAZIA and S. CALDIERI (*Staz. Sper. Agr. Ital., 39 (1906), No. 6-7, pp. 514-528*).—Experiments were made with nitrate of soda, sulphate of ammonia, chlorid of potash, and sulphate of potash.

The results indicate that apparently the content of ash and fat is not influenced by the use of nitrogenous or potassic fertilizers. Applications of nitrate of soda and sulphate of ammonia increased the percentage of albuminoids, the nitrate of soda being the more effective in this regard. Chlorid and sulphate of

potash exerted a smaller influence on the albuminoid content. Sugar and starch showed but little variation. The amids increased with the use of each of the four substances. Chlorid of potash was most effective in this respect, while the sulphate stood next in influence to nitrate of soda and sulphate of ammonia. Through the action of each of these substances the cellulose content was decreased, chlorid of potash causing the greatest and sulphate of potash the smallest decrease.

Solanum commersoni, L. BUSSARD (*Jour. Agr. Prat., n. ser., 12 (1906), No. 49, pp. 711-713*).—A violet strain of *Solanum commersoni* was compared with Giant Blue potato and the results showed that the *S. commersoni* variety gave a yield 64 per cent greater than the Giant Blue. In other tests here discussed the yielding capacity was also in favor of *S. commersoni*. In one experiment a plant of this strain, planted August 15, had produced 600 gm. of tubers by October 15.

Breeding seedling varieties of sugar cane by means of crossing and chemical selection, J. D. KOBUS (*Meded. Proefstat. Oost-Java, 4. ser., 1907, No. 29, pp. 131-143*).—Experiments were made with the varieties Cheribon and Chumnee, canes of high and of low sugar content of both varieties being crossed in different combinations.

The results indicated that in the heavy plants secured from the high sugar content parents, as well as those secured from the low sugar content parents, the difference in sugar content was about equal to the average difference of all plants in both groups. The seedlings highest in sugar and descending from parents with a high sugar content were heavier than those coming from the low sugar content group. It was further observed that the seedlings of a high sugar content coming from selected plants high in sugar were much more numerous than the seedlings from selected low sugar content parents. This showed that the chances of obtaining seedlings high in sugar content are three times as great in using high sugar content parents as in using low sugar content parents.

The sugar-cane experiment station, T. F. SEDGWICK (*Estac. Expt. Cana Azúcar [Peru] Bols. 1, 2, 3, 4, pp. 42, pls. 4*).—The first bulletin in this collection describes the general working plan of the station, the second points out the technical management of sugar-cane plantations in Peru, the third presents a detailed plan of the lines of work undertaken, and the fourth reports the results of observations on the seed production of sugar cane. The results secured show that seedless canes stand higher in sugar content and purity than seed-producing canes.

Saving the sweet potato crop, G. W. CARVER (*Alabama Tuskegee Sta. Bul. 10, pp. 14, figs. 6*).—Observations made on the methods of storing sweet potatoes indicate that potatoes dug and banked after a long dry period generally kept well, while those dug and banked after and during a rainy season almost without exception kept poorly. It was also observed that if potatoes were cut or broken and the milky juice turned to a dark greenish color when dried in the air they kept poorly, but if the juice dried white and the injury showed a tendency to heal over they kept well.

Directions for harvesting and storing a crop are given. To store sweet potatoes successfully it is recommended that the plants be set out as early in the spring as late frosts permit, to house or bank the crop only when thoroughly ripe, and to avoid all injury in harvesting.

Technical bulletin on the cultivation of tobacco, A. SPLENDRE (*Bol. Tec. Coltiv. Tabacchi [Scafati], 5 (1906), No. 4-5, pp. 172, pls. 59*).—Several types of tobacco and a long list of varieties are described. Abstracts of experiments with tobacco by a number of investigators are given, and the results of investigations at the Royal Experiment Station at Scafati are reported.

A cross between the varieties Salento and Italia ranked lower in burning quality than Kentucky. A reduced development of the leaf was associated with a diminished burning capacity. The burning quality also diminished from the top toward the base of the leaf, and the use of potash as a fertilizer seemed to increase the combustibility of the middle portion of the leaf. The weight per thousand plants and per hectare was greater when 10 leaves were allowed to develop per plant than when from 11 to 13 were left to grow. It is advised to allow 9 or 10 leaves to develop on plants of the cross between the Salento and Italia varieties. The weight of the crop increased with the increase of potash given in the fertilizer, but this increase was not sufficient to cover the expense of the application. The production of a second crop did not cover expenses and indicated the difficulty of maturing plants in the fall.

The typical variety of *Nicotiana tabacum*, G. E. ANASTASIA (*Bol. Tec. Coltiv. Tabacchi [Scufati]*, 5 (1906), No. 1-2-3, pp. 240, pls. 25, figs. 45, dgms. 3).—Descriptions of different types and numerous varieties of tobacco are given and the leaf characters of many of them are noted. In addition the bulletin presents abstracts on experimental work with tobacco carried on in different countries and discussions of the cultural work with tobacco in different tobacco-growing sections of Italy.

Descriptive notes on typical varieties of wheat grown in New South Wales, F. B. GUTHRIE (*Agr. Gaz. N. S. Wales*, 17 (1906), No. 12, pp. 1173-1205, figs. 27).—A list of 28 varieties are described with reference to their characteristics of growth and their milling qualities. The types represented include the Farrer cross-bred wheats, comprising improved soft, weak-flour wheats and strong-flour wheats. A number of durum wheats are also included in the list.

HORTICULTURE.

Laboratory work in plant breeding, R. A. EMERSON (*Ann. Rpt. Nebr. Hort. Soc.*, 37 (1906), pp. 277-282).—The importance of laboratory work in teaching the subject of plant breeding is pointed out and suggestions given on the value of practical work along this line to the student and on the use of material for hybridization such as peas, beans, squash, pumpkins, etc.

Fertilizing garden crops with lime-nitrogen (*Deut. Landw. Presse*, 34 (1907), No. 5, p. 30, figs. 7).—Some data are given showing the results secured in fertilizing onions and cucumbers with lime-nitrogen, either alone or combined with other fertilizers, and on various soils. With onions it proved more efficient in increasing the yields than either nitrate of soda or sulphate of ammonia. With cucumbers any omission of lime-nitrogen in the formula used resulted in decreased yields. It is claimed that lime-nitrogen is as suitable for fertilizing garden crops on all soils except sour moor and sterile sand as any of the usual forms of commercial nitrogen.

A new muskmelon (*Cal. Cult.*, 28 (1907), No. 2, p. 25, figs. 3).—An account is given of a new variety of muskmelon, having a hard shell not unlike that of the Hubbard squash, but less than $\frac{1}{4}$ in. in thickness, of good quality, and especially promising as a winter melon. The melon contains practically no seed cavity, the seeds being embedded in the pulp. The flesh is light yellowish green in color, without fiber, and of an unusually good flavor. It is thought it will be of especial value as a late fall melon long after the casabas are gone, coming into the market about Christmas time, and it is believed that its firm shell will permit of its being shipped all over the United States. The melon has not yet been named.

Chillies or capsicums, W. R. BUTTENSIAW (*West Indian Bul.*, 7 (1906), No. 3, pp. 213-221).—Quite an extensive account is given of the culture of chil-

lies in different countries of the world, with a review of the more recent literature on the subject and specific directions for cultivation.

Study on *Rheum rhaponticum*, U. CRISTOFOLETTI (*Inaug. Diss., Univ. Bern, 1905, pp. 63, pls. 5*).—A brief historical account is given of rhubarb from the standpoint of its use in medicine, with the results of a chemical study of the plant from the standpoint of the druggist.

Horticultural section, W. J. PALMER (*New Zeal. Dept. Agr. Ann. Rpt., 14 (1906), pp. 247-255, pls. 16*).—An outline of the horticultural work carried on during the year at the Momohaki experiment station with different fruits and vegetables. The Northern Spy apple has been found especially desirable as an apple stock because of its fibrous-rooted nature and its total resistance to aphids. Trees which have borne practically no fruit on Paradise stocks when grafted on Northern Spy stocks have borne well every season, and the union has been more perfect than on the Paradise stocks.

Hypodermic injections in plants (*Gard. Chron., 3. ser., 41 (1907), No. 1045, p. 8*).—An account taken from the *Journal de la Société Nationale d'Horticulture de France* is given of the work of J. M. Simon in injecting nutritive fluids into the stems of trees and other plants as a means of rejuvenation. For trees a receptacle containing the fluid to be injected is placed at a height of about 6 ft. above the ground level. From this a pipe is carried down nearly to the level of the soil, to which a funnel-shaped curved tube is attached at the base and made to penetrate the young wood at the roots of the tree. By this means a certain amount of pressure is secured.

The work has been carried on with apples, peaches, vines, and potatoes. In the case of the peach purin was injected mixed with water, as a result of which a decrepit tree was made to grow vigorously. Other materials used were nitrate of potash and certain chemical solutions closely resembling sap in composition. By this method of treatment peach trees that had previously been attacked with blister dropped their leaves and produced new ones which were unaffected by the fungus. A solution of copper sulphate injected into vines resulted injuriously in part, but with the aid of copious waterings the leaves partially recovered, and at the end of the experiment neither *Oidium* nor mildew was to be seen either on the foliage or berries.

A like arrangement was used in injecting fluid into cabbage, cauliflowers, and potatoes, the receptacle containing the liquid being at a height of from 3 to 4 ft. above the collar of the plant, at which place the funnel-shaped cannula was inserted.

The importance of lime as a plant food for seedlings, VON BREHMER (*Gartenwelt, 11 (1907), No. 14, pp. 163, 164, fig. 1*).—The author points out the greater use that seeds in germination and first growth make of lime over potash or phosphoric acid and gives the results of a germination test with seeds of a number of varieties of flowers with and without lime. In every instance a much larger germination percentage was secured where an abundance of lime was present.

Relative to the use of lime it is stated that if quicklime is used it should be applied to the soil at least 8 weeks before the seed is planted. The carbonate, on the other hand, can be applied within a day of planting without injurious results. In any case the lime should be thoroughly well mixed with the soil before the seeds are planted.

Plant breeding in relation to American pomology, W. M. MUNSON (*Maine Sta. Bul. 132, pp. 149-176*).—A brief account is given of the methods of work heretofore employed in plant breeding as related to the development of American fruits. The results accomplished up to the present time in breeding straw-

berries, grapes, pears, apples, plums, blackberries, etc., are noted and a number of the unsolved problems now confronting American pomologists mentioned. The author holds that the practice of propagating our common fruits as followed by most nurserymen is radically wrong, tending to deterioration of varieties rather than to improvement, since buds are often selected promiscuously from either bearing or barren trees and from nursery stock of unknown character.

Results from work in breeding hardy fruits, C. G. PATTEN (*Ann. Rpt. Nebr. Hort. Soc., 37 (1906), pp. 269-273*).—The author began breeding hardy fruits, particularly apples, in the West about 1869. An account is given of this work, resulting in the production of the Patten greening apple and the securing of many important seedling apples of large size and good quality. The author has been able to secure a cross between the native Souldard crab and a Pippin apple.

Crop improvement by utilizing wild species, C. E. BESSEY (*Ann. Rpt. Nebr. Hort. Soc., 37 (1906), pp. 116-123*).—In securing new crops for agricultural purposes from wild plants the author calls attention to the value of our various species of native grapes, wild wheat grasses, wild barley, blue grama grass, bird-foot clover (*Lotus americanus*), buffalo peas (*Asragalus crassicaepus*), tomato cherries (*Solanum triflorum*), ground nuts (*Apios apios*), prairie apple (*Malus ioensis*), dwarf wild cherry (*Prunus demissa*), Nebraska sand cherry (*P. besseyi*), buffalo berry (*Lepargyrea argentea*), low sumach (*Rhus trilobata*), and hawthorns.

A curious effect of grafting by approach, A. NOMBLOT (*Jardin, 20 (1906), No. 476, pp. 373, 974, fig. 1*).—An account is given of grafting by approach the variety of pear Mme. Chaudy on Beurre Superfin. A branch on the stock coming out below the graft produced fruit similar in form and qualities to that produced on the scion, due it is thought to the reciprocal action of the scion. An illustration is given showing this similarity in form of the fruit.

Fruit varieties most popular on the Pacific Slope, E. J. WICKSON (*Pacific Rural Press, 72 (1906), No. 25, p. 392*).—The author sent a circular of inquiry to nurserymen throughout the State of California as to the most popular varieties of fruits they were propagating. The answers to these have been tabulated for apples, apricots, cherries, grapes, peaches, pears, plums, and prunes.

Peach growing in Texas, E. J. KYLE (*Texas Sta. Bul. 80, pp. 29, figs. 15*).—Detailed directions with numerous illustrations are given for all the various phases of peach culture as observed in Texas.

Relative to the cropping of young peach orchards the author states that the results of two years' tests at the station indicate the following rotation as best: An early maturing crop that will come off the land about June 1, followed by cowpeas, peanuts, sweet potatoes, or some crop that will mature late in the summer. After the first crop is taken off the soil is thoroughly broken and pulverized and the soil on each side of the trees kept stirred until about September 1.

"The advantage of planting such crops as Irish potatoes, tomatoes, etc., is that the soil is well fertilized, having more plant food added than is removed by the crop. Then again these crops come off early, so that the soil can be gotten in fine condition before the second crop is put on. By this method the soil is kept stirred throughout the summer and the trees are kept going until September."

Olive pickling, F. T. BIOLETTI (*California Sta. Circ. 24, pp. 14, figs. 12*).—A discussion is here given of the value of olives as food, with details of the best methods of gathering, sorting, grading, pickling both ripe and green olives,

and preserving by heating, with an account of varieties best suited for the different purposes. The bulletin is based on earlier publications of the station (E. S. R., 14, p. 441).

Growing oranges forty years, H. M. STRINGFELLOW (*Texas Farm and Ranch*, 25 (1906), No. 51, p. 11).—The author has grown oranges in southern Texas since 1865, and in this article gives the results of his experience during the time. Generally speaking, the results have been unfavorable, as about the time the trees were coming into bearing they were killed by exceptionally cold winters. The dates of these various killing winters are recorded in some detail.

Date palm, F. FLETCHER (*Dept. Land Rec. and Agr. Bombay, Bul. 28, pp. 17*).—The object of this publication is to encourage the culture of the date palm in India.

Detailed discussion is given of the conditions necessary for the culture of the date palm, with an account of the attempts that have been made in India to improve and extend its culture, including the present aspect of the situation. Besides a discussion of all the usual cultural details, tabular data are given for a large number of well-known varieties as regards production, name of variety, time of ripening, soil required, principal markets, etc.

Mangoes, J. B. BEACH (*Fla. Agr.*, 33 (1906), No. 47, p. 793).—The author gives his experience extending over a number of years in grafting and budding mangoes. Contrary to the results secured by Oliver, who prefers budding (E. S. R., 16, p. 365), he has found inarching with pot-grown trees the only practical method of propagating nursery stock.

California crop statistics 1905-6 (*Cal. Fruit Grower*, 34 (1906), No. 963, p. 5).—The almond yield for the year 1905-6 is placed at 2,100 tons, beet-sugar output 64,210 tons, brandy production 4,070,992 gal., canned fruit and vegetable pack 4,475,751 cases, citrus fruit shipments 27,610 cars, cured fruit and raisin output 120,700 tons, honey yield 10,000,000 lbs., hop crop 73,000 bales, prune output 62,500,000 lbs., raisin yield 90,000,000 lbs., vegetable shipments 67,900 tons, walnut yield 6,400 tons, and wine production 26,502,310 gal. The entire issue of the *Fruit Grower* is devoted to a review of the production of different crops in California and, in some cases, elsewhere during the year 1905-6.

Cocoanuts, P. HUBERT (*Le Cocotier. Paris: H. Dunod and E. Pinat, 1906, pp. XIII+133, figs. 39*).—A popular treatise on the establishment of coconut groves, coconut culture, and the production of copra, coconut oil, dried coconut, fiber, etc., with descriptions of the various forms of machinery used in preparing different coconut products for market.

The cacao plantation in French Congo, C. CUMLOT and M. LUC (*Le Cacaoyer au Congo Français. Paris: Bibliothèque D'Agriculture Coloniale, 1906, pp. 59, figs. 35, map 1*).—A discussion of the commercial importance of cacao to the French colonies, and an account of its culture in French Congo.

The importance of shade trees in cacao culture, C. J. J. VAN HALL (*Inspectie Landb. West-Indië, Bul. 7, pp. 20*).—An extended account, based on the results of observation and experiments, is given of the importance of shade in cacao culture.

The value of shade is attributed to a number of factors, the more important of which are the keeping of the ground cool, the preservation of the soil moisture, better physical condition of the soil brought about by the decaying leaves and the growing roots of the trees, and the greater fixation of nitrogen in the soil. The shade trees are also of value as a windbreak.

The general conclusion is drawn that cacao trees will flourish in full sunlight and give increased yields, but in that case all of the benefits which arise

from shade must be supplied by the use of some intercultural crop or by manuring. The question as to the better method of culture from a practical standpoint, therefore, resolves itself into which method is the more economical in any particular case.

The varieties of cultivated pepper, C. A. BARBER (*Dept. Agr. Madras Bul.* 56, pp. 123-133, pls. 3).—A botanical account is given of the principal species and varieties of cultivated black pepper vines. The 3 main types of good vines are the Balamcotta, Kallivalli, and Cheriakodi. These classes with the several varieties coming under each are described. Plates are also given showing pepper flowers and fruits of the different classes.

Every farmer can raise evergreens, C. S. HARRISON (*Twentieth Cent. Farmer, 1907, No. 317, p. 9, figs. 3*).—As a result of 35 years' experience in the semi-arid regions of the West the author states that in growing seedlings of the ponderosa or bull pine, the best results are secured if they are grown in the open sunlight. If grown under screens they are likely to damp off and it is difficult to get a good stand.

Generally speaking, the seed should be sown in the fall, but spring sowing can be made if the seed is first soaked in warm water, the water being changed every 12 hours and the seed kept in a warm place. Thus treated, the seed will sprout within 3 or 4 days, when it should be planted in a well-prepared bed and covered with an inch of sand or fine earth. The soil must be kept moist until the plants come up.

Seed two or three years old has been found as satisfactory as new seed. About a pint is used to each 8 feet square of bed surface. In digging up the trees he advises that the roots be obtained full length. Fair success has been obtained by digging the trees from the seed beds when 4 years old, but preference is given to plants 1 to 2 years old.

The action of ether in forcing plants (*Amer. Florist, 27 (1906), No. 968, pp. 1051, 1052*).—This is a translation of an article taken from *Revue Horticole* giving an account of 5 different experiments in the use of ether for forcing plants.

In preparing lilacs for forcing it is stated that they are dug up about October 15, when the buds are well formed, with a ball of earth attached and left in the open if the weather be dry, or put under sheds if it rains. In either case, the leaves are left upon the branches. After 2 to 4 days, when the plants wilt and the bark begins to wrinkle, all the leaves are cut off, leaving the stems, which are not easily removed. The plants are stored 7 or 8 days in a dry place and then taken into the greenhouse for forcing.

Generally speaking, the action of the ether was found to vary greatly, depending upon whether the plants were rested or not. With rested plants etherization hastened the blooming period but a few days, while with non-rested plants it reduced the forcing period by half and gave far better blooms.

At a temperature of 60° and a dry atmosphere 3 to 4 oz. of ether per cubic yard was found sufficient, while in a moist atmosphere up to 8 oz. was used with impunity. The duration of the etherization process should correspond with the time necessary for a complete evaporation of the ether used. In a dry atmosphere the temperature should not be over 60 to 65°, but if the air is moist, 70 to 77° is not too warm.

Etherization appears to be most effective with lilacs. Much less favorable results were secured with snowballs, *Azalea mollis*, and *Deutzia gracilis*. In 3 tests with lily of the valley, the first growth appeared quite rapid, but the blooming period was in no case hastened more than 48 hours.

FORESTRY.

Forest planting in eastern Nebraska, F. G. MILLER (*U. S. Dept. Agr., Forest Serv. Circ. 45, pp. 32*).—A study was made of the forest plantations in eastern Nebraska to ascertain the species of trees best suited for planting throughout the region. The plantations already in existence were studied with reference to their silvicultural requirements, the amount and value of wood products grown, and the effect of different methods of planting.

The planting of forests has decreased in eastern Nebraska in recent years, and some of the earlier planted forests are being cut off. Tables are given showing the height and diameter growth of the principal species of trees planted in eastern Nebraska over a period of 50 years, the amount of heart wood in trees of various diameters, and the yield of cottonwood on bottom land and on upland, as well as the yield of catalpa, green ash, black walnut, honey locust, osage orange, white willow, silver maple, box elder, Russian mulberry, white elm, Lombardy poplar, black locust, and various other species of broad-leaf trees and of pines.

The data obtained show that hardy catalpa, osage orange, black walnut, cottonwood, white willow, green ash, and honey locust can be grown with profit in eastern Nebraska. "Hardy catalpa, osage orange, and green ash should be planted chiefly for fence posts, white willow for fuel, black walnut for lumber, and cottonwood for fuel and lumber. All attain their best development in rich, well-drained valleys. Cottonwood, white willow, and black walnut are essentially bottom-land trees. Osage orange should be planted on upland only in fertile soils in southeastern counties. The range of hardy catalpa in upland planting is considerably wider, but it must have good soil. Green ash and honey locust are especially adapted for dry upland planting in the more western and southwestern counties. . . . In the sand hills some of the conifers, such as western yellow pine and jack pine, undoubtedly may be planted with profit, since land values are certain to remain low."

Holding force of railroad spikes in wooden ties, W. K. HATT (*U. S. Dept. Agr., Forest Serv. Circ. 46, pp. 7, figs. 4*).—Tests were made to compare the relative holding force of common, channeled, and common screw spikes, and Illinois Central screw spikes, when driven into railroad ties of both hard and soft woods in different states of seasoning and when treated with preservatives. The common spikes weighed 165 to the 100 lbs., common screw spikes 85 to the 100 lbs., channeled spikes 200 to the 100 lbs., and Illinois Central screw spikes 85 to the 100 lbs. The results of the tests are given in tabular form.

As regards the common screw spikes the tests show that they resisted withdrawing with from 2 to 3 times the force of the common spikes, the resistance being most marked in the softer woods. In soaked loblolly pine the channeled spikes had about 60 per cent of the holding power of screw spikes and about 12 per cent more holding power than common spikes. The common screw and Illinois Central screw spikes had practically the same holding power in loblolly pine.

The holding power of seasoned ties was found to be greater than that of steamed ties. With common spikes knotty ties had about 25 per cent less holding power than clear ties. With the screw spikes, on the other hand, a knotty tie had 35 per cent greater holding power than a clear one. The holding power of a natural tie and of one steamed for 4 hours at 30 lbs. pressure was found to be about the same. "Steaming for 4 hours at less than 30 lbs. appears to increase the holding power, while steaming for more than 4 hours at 20 lbs. decreases it. Ties steamed and creosoted or steamed and treated with zinc chlorid appear to have less holding power than those simply steamed."

Strength of packing boxes of various woods, W. K. HATT (*U. S. Dept. Agr., Forest Serv. Circ. 47, pp. 8, figs. 5*).—The merits of Michigan white pine, New England white pine, loblolly pine, western spruce, western hemlock, cottonwood, and red gum as box material were tested.

The lumber used was of average quality, containing about 11 per cent moisture with only sound, live knots, and without sap stains. Three sizes of boxes were made up—large, holding up to about 600 lbs. of dry goods; medium, corresponding to those used for hardware, soap, or canned goods, up to 250 lbs., and small, holding up to 100 lbs. Four styles of boxes were also used, (1) plain without battens, (2) four square battens on each end, (3) four bevel battens on each end, and (4) two battens on each end. In testing, the load was applied along the diagonal of the box, an action similar to that which occurs when the box is dropped on one of its corners. In case of small boxes the load was also applied along the entire length of the edge of the box.

The results of the tests show that of the woods tested "cottonwood was the strongest for medium and large boxes and red gum for boxes of small size. For all sizes cottonwood and red gum occupied the first two positions in regard to strength. The weakest wood differed for each kind of box. For the large size it was western spruce, for the medium size Michigan white pine, and for the small size North Carolina pine." When, however, the strength of the boxes per unit of weight was considered the cottonwood as before stood first, white pine standing second for boxes of large size. For small size, however, cottonwood, red gum, western spruce, and western hemlock showed greater strength than white pine.

The experiments also showed that thin end boards could not be substituted for end boards of standard thickness without reducing the strength of the box. With small boxes of New England pine the strength of lock-cornered boxes exceeded that of dovetailed boxes, while the latter were stronger than nailed boxes. Other tests showed that the majority of nails at the end of the side, top, and bottom boards should be driven into the end boards rather than into the battens.

Kiln-drying hard-wood lumber, F. DUNLAP (*U. S. Dept. Agr., Forest Serv. Circ. 48, pp. 19, figs. 4*).—The author describes the systems of kiln-drying hard-wood lumber generally in vogue in this country, discussing at considerable length the theory of drying, and points out a number of unsolved problems in this industry. The report is based on work with white oak, red oak, maple, birch, basswood, chestnut, ash, red gum, mahogany, cherry, and walnut.

It was found that the time consumed in kiln-drying these woods varies greatly among different operators. White oak, for instance, is generally dried from 1 to 2 weeks, yet some operators double this period, and others reduce it to from 3 to 5 days. The length of time that each species should be dried varies widely with a number of conditions. Thus "quarter-sawed oak usually requires half again as long as plain oak, mahogany requires about the same time as plain oak, ash dries in a little less time, and maple, according to the purpose for which it is intended, may be dried in one-fifth the time needed for oak, or may need a slightly longer treatment. For birch the time required is from one-half to two-thirds and for poplar and basswood from one-fifth to one-third as long as that required for oak."

The cost of kiln-drying among different operators was found to be from 75 cts. to \$5 per thousand feet.

It appears from the investigations that dry kilns are constructed and operated at the present time largely without careful system. Many of the present defects in kiln-drying resulting in warping, twisting, checking, case-hardening,

and honeycombing are pointed out, and the principles to be followed in constructing kilns are laid down. Broadly speaking, a system of heaters and radiators in a rightly constructed kiln should be capable of maintaining the desired temperature at all times. "The temperature and humidity of the drying chamber should be under perfect control and protected from outside influences. Simple devices should control the circulation as desired, both between the kiln and the outer atmosphere and between the two ends of the kiln. Toward the end of the process abundant and vigorous circulation should be provided for, due care being taken not to lower the temperature."

The subjects of moist-air drying, preliminary seasoning, preliminary use of steam in the kiln, prolonged submersion of the wood in water, etc., are also discussed.

Timber used in the mines of the United States in 1905, R. S. KELLOGG (*U. S. Dept. Agr., Forest Serv. Circ. 49, pp. 8*).—Of 14,000 mines to which inquiries were sent regarding the use of timber, 5,000 reported that timber was used and nearly 9,000 reported no use of timber.

From the data obtained, which it is calculated covered fully 90 per cent of the total amount of timber used during the year, a total of 165,535,900 cu. ft. of round timber and 435,944,000 board feet of sawed timber is shown. Or if the round timber be reported in board feet the total for use in mines would be 2,422,374,800 board feet. The quantity of timber used in the different kinds of mines, such as bituminous and anthracite coal, iron mines, and mines for precious metals, is shown for each of the different woods in tabular form. The principal mine timbers, both round and sawed, are pine and oak. The total cost of the timber used during the year was \$16,500,000.

The States in which the cost of mining timber exceeded \$500,000 are Pennsylvania, Montana, Arizona, Illinois, Michigan, West Virginia, Colorado, and California.

Wood used for distillation in 1905, H. M. HALE (*U. S. Dept. Agr., Forest Serv. Circ. 50, pp. 3*).—Statistics secured from 82 distillation plants in the United States are given, showing the amount of wood used and the products produced. The total amount of wood used was 676,739 cords, resulting in 26,670,139 bu. of charcoal, 5,062,076 gal. of alcohol, 86,685,129 lbs. of acetate of lime, 238,180 gal. of turpentine, and 1,039,980 gal. of tar and oil, besides 434,780 gal. of oil from pine distillation. The chief States in which woods are used for distillation purposes are Pennsylvania, Michigan, and New York. The quantity of pine distilled and its products were insignificant when compared with those of hard-wood, there being but 16,969 cords of pine distilled.

Wood used for veneer in 1905, H. M. HALE (*U. S. Dept. Agr., Forest Serv. Circ. 51, pp. 4*).—Data received from 128 manufacturers of veneer in the United States were compiled for the year 1905.

More than 189,000,000 ft. log measure is used for veneering purposes. Of the veneer stock produced in 1905 21.8 per cent was made from red gum, 14.5 from maple, 14.4 from yellow poplar, 9 from cottonwood, and 8.9 from white oak. About one-third of the establishments used no artificial process in drying. Thirty-nine establishments used the cores from the rotary process in veneer making for fuel, and 33 converted them into excelsior. In one instance they were used for pulp, in another for porch posts, and in others for crates, boxes, and baskets.

The lumber cut of the United States in 1905, S. R. KELLOGG (*U. S. Dept. Agr., Forest Serv. Circ. 52, pp. 23, figs. 3*).—Statistics for the lumber cut in the United States in 1905 were secured through cooperation with the National Lumber Manufacturers' Association and other lumber associations by correspondence.

The data secured show that 11,666 establishments cut 30,502,961,000 ft. of

lumber in 1905. In recent years there appears to be a decrease in the number of lumber establishments, with a gain in the individual output. The largest amount of lumber was furnished by yellow pine, followed by white pine, Douglas fir, hemlock, white oak, spruce, etc.

The amount of lumber produced by all the different species of trees in the various States is given in detail in tabular form, from which it appears that Arkansas leads in the production of red gum and cottonwood, California in western yellow pine and redwood, Idaho in western white pine, Indiana in hickory and walnut, Kentucky in yellow poplar, Louisiana in yellow pine and cypress, Maine in spruce and balsam, Michigan in maple, beech, and ash, Minnesota in white pine, Montana in larch, Pennsylvania in hemlock and chestnut, Tennessee in red oak, West Virginia in white oak, and Wisconsin in basswood, birch, elm, and tamarack.

The shingle cut in 1905 by 2,547 mills was 15,340,909,000, and the total lath cut in 1905 by 1,801 mills was 3,111,157,000.

Notes on the influence of forests on the storage and regulation of the water supply, S. EARDLEY-WILMOT ([*Indian*] *Forest Bul.* 9, pp. 58, pls. 3).—A summary is given of European research into the interrelation between forests and rivers, with a discussion of the application of results of European research to Indian conditions. Heretofore the forests of India have been managed without special reference to water supply and stream flow. The great desirability of considering this phase of the subject is pointed out at length. In the appendix the principal rivers of India are noted and extracts given from the proceedings of the American Forest Congress in 1905.

Forest litter and nitrogen, HORNBERGER (*Ztschr. Forst u. Jagdw.*, 38 (1906), No. 12, pp. 775-781).—Further experiments are reported by the author (E. S. R., 17, p. 564) to determine whether decaying leaves in forests are able to increase their total nitrogen content by fixation of a certain amount of the free nitrogen of the air. The materials used were oak and hornbeam leaves. Data obtained in 8 different experiments are tabulated and the conclusion is drawn from the work that it is now certain that forest litter under favorable conditions can actually increase its nitrogen content by fixation from the free nitrogen of the air.

The effect of the moon's phases on the period of felling bamboos, E. P. STEBBING (*Indian Forester*, 32 (1906), No. 11, pp. 534-540).—It is commonly held by the natives of India that the felling of export bamboos or of poles should not be done when the moon is full, as otherwise, unless well soaked in a tank and subsequently well preserved by smoke they will be rapidly destroyed by boring insects, the most serious of which are *Dinoderus pilifrons* and *D. minutus*.

Four experiments are recorded in which bamboos were cut for a few days before and after the new moon and full moon and at different seasons of the year. In at least three of the experiments the results seemed to show that the season of cutting, whether before, during, or after full moon, had no effect on the susceptibility of the bamboos to the attacks of beetles.

Other results were secured which indicate that the cold weather months are the best ones in which to fell, the attacks of the borers being much less at this season, and further that bamboos stacked in the shade and covered up in such manner as still to allow the beetles getting at them were more severely attacked than those stacked in the open. The author believes that if bamboos are felled during November and the first half of December and immediately piled or stacked in the sun they will not be attacked by the borers.

Note on the chilgoza forests of Zhob and the Takht-I-Suliman, E. P. STEBBING ([*Indian*] *Forest Bul.* 7, pp. 35, pls. 6, map 1).—The author, while investigating the attacks of bark-boring beetles which were devastating the

chilgoza forests in Baluchistan, made extensive notes on the general character of the chilgoza forests of Zhob and of the Takht-I-Suliman, and advocates that these forests be protected by the government. The forests are described and a map given of them, with an account of the forest growth, and suggestions for their better management.

Caoutchouc in Indo-China, C. and A. SPIRE (*Le Caoutchouc en Indo-Chine*, Paris: A. Challancl, 1905, pp. VIII+262, pls. 35, map 1).—Part 1 of this work is devoted to the botany of the caoutchouc-producing plants of Indo-China; part 2 to a study of the chemistry and industrial uses of the caoutchouc from different species, and an account of methods of harvesting and of the commercial importance of the industry. The appendix contains various tables showing the value of different moneys, weights and measures, etc., with a bibliography of over a hundred papers on the subject.

Contribution to the chemistry of gutta-percha and caoutchouc, O. MÜLLER (*Inaug. Diss., Univ. Bern, 1905*, pp. 87, figs. 6).—This paper presents the results of extensive investigations into the chemical nature of gutta-percha and caoutchouc.

DISEASES OF PLANTS.

Plant diseases in Bulgaria, K. MALKOFF (*Ztschr. Pflanzenkrank.*, 16 (1906), No. 4, pp. 212, 213).—An abstract of a report of the royal agricultural experiment station at Sadovo, Bulgaria, the second part of which is taken up with studies of the various plant diseases.

Results are given of experiments for the prevention of grain smuts, in which the grain was treated with hot water, Bordeaux mixture, copper sulphate solution, formaldehyde, and dry air. The most efficient treatments were those in which formaldehyde was used.

In examining the susceptibility of the native varieties of wheat to smut the author reports that the hard wheats (*Triticum durum*) were most attacked, as much as 83 per cent being smutted, while the soft wheats ranged from 26 to 44 per cent. It was also found that neither late nor early seeding had any effect on the amount of smut present.

In continuation of his investigations on the bacterial disease of sesame (E. S. R., 17, p. 1166), the author reports that 2 species of bacteria are present. Soaking the seed in a 0.1 per cent solution of formaldehyde for 4 hours was found to have an excellent effect in preventing this disease.

Notes are given on the attack of chick-peas by *Ascochyta pisi*, which may be controlled by spraying with a 1 per cent solution of Bordeaux mixture, and on the leaf curl due to *Eroscaeus deformans*, which may be prevented by spraying with a 3 per cent solution of Bordeaux mixture. A bacterial disease of mulberries and a new disease of plums, which is causing considerable injury, are subjects for further investigation.

Report of the section of plant protection of the Royal Servian agricultural chemical experiment station at Belgrade, 1903-1905, N. RANOJEVIĆ (*Ztschr. Pflanzenkrank.*, 16 (1906), No. 4, pp. 207-212).—In 1902 there was established in connection with the agricultural chemical experiment station of the ministry of agriculture a section for plant protection, and the present is the first report of the investigations carried on by this section.

One of the principal subjects investigated has been the downy mildew of grapes (*Plasmopara viticola*), for combating which experiments have shown that spraying with Bordeaux mixture has proved efficient. Notes are given on a number of other fungus diseases and insect enemies of economic plants.

Agricultural botanical report for 1906, J. ERIKSSON (*K. Landtbr. Akad. Handl. och Tidskr.*, 45 (1906), No. 3-4, pp. 237-298).—Descriptions of the fol-

lowing plant diseases which have recently appeared in Sweden are given, with directions for eradicating or combating them: American gooseberry mildew (*Sphaerotheca mors-urae*), American grape mildew (*Oidium Tuckeri*), cabbage club root (*Plasmodiophora brassicae*), eelworms on oats (*Tylenchus devastatrix*), leaf mildew on briar roses (*Peronospora sparsa*), and raspberry blight. The report also contains a discussion of the vegetative life of grain rust fungi in the growing plant, and of international cooperation for protection against and the combating of plant diseases. A summary of experiments completed during the year, or in progress, at the Royal Agricultural Academy of Sweden, and a list of publications for the year complete the report.—E. W. WOLL.

Report of the government botanist, C. A. BARBER (*Rpt. Dept. Agr. Madras, 1905-6, pp. 43-48*).—In addition to the routine report relating to collections, economic plants, etc., the author briefly describes some fungus diseases of sugar cane, peppers, peanuts, and Palmyra palms.

A study of some species of Fusarium and the plant diseases they cause, O. APPEL and G. SCHIKORRA (*Arb. K. Biol. Anst. Land u. Forstw., 5 (1906), No. 4, pp. 155-188, pl. 1, figs. 3*).—The results of a study of Fusarium diseases of a number of leguminous plants are given.

The St. John disease of peas, which has previously been noted (E. S. R., 15, p. 375), is described at some length, particular attention being given to the morphology, physiology, and chemical relations of the organism, which is recognized as *Fusarium vasinfectum pisi*.

Other wilt diseases of leguminous plants are more briefly described, among them a wilt of lupines and a Fusarium disease of vetch. The lupine disease is said to be caused by a form of *F. roseum*, and a technical description of the organism is given.

A summary of preventive treatments is given which includes care in selecting seed, avoiding the use of poorly germinating seed, the complete destruction of infected plants when observed, cultivation of resistant varieties, and the rotation of crops.

Monograph of the genus Ravenelia, P. DIETEL (*Bot. Centbl., Beihefte, 20 (1906), 2. Abl., No. 3, pp. 343-413, pls. 2*).—This is a monograph of the genus Ravenelia, a group of fungi parasitic on various species of euphorbiaceous and leguminous plants. The author notes the morphology of the fungi, their life history, geographic distribution, etc., after which he describes the 81 recognized species. A list is given of a number of isolated uredo forms which the author thinks probably will be ultimately found associated with species of Ravenelia.

A new fungus of cereals, J. R. JUNGNER (*Ztschr. Pflanzenkrankh., 16 (1906), No. 3, pp. 131-135, pl. 1*).—The author reports observing numerous sclerotia of a fungus on the leaves of winter rye and wheat. Subsequent studies revealed the fruiting bodies of the fungus, which proved to be hitherto undescribed. The fungus seems to be associated with attacks of *Hylemyia coarctata*, one of the wheat flies. A technical description of the fungus (*Psilocybe hemmingsii* n. sp.) is given.

Wheat mildew, C. T. MUSSON (*Agr. Gaz. N. S. Wales, 17 (1906), No. 12, pp. 1222-1224, fig. 1*).—The author reports having observed considerable injury to wheat in Australia, which is due to the mildew *Erysiphe graminis*. This fungus is well known on a number of species of grass, but this seems to be the first report of its occurrence on wheat in Australia. The variety Federation seems to have been badly attacked, as upon the diseased plants no grain was formed and the straw was rendered almost useless.

Some experiments on the germinative ability of old ergot sclerotia, ZIMMERMANN (*Ztschr. Pflanzenkrankh., 16 (1906), No. 3, pp. 129-131*).—Studies were

made both in the greenhouse and in the open air to determine the germinative ability of old sclerotia of the common ergot (*Claviceps purpurea*).

It was found that sclerotia more than 2 years old had lost all power of germination. Those remaining dormant the first year germinated readily the second year and at about the same time as fresh sclerotia. Moldy and broken sclerotia often retain a high percentage of their viability. Contrary to the popular belief that ergot must be kept moist over winter or it will not germinate, the author found that neither sowing in dry soil nor keeping the sclerotia in glass jars until time for experimental sowing diminished their germinative ability.

The time at which the development of promycelium and conidia takes place is approximately the same every year and corresponds with the normal flowering period of the cereals on which the fungus is a parasite.

Potato diseases, E. LANGE (*Die Kartoffelkrankheiten*, Leipzig: O. Schöndcker, 1905, pp. 12, figs. 3, charts 3).—This is a brief descriptive guide to accompany the colored charts which illustrate various diseases of potatoes, among them the potato rot, black shank or stem rot, leaf curl, scab, wet and dry rot of tubers, bacterial rot, nematodes, etc.

A contribution to the knowledge of potato scab, H. T. GÜSSOW (*Ztschr. Pflanzenkrankh.*, 16 (1906), No. 3, pp. 135-137, pl. 1).—A discussion is given of the form of potato scab that has been variously referred to as *Rhizoctonia violacea* and *R. solani* (E. S. R., 14, p. 159; 16, p. 788; 18, p. 151). The author claims that these 2 species of *Rhizoctonia* are identical, and from his own observations and those of Rolfs (E. S. R., 16, p. 788), he is convinced that the perfect form of the fungus is *Corticium vagum solani*.

A bacterial rot of the potato caused by *Bacillus solanisaprus*, F. C. HARRISON (*Centbl. Bakt. [etc.]*, 2. Abt., 17 (1906), Nos. 1-2, pp. 34-39; 3-4, pp. 120-128; 5-7, pp. 166-174; 11-13, pp. 384-398, pls. 8).—The bacterial rot of potatoes has been more or less prevalent in the province of Ontario during the past 5 or 6 years and was particularly troublesome in 1904 and 1905. This disease resembles somewhat that described as being rather widespread in Germany and which is also known in England under the name of black shank disease (E. S. R., 15, p. 374).

Usually the first symptoms of the disease appear when the plants are in full vigor of growth, when a plant here and there in the field presents a sickly appearance, with drooping leaves somewhat discolored or yellowed. In a few days the stems lose their erect appearance and gradually fall to the ground, the whole stem and leaves finally shriveling up. When the leaves are turning yellow, black areas may be seen on the stems and petioles; and if these are cut through, the vibrovascular bundles and adjacent tissues will be found black or brown, depending on the progress of the disease. The stems are usually most discolored or blackened near the ground, but sometimes the discoloration is higher up the stem.

The tubers show the most characteristic indications of the disease, and when the plant appears to be in a fairly healthy condition the tubers may be badly diseased. Potatoes which appear sound if carefully examined will show discolored areas somewhat like a bruise, and as the disease progresses the flesh beneath the darkened portion becomes soft. On breaking the skin a white turbid liquid can be pressed out, which rapidly turns black on exposure to the air. In later stages of the disease the flesh softens to a watery pulp and becomes highly offensive, with a putrefactive odor. If potatoes are dug and stored in cellars or pits the disease continues to spread.

The author has found constantly associated with this disease an organism to which the name *Bacillus solanisaprus* is given. This has been isolated,

and its morphological and biological characters, as shown in pure cultures in various media, are described at considerable length.

Inoculation experiments have been made on a number of plants in addition to the potato, and it was found to successfully inoculate the tomato, ground cherry, peppers, and cucumber, but failed to produce any results, the wounds quickly healing on the eggplant, thorn apple, petunias, and a number of other plants more or less related to the potato.

The disease seems to be quite prevalent throughout Canada, and in 1905 it is estimated to have caused losses amounting to \$720,000.

Investigations show that undoubtedly the principal means of infection comes from the diseased condition of the seed potato when planted. If the organism is in the soil, infection apparently may be produced through the seed tuber, and infection may also be produced through wounds, as has been repeatedly demonstrated. The moisture of the atmosphere and soil are shown to be conditions which influence the spread of the disease.

It has been found that certain varieties of potatoes under field conditions are more immune than others, and as methods of prevention the author suggests the planting of rot-resistant varieties, the use of seed potatoes that are free from disease, planting in well-drained land, reducing insect injury by the use of Paris green or other insecticides, preventing the growth of fungi by the use of Bordeaux mixture, and, finally, the rotation of crops.

The heart rot of beets, MERLE (*La Maladie du Cœur de la Betterave. Joigny: Hamelin, 1906; rev. in Prog. Agr. et Vit. (Ed. l'Est), 28 (1907), No. 1, pp. 26, 27.*)—An account is given of a disease of sugar beets which is attributed to *Phoma tabifica* or *P. beta*.

This disease it is said usually makes its appearance in the field between the middle of July and the end of August when here and there may be seen leaves which present a wilted appearance, as is frequently observed on a very hot day. The next morning the leaves instead of having a refreshed appearance are still wilted, and if examined the petioles will be found to be brown spotted, and the leaves finally die. Later the disease becomes quite evident on the root, ultimately causing its destruction.

The disease seems most frequent on sandy clay soils, and for combating it deep culture, particularly during the fall and winter, the application of wood ashes, long periods of rotation, and the planting of resistant varieties are recommended.

Sclerotinia libertiana as the cause of the rotting of root crops, O. APPEL and W. F. BRÜCK (*Arch. K. Biol. Anst. Land u. Forstw., 5 (1906), No. 4, pp. 189-203, figs. 7.*)—An account of the rotting of various root crops in cellars and storage pits, the injury being attributed to the presence of the fungus *Sclerotinia libertiana*. Descriptive notes are given on the fungus and a report made on the investigations regarding its host plants and methods for preventing its occurrence and spread in storage.

A grass-destroying myxomycete, T. WULF (*Ztschr. Pflanzenkrankh., 16 (1906), No. 4, pp. 202-206, pl. 1.*)—An account is given of severe injury to various species of grasses by *Physarum cinereum*.

The clover broom rape, E. MARRE (*Prog. Agr. et Vit. (Ed. l'Est), 27 (1906), No. 49, pp. 681-690, figs. 7.*)—Descriptions are given of *Orobancha minor*, an active parasite of clover, and attention is called to the necessity for careful cleaning of seed and the use of manures and fertilizers to prevent the spread of the parasite.

Eelworms, W. E. COLLINGE (*Univ. Birmingham, Dept. Econ. Zool. Circ. 1, pp. 4.*)—Brief accounts of the root knot eelworm (*Heterodera radicola*), which is exceedingly common and injurious to tomatoes, cucumbers, and other garden

crops, and the stem eelworm (*Tylenchus derastatrix*), which is reported as having been observed on numerous field crops and nursery stock. Notes on the life history of the different nematodes are given and preventive and remedial measures suggested for their control.

Experiments with tomato blight, H. B. ORR (*Northwest Hort.*, 20 (1907), No. 1, pp. 3, 4).—An account is given of experiments carried on by the author which seem to indicate that the severity of attacks of tomato blight is increased in proportion to the potash content of the fertilizers applied to the crops.

Cranberry diseases, C. L. SHEAR (*George Washington Univ. Bul.*, 5 (1906), No. 4, pp. 75-78).—An abstract of a thesis presented to the faculty of graduate studies of the university by the author, in which an account is given of cranberry diseases and experiments for their control.

The diseases described are the blast and scald caused by *Guignardia* sp., an anthracnose due to a species of *Gleocosporium*, and a rot which is attributed to an undescribed genus of fungus, to which the name *Acanthorhynchus* is given.

For the control of these diseases the author states that experiments have shown that Bordeaux mixture is the most effective fungicide. Experiments carried on in 1904 showed that the percentage of disease could be very materially reduced by spraying, and in 1905, under more favorable conditions, plats which received 5 applications of the fungicide yielded only 6 per cent of rotten fruit, as compared with more than 91 per cent on unsprayed plats.

A popular bulletin on these diseases has been noted previously (E. S. R., 17, p. 51).

The bacterial disease of ginger, Y. UYEDA (*Centbl. Bakt. [etc.]*, 2, Abt., 17 (1906), No. 11-13, pp. 383, 384, figs. 2).—A brief note is given on a bacterial disease of *Zingiber officinale*, which has been under observation for about 3 years in Japan.

The organism has been isolated, and inoculation experiments show that it is capable of causing the disease. A study of the organism has shown that it is probably a new species closely resembling *Bacillus omnivorus*.

A further contribution to the infectious chlorosis of mallows, E. BAUR (*Ber. Deut. Bot. Gesell.*, 24 (1906), No. 8, pp. 416-428).—In continuation of a previous paper (E. S. R., 18, p. 453) the author gives additional accounts of infectious chlorosis of a number of species of malvaceous plants. An immune strain of *Abutilon striatum* is described, and an account is given of the immunity of *Lavatera arborea*. The effect of light on the formation of virns of chlorosis in the leaves is discussed, after which the author describes experiments on the transmission of chlorosis by seed and also reports the occurrence of chlorosis on plants of other genera, particularly *Cornus*, *Ligustrum*, and *Laburnum*.

Soil treatment for the forcing house, A. D. SELBY (*Ohio Sta. Circ.*, 57, pp. 7, figs. 2).—An account of investigations for the control of rosette (*Rhizoctonia* sp.) in lettuce and tomatoes and of nematodes in crops grown under glass.

Experiments have been carried on for 3 years in testing soil sterilization with steam and formalin, and the author has found that for the destruction of fungi in the soil the formalin treatment and the steam treatment appear to be of about equal efficiency. In the case of nematodes, steaming appears to be the only effective treatment, particularly for the destruction of the encysted forms of nematodes. Directions are given for the treatment of soil with formalin and steam, and the comparative advantages and disadvantages of each are pointed out.

Some causes contributing to the black rot of apples due to *Sclerotinia fructigena*, E. MOLZ (*Centbl. Bakt. [etc.]*, 2, Abt., 17 (1906), No. 5-7, pp. 175-

188, pls. 2, figs. 5).—A study is reported of the disease of apples called black rot that is due to the fungus *Sclerotinia fructigena*. Apples affected by this form of the disease are black and shiny and are often reduced to mummy fruits of unusual appearance. The shining black color of the apple is confined to the skin, the flesh below being the usual brown color characteristic of *Monilia* diseases.

The author cultivated the fungus on apples, pears, apple pomace, gelatin, etc., and describes the growth obtained. It was found that light and temperature were important factors in determining the development of the fungus. The character of the substratum on which the fungus grew was also an influencing factor, the skin of the apple appearing to retard the fructification to a considerable degree. In all the apples inoculated with cultures of the fungus the black rot developed after a time, although the fungus remained sterile. Low temperatures and deficiency of light were also found to induce sterility.

Melanose, Cladosporium, and Septosporium, P. MARSAIS (*Rev. Vit.*, 26 (1906), No. 677, pp. 621-623, pl. 1).—Brief notes are given on diseases of grapes caused by *Septoria ampelina*, *Cladosporium viticolum*, and *Septosporium fockelii*. These diseases ordinarily make their appearance so late in the growth of the vine that they occasion but little injury, but when these fungi attack the young leaves the use of fungicides, particularly those containing copper, is recommended.

Notes on the disease of grapes known as roncet, S. ERCOLE (*Bol. Uffice. Min. Agr., Indus. e Com.* [Rome], 6 (1906), No. 4, pp. 373-381, figs. 3).—The author reviews the various hypotheses regarding the cause of this disease, not arriving at any definite conclusion concerning them. Certain stocks seem quite resistant to roncet, and the author recommends their use in the vineyard. The most resistant stocks are American varieties or some of their hybrids, and by planting these and following more careful cultural methods, it is claimed that losses due to the disease may be greatly lessened.

Notes on folletage of the grape, L. RAVAZ (*Prog. Agr. et Vit.* (Ed. VEst), 27 (1906), No. 49, pp. 690-692).—In a note upon the occurrence of this disease in Asiatic Turkey the author calls attention to the probability that it is due to a species of *Polyporus*, which seems to be *P. igniarius*. While the evidence seems clear that the disease is due to this fungus, it has not yet been demonstrated experimentally.

The American gooseberry mildew, E. S. SALMON (*Jour. Roy. Hort. Soc.* [London], 31 (1906), pp. 128-137, map 1).—The author traces the spread of the American gooseberry mildew (*Sphaerotheca mors-ura*) throughout Europe and suggests the need of legislation to combat its further dissemination.

The means employed to combat the American gooseberry mildew in Sweden, J. ERIKSSON (*Jour. Roy. Hort. Soc.* [London], 31 (1906), pp. 138-141).—Attention is called to the destructive nature of the gooseberry mildew (*Sphaerotheca mors-ura*) on European varieties of gooseberries, and means that have been employed in Sweden for combating the disease are described. These include inspection of nurseries, the destruction of badly diseased plants, cutting out of infected portions of plants, and spraying with potassium sulphid.

Investigations on the bacteriosis of figs, L. PETRI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5, ser., 15 (1906), II, No. 10, pp. 644-651, figs. 2).—An account is given of a bacterial disease of fig trees which was formerly reported by F. Cavara as due to *Bacterium ficis*.

The author in the study reported isolated the organism, cultivated it in various media, and successfully produced the disease through inoculation experiments. The cultural characteristics of the organism are described at

some length, and following a system of classification it is referred to *Ascobacterium tulcum*.

From the descriptions of several bacterial diseases of olives, oleanders, etc., and parallel cultures of the organisms causing them, the author is led to believe that they are all due to the species of bacterium mentioned above.

A disease of coffee in Peru, L. HECQ (*Bol. Min. Fomento [Peru]*, 4 (1906), No. 9, pp. 39-39, pls. 2, fig. 1).—An account is given of a disease of coffee due to *Stilbella florida*. This fungus is said to be causing considerable injury in the coffee plantations of Peru, and suggestions are given for its prevention. These include the destruction of infected plants, spraying with Bordeaux mixture, clean cultivation, etc.

A disease of hazelnuts, H. C. SCHELLENBERG (*Ber. Deut. Bot. Gesell.*, 24 (1906), No. 9, pp. 595-511, pl. 1).—A description is given of a disease of the hazelnut in which the male catkins are attacked by a species of *Sclerotinia*. The effect produced upon the host plant is described and comparisons made with the disease caused by *Ciboria bolavis*. The author claims that the fungi are quite distinct, and as the one causing the disease in question has not been technically characterized, he proposes the name *Sclerotinia corylli* n. sp. for it.

A fungus disease of the cherry laurel, E. S. SALMON (*Jour. Roy. Hort. Soc. [London]*, 31 (1906), pp. 142-146, fig. 1).—An account of the attack of the rose mildew (*Sphaerotheca pannosa*) on the cherry laurel. This fungus, which is common on species of the genus *Rosa*, is said to occur only sparingly on other plants, but has been reported as attacking the peach, apricot, almond, and cherry laurel. Spraying with potassium sulphid or the application of flowers of sulphur is recommended for combating the disease.

A disease of fir, L. MANGIN and P. HARIOT (*Compt. Rend. Acad. Sci. [Paris]*, 143 (1906), No. 22, pp. 840-842).—The attention of the authors was called during the summer of 1906 to a pronounced reddening of the leaves on a number of fir trees in the Jura region. The leaves had assumed a bright orange red color, which was in marked contrast with the dark green of the other foliage. The diseased leaves seemed to be more or less altered and in some cases the trees were badly affected.

An examination of the leaves showed the presence of a number of fungi, among them *Rhizospora abietis* n. g., *Macrophoma abietis* n. sp., *Cytospora pinastri*, and *Menoidea abietis* n. g. These different fungi which seem to be more or less associated with the disease are technically described and their probable relationships pointed out.

It is hoped by experimental studies to demonstrate the true cause of the disease, and inoculation experiments have already been begun with that end in view.

On the parasitism of *Merulius lacrymans*, O. APPEL (*Arb. K. Biol. Anst. Land u. Forstw.*, 5 (1906), No. 4, pp. 204-206, figs. 2).—A brief account is given of experiments by which the author sought to infect young seedlings of fir and pine with the dry rot fungus *Merulius lacrymans*.

The young trees were placed in pots, severe wounds made in the stems, and the mycelium of the fungus introduced, after which the plants were kept for several weeks in the moist atmosphere of the greenhouse. While the fungus grew abundantly, there does not appear to be any evidence that the dry rot fungus is able to live parasitically on young living coniferous trees.

A strangling disease of young birches, R. LAUBERT (*Arb. K. Biol. Anst. Land u. Forstw.*, 5 (1906), No. 4, pp. 206-212, figs. 5).—In the summer of 1905 attention was called to a great number of dead and dying birch seedlings. This led to an investigation of the cause of the trouble, and the author sep-

arated the following fungi from the diseased material: *Coniothyrium betulae* n. sp., *Fusicoccum betulinum* n. sp., *Sporodesmium cavernarum* n. sp., and *Pestalozzi hartigii betulae* n. var. Technical descriptions are given of the different fungi.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

General biology, O. HERTWIG (*Allgemeine Biologie, Jena; Gustav Fischer, 1906, pp. XVI+649, figs. 371*).—This volume is a second and revised edition, with a change of title of the author's work on the cell and the tissues. The first edition, under the latter title, was published in two parts, while all the material is brought together in one volume in the new edition. The subject-matter has been extensively revised and brought up to date.

Rabbit destruction (*Jour. Dept. Agr. West. Aust., 14 (1906), No. 4, pp. 281-284*).—The value of rabbits for food is briefly discussed and notes are given on the great destruction caused by rabbits where they multiply too rapidly. It is proposed to introduce a carnivorous red ant from South Africa which is said to attack rabbits, particularly the young, and kill them within 24 hours after birth. An examination of the feeding habits of these ants is being made to determine whether it would be safe to introduce them.

The serpents of Pennsylvania, H. A. SURFACE (*Penn. Dept. Agr. Mo. Bul. Div. Zool., 4 (1906), No. 4-5, pp. 115-208, pls. 42, figs. 23*).—The snakes known to occur in Pennsylvania are described and notes are given on their distribution, relative abundance, and feeding habits.

The destruction of injurious mollusks, G. GÁNDARA (*Com. Par. Agr. [Mexico], Circ. 53, pp. 15, figs. 6*).—In combating injurious slugs and snails, the author recommends collection by hand and the use of various spraying devices distributing irritating and poisonous substances.

Variation in parthenogenetic insects, V. L. KELLOGG (*Science, n. ser., 24 (1906), No. 622, pp. 695-699*).—It is commonly accepted at least by one school of biologists that variation in living organisms is partly the result of the mixing of the different tendencies from the 2 parents. According to this theory organisms produced parthenogenetically should show less variation. A study of this matter in bees and plant lice showed the opposite condition to be true. Drones, which are known to be parthenogenetic in origin, showed a greater variation than worker bees. In a few instances parthenogenetic eggs were obtained from worker bees and the drones produced from these eggs showed a great amount of variation. Similarly the variation observed in plant lice produced parthenogenetically showed as great a range as in the case of mosquitoes and other insects in which amphimixis takes place.

Zoological studies in the sand regions of the Illinois and Mississippi River valleys, C. A. HART (*Bull. Ill. State Lab. Nat. Hist., 7 (1907), Art. 7, pt. 3, pp. 195-272, pls. 5*).—In the investigations upon which this article is based, particular attention was given to the geographical distribution of important species of insects in the sand-hill regions of the Illinois and Mississippi River valleys. Observations were made on Orthoptera Hemiptera, Coleoptera, Neuroptera, Lepidoptera, and other orders of insects as well as upon batrachians and reptiles. A brief bibliography of the subject is given.

Report of the economic zoologist, H. A. SURFACE (*Ann. Rpt. Penn. Dept. Agr., 11 (1905), pp. 129-144*).—The work of the year has consisted in the examination of specimens sent in for determination, the investigation of various outbreaks of injurious insects, giving lectures in various parts of the State, the inspection of nurseries and orchards, and making collections of insects. Lists are given of the licensed nurserymen and tree dealers in Pennsylvania.

Insect notes for 1906, EDITH M. PATCH (*Maine Sta. Bul.* 134, pp. 209-228, pls. 4).—The author presents notes on the present status of brown-tail moth, gypsy moth, potato insects, alder blight, larch case-bearer, apple maggot, codling moth, diamond-back moth, etc. The diamond-back moth is reported as having been unusually injurious in greenhouses.

Notes on some Fijian insects, F. MUIR (*Hawaiian Sugar Planters' Sta., Div. Ent. Bul.* 2, pp. 11, pl. 1).—It was found that in Fiji the common species of sugar cane leaf hopper is held in check by various parasites. About 85 per cent of the eggs are parasitized and the young and adult leaf hoppers are attacked by *Elenchus tenuicornis*. This species was introduced in Hawaii but did not attack the leaf hoppers there. The insect is described and notes are given on its habits. *Pipimeculus ritiensis* is also described as a new species.

Some injurious insects, EMMA M. SOCH and F. A. BARTLETT (*Hampton Leaflets, n. ser., 2* (1906), No. 12, pp. 31, figs. 30).—Brief descriptions are furnished of a number of the more important injurious insects and practical remedies for controlling these pests are suggested.

Horticultural insect enemies, D. L. VAN DINE (*Hawaii, Forester and Agr.* 3 (1906), No. 11, pp. 341-350).—Brief notes are given on the anatomy of insects, the usual methods of controlling them by insecticides, orchard sanitation, natural enemies, and quarantine. A list is presented of the more injurious horticultural insects in Hawaii.

Some of the Coccinellidæ, G. W. DIMMOCK (*Informe An. Estac. Cent. Agron. Cuba, 1*, (1904-5), pp. 287-392).—An elaborate discussion is given of the anatomy, metamorphosis, and life history of the Coccinellidæ known to occur in Cuba. Detailed descriptions are given of species, with notes on their habits and with an analytical table to assist in identifying the species. A bibliography relating to the subject is appended to the article.

Notes on certain cranberry-bog insects, H. J. FRANKLIN (*Ent. News*, 18 (1907), No. 1, pp. 17-20).—A study was made of the insects on cranberry bogs in the region of Cape Cod in the season of 1906. Brief descriptive and economic notes are given of *Cymatophora sulphurea*, *Gleba sericea*, etc.

The important forest insects, G. GRÖNBERG (*Skogsrårdsför. Folkskr., No. 7*, pp. 32, figs. 37).—The author presents a general account of the habits, life history, and means of combating various species of *Melolontha*, *Hylobius*, *Pissodes*, *Scolytus*, *Tomicus*, *Bombyx*, *Psilura*, etc. Considerable attention is given to methods of fighting the nun moth in large forests.

The Hessian fly, H. A. GOSSARD and J. S. HOUSER (*Ohio Sta. Bul.* 177, pp. 39, pl. 1, figs. 3).—For several years the station has made observations on the habits of the Hessian fly and practical means of combating this pest. The insect is described in its various stages and notes are given on its life history and food plants.

Observations extending over a period of 3 years give little support to the idea of immune varieties of wheat. The strength of the straw, however, is an important factor. Stiff vigorous straw will stand up under infestation with one and sometimes more of the insects. It appears that wheat well fertilized, particularly with phosphatic manures, will produce a heavy strong straw which will resist the attacks of the Hessian fly much better than wheat which has been excessively fertilized with nitrogen.

In combating the Hessian fly with direct remedies, the best results are obtained from burning the stubble. This should be done before the flies have emerged from the stubble or before the first of September. In the southern parts of the State the stubble should be burned by the middle of August. Where burning is not practicable good results will follow fall plowing in which the stubble is turned under to a depth of several inches.

The authors recommend as a general programme for controlling the Hessian fly that seed should be selected from a crop showing large or medium straw with excellent stooling qualities. The ground should be thoroughly cultivated and the seed sown not too late, since the damage can sometimes be overcome more successfully by early sowing than it can be avoided by late sowing.

The locust plague, M. T. PIZARRO (*Com. Par. Agr. [Mexico], Circ. 52, pp. 11, figs. 11*).—Arsenical sprays have proved quite efficient in controlling injurious locusts in Mexico. Mention is also made of locust fungus, the uses of various mechanical devices, and the benefits derived from the presence of insectivorous birds.

The locust invasion, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope, 29 (1906), No. 5, pp. 596-600*).—An outline is given of the means by which the local government proposes to aid in the extermination of locusts. The government furnishes men to organize campaigns against the locust and also assists infested districts by furnishing spraying materials.

The control of locusts, F. LAHILLE (*Bol. Min. Agr. [Buenos Ayres], 6 (1906), No. 1-2-3, pp. 69-109, pls. 3, figs. 2*).—The life history and habits of locusts are described with special reference to suitable methods for controlling these insects. Considerable success has been had from the use of a poisoned bait containing sugar and white arsenic. A quite thorough test was made of *Empusa acridii* which was distributed over large areas infested with locusts. Other fungi were also tested with fairly satisfactory results.

The author found that a mite (*Podapolipus bertesci*) renders some assistance in controlling locusts by living as a parasite upon them. This mite is described in all its stages.

The rice grasshopper, J. B. KNIGHT and R. M. DIXON (*Dept. Agr. Bombay Bul. 27, pp. 4, figs. 3*).—*Hicroglyphus furcifer* attacks rice, sugar cane, sorghum, corn, and various cultivated as well as wild grasses. The pest is described in its various stages and notes are given on its natural enemies which assist somewhat in its control. In combating the insect, infested fields should be thoroughly plowed in January and February. Good results are also reported from the use of sweeping nets in catching the young insects.

The San José or Chinese scale, C. L. MARLATT (*U. S. Dept. Agr., Bur. Ent. Bul. 62, pp. 89, pls. 9, figs. 12*).—The Bureau has previously published general accounts of the San José scale in Bulletin 3 (E. S. R., 8, pp. 500, 501) and in Bulletin 12 (E. S. R., 10, pp. 370, 371). The present bulletin is a thorough revision of previous publications on San José scale by the Bureau with additional notes regarding the travels of the author through China and other Asiatic countries and the evidence in favor of considering China as the original home of this scale.

The San José scale in Alabama, F. H. CARDOZA (*Alabama Tuskegee Sta. Bul. 9, pp. 10, pl. 1*).—This bulletin contains practical information for the use of colored farmers in Alabama. It is recommended that badly infested trees be sprayed soon after the wood has matured in the fall and again in the spring before the buds open. The best results were obtained from the use of a line-sulphur-salt solution made in the proportion 25:16:10:50.

Commercial miscible oils for treatment of the San José scale, P. J. PARROTT, H. E. HODGKISS, and F. A. SHRINE (*New York State Sta. Bul. 281, pp. 261-270*).—Proprietary miscible oils were tested in spraying 1,368 trees in solutions containing 1 part oil to from 10 to 25 parts of water. The weaker solutions failed to give uniform results, although the fruit was somewhat spotted by the treatment. When used at the rate of 1 part of oil to 10 or 15 parts of water the scale insects were more completely destroyed, but the mixtures were not

quite as effective as lime-sulphur wash. The authors recommend that miscible oils should not be used in weaker solutions than 1:10 or 15 parts of water.

Miscible oils have the advantage of being convenient to prepare and apply and are suitable for use in small orchards and individual trees in gardens. They are, however, altogether too expensive for use on a commercial scale. In some instances, the miscible oils give such unsatisfactory results that the fruit grower must make additional summer and fall applications in order to eradicate the scale.

Miscible oil sprays, F. H. HALL (*New York State Sta. Bul.* 281, *pop. ed.*, pp. 7, *fig. 1*).—A brief summary of Bulletin 281 of this station noted above.

Patent washes for San José scale, C. E. CRAIG (*Va. Crop Pest Com. Circ.* 2, *n. ser.*, pp. 11).—A number of proprietary lime-sulphur mixtures and miscible oils were tested in comparison with lime-sulphur wash. The last-named insecticide proved to be the cheapest and most effective for orchard work. Some of the washes are convenient for use in a small home garden, but are too expensive as compared with lime-sulphur wash for general orchard work.

Lime-sulphur wash studies, 1904-1906, J. L. PHILLIPS (*Va. Crop Pest Com. Circ.* 1, *n. ser.*, pp. 23).—A chemical study was made of various lime-sulphur mixtures prepared in different ways or from different formulas.

The author concludes as a result of this study that practically all of the sulphur is dissolved by vigorous cooking for 40 minutes and that the yellow color of the wash is due to the mechanical mixture of the liquid and sediment. If cooking be prolonged a somewhat larger per cent of lime combines with the sulphur, but this is of little practical importance. If the wash is cooked in concentrated form some sulphur is lost by volatilization. The presence of magnesia or other impurities in the lime may also cause a considerable loss of sulphur.

The codling moth, C. BÖRNER (*Deut. Landw. Presse.* 3½ (1907), No. 3, pp. 17, 18, *figs. 6*).—In Germany the codling moth goes through only one generation per year. A number of natural enemies of the pest are known, but spraying and banding of trees are considered necessary.

A new cabbage-eating larva, G. H. CARPENTER (*Jour. Econ. Biol.*, 1 (1906), No. 4, pp. 152-156, *pl. 1, fig. 1*).—The common beetle *Psylliodes chrysocephala* was observed boring in young cabbage plants in the larval condition. The infested plants were destroyed, and in this way much injury was done, since a considerable percentage of the plants was attacked. The habit of feeding upon cabbage plants appears to be newly acquired.

A new enemy of the raspberry, P. MARCIAL and J. VERCIER (*Bul. Mens. Off. Renseign. Agr. [Paris]*, 5 (1906), No. 12, pp. 1494-1499, *figs. 4*).—The authors report serious injury to raspberries from the attacks of *Agrilus chrysoederes rubicola*. Infested canes show fusiform swellings resembling galls at various points. The larvae of the beetles live in these swellings. In combating this pest it is recommended that all infested canes should be cut and destroyed in winter and that the raspberry patch should again be examined for the presence of the pest in May.

The life history of a cochlidian moth (Adoneta bicaudata), H. G. DYAR (*Biological Studies by the Pupils of William Thompson Sedgwick. Boston: June, 1906, pp. 11-19, pl. 1*).—The author has given considerable attention to the life history of species of this group and describes *Adoneta bicaudata* in its various stages, together with notes on its peculiar life history.

A winter spraying of fruit trees, W. E. COLLINGE (*Univ. Birmingham, Dept. Econ. Zool. Circ.* 2, pp. 2).—In experiments in controlling the plant lice on apple

trees and also a number of other related insect pests good results were had from the use of a mixture containing 2 lbs. of caustic soda, 0.5 lbs. soft soap, and 5 pts. of kerosene in 10 gal. of water.

Tobacco as an insecticide, J. R. INDA (*Com. Par. Agr. [Mexico], Circ. 44*, pp. 4, fig. 1).—The general insecticide value of tobacco is discussed, with mention of specific instances in which it is particularly adapted for use.

An apparatus for testing the value of fumigating agents, A. I. KENDALL (*Biological Studies by the Pupils of William Thompson Sedgwick, Boston; June, 1906*, pp. 313-320, figs. 5).—A detailed description is given of an apparatus for testing the efficiency of various fumigating substances in the destruction of mosquitoes and other household insects. The author reaches the conclusion that the results obtained from a given amount of fumigating substances per unit of space in a small box may be safely applied to large rooms, since in his experience the effect of fumigating substances is more pronounced in large spaces than in small laboratory apparatus. It also became apparent during the author's investigation that the more rapidly the fumigating substances were volatilized or set free the more efficient their action.

White ants, J. DESNEUX (*Informe An. Estac. Cent. Agron. Cuba, 1 (1904-5)*, pp. 393-407, pl. 1, figs. 9).—The different forms of individuals observed in colonies of white ants are described and notes are given on the nest building of these insects.

On the life history of *Stomoxys calcitrans*, R. NEWSTEAD (*Jour. Econ. Biol., 1 (1906)*, No. 4, pp. 157-166, pl. 1).—While the favorite habitat of this fly is found in barnyards and stables, the author failed to find a larval condition in the manure in such locations as was naturally to be expected. After considerable search, however, the larvae were found in decaying grass cuttings which had been piled up around cucumber beds. The insect is described in its various stages and brief notes are given on its habits. The author estimates the time required for a complete cycle from one generation to another at from 42 to 78 days.

Some Scottish Ixodidæ (ticks), W. EVANS (*Ann. Scot. Nat. Hist., 1907*, No. 61, pp. 34-37).—Brief mention is made of the appearance and habits of *Ixodes ricinus*, *I. herzogous*, *I. putus*, etc.

Improvement of honeybees, F. BENTON (*Ann. Rpt. Penn. Dept. Agr., 11 (1905)*, pp. 705-712).—The author describes briefly the chief characteristics of the common races of bees with particular reference to their relative merits and demerits. Advice is also given regarding the selection of queens for breeding purposes.

Swarming of bees, H. VON BUTTEL-REEPEN (*Ztschr. Wiss. Insektenbiol., 2 (1906)*, No. 11, pp. 359-361).—A controversial article dealing with the cause of swarming in bees.

Foul brood and other diseases of bees, N. E. FRANCE (*Ann. Rpt. Penn. Dept. Agr., 11 (1905)*, pp. 691-694, pls. 2).—This disease is most frequently transmitted to uninfested localities by selling infested bees, combs or bee supplies, by shipping queens from infested apiaries or through the agency of robber bees. The symptoms of the disease are briefly described and a suitable treatment is outlined.

The laws in force against injurious insects and foul brood in the United States, L. O. HOWARD and A. F. BURGESS (*U. S. Dept. Agr., Bur. Ent. Bul. 61*, pp. 222).—This bulletin contains copies of the laws in force in various States for the control of injurious insects and foul brood. The laws are arranged alphabetically according to States and contain references in relation to plant

diseases as well as injurious insects. A brief summary was also given of the work accomplished by the American Association of Horticultural Inspectors at its various meetings.

FOODS—HUMAN NUTRITION.

The elements of the science of nutrition, G. LUSK (*Philadelphia and London: W. B. Saunders Co., 1906, pp. 326, pl. 1, figs. 11*).—It has been the author's purpose to review the scientific data upon which rests the knowledge of nutrition in both health and disease with a view to more fully meeting the interest in the subject which at the present time is manifested by students of dietetics, physicians, and others.

Clear and concise summaries are given of the theories of nutrition. Such subjects as the regulation of temperature, the influence of proteid food, the specific dynamic action of the foodstuffs, the influence of the ingestion of fat and carbohydrate, the influence of mechanical work on metabolism, a normal diet, the food requirement during the period of growth, purin metabolism, general theories of metabolism, and metabolism in different diseases are among the topics discussed.

Throughout the volume citations are made from the literature of the subjects treated and the volume as a whole presents a concise and valuable summary of information, much of which has not been readily accessible to the student. The volume also gives a reasonably complete summary of the views which are at present held regarding nutrition in health and disease and full indexes add to its value.

Human foods, J. ALQUIER (*Rev. Soc. Sci. Hyg. Aliment., 3 (1906), No. 1, pl. 1, pp. 68, figs. 4; pt. 2, pp. 6+tables XIV*).—The author has prepared an extended compilation of analyses of animal and vegetable foods. The recorded data show maximum, minimum, and average values and the proportions of total and digestible nutrients. Tables are also given showing the amount of various food materials which are equivalent to 100 lbs. of a given material taken as a standard. In the introductory section, methods of cutting meat and other questions are discussed and the system of tabulating results is explained.

Human food, J. ALQUIER (*Les Aliments de l'Homme, Paris: Masson & Co., 1906, pts. 1, pp. 68, figs. 4; 2, pp. 6+tables XIV*).—A reprint of the above in book form.

Food analyses, V, J. T. WILLARD (*Bul. Kans. Bd. Health, 2 (1906), No. 12, pp. 300-307*).—The analyses reported include milk, ice cream, a substance sold for use in thickening ice cream, butter, water, and ice.

Of the 34 samples of ice cream examined only one was found to contain borax. Formaldehyde was not found. Four of the samples contained starch. The butter-fat content varied from 2.7 to 18.4 per cent, being 9.66 per cent on an average. If 12 per cent fat be adopted for a standard, as suggested by the author, over half of the samples would fall below the standard.

"It would seem that the manufacturer furnishing a high grade of ice cream, which is really nutritious and contains a good per cent of butter-fat, should be protected against the vendors who put upon the market an article of very inferior quality, containing no more butter-fat than a good quality of milk. At any rate the customer should pay less for the cheaper cream.

"There are quite a number of products on the market which are used to thicken cream, so that from a very low grade of cream a product may be obtained which somewhat resembles that from a high grade of cream. These

substances, while they may not be injurious, are simply thickening material, and serve to cheapen the product."

The substance sold to thicken ice cream was a white powder with a slightly sweet taste and used in the proportion of an ounce to 10 gallons of ice cream. It consisted essentially of gum tragacanth, which has the property of swelling to a large bulk when mixed with water. The powder contained 1.77 per cent ash, largely in the form of lime.

Bleaching of flour, E. F. LADD and R. E. STALLINGS (*North Dakota Sta. Bul.* 72, pp. 219-235, fig. 1).—Samples of flour bleached under known conditions were examined and compared with unbleached flours, the bleaching being accomplished by the ordinary commercial process employing oxides of nitrogen.

In testing for the presence of oxides of nitrogen a weighed amount of flour or bread was placed in a flask of distilled water and shaken at intervals for 30 minutes. After filtering, a drop of concentrated hydrochloric acid, 1 cc. of sulphanic acid, and 1 cc. of naphthylamin hydrochlorid were added, the mixture shaken, covered, and allowed to stand for 30 minutes. A known amount of a standard solution of sodium nitrate was treated in the same manner and the solutions compared with the standard in the colorimeter. In all cases it was found that the nitrous oxids remained in the flour after bleaching and the oxid or its salts were also found in bread baked from bleached flour. Baking tests showed that bleached flour gave smaller loaves than unbleached flour. The quality of the wheat gluten was injured by bleaching.

In general, the authors' results were regarded as unfavorable to bleaching. The principal conclusions were in effect as follows:

Bleaching is not an improved milling process but is the introduction of chemical agents for the purpose of treating the flour which is analogous to the bleaching of fruit and other food products. There is employed in the process of bleaching a chemical agent which is physiologically quite active, namely, nitrous oxid.

Bleaching permits of using low-grade flours in place of patents. Low-grade flours produced from well-cleaned wheat can be successfully bleached to resemble high grades or patents.

"The processes for bleaching have been devised for bleaching and 'improving' the color of inferior flours. The manufacturers of these processes openly claim that they (the millers) can increase the percentage amount of patent produced. From our tests it would seem that this could be done without the purchaser becoming any the wiser because the clear grade of flour was susceptible of being 'improved' as well as the patents. . . .

"The claim is made that nitrous acid will form in flour from the air. Our experiments do not indicate this to be the case."

Indian corn as food for man, L. H. MERRILL (*Maine Sta. Bul.* 131, pp. 133-145).—The digestibility of corn meal prepared in different ways and of hominy was studied. In some cases the corn products were eaten with sugar, milk, and sometimes butter, and in others the diet was more varied, though the corn product was its principal constituent. Wheat bread was also studied for purposes of comparison. In every case the digestion experiments were made with healthy subjects. The following table summarizes the results obtained for the total diet and calculated for the corn products alone:

Coefficients of digestibility of a ration containing corn products and corn products alone.

Kind of food,	Total diet,				Corn products,			
	Total protein.	Protein corrected for metabolic products.	Carbohydrates.	Energy.	Total protein.	Protein corrected for metabolic products.	Carbohydrates.	Energy.
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Hominy in simple diet.....	83.6	89.2	99.0	96.4	74.5	84.3	98.2	94.4
Hominy in mixed diet.....	88.9	93.6	98.8	96.3				
Hasty pudding in simple diet...	82.3	89.2	99.0	95.9	73.2	83.9	98.3	93.1
Hasty pudding in mixed diet...	89.0	94.0	98.9	96.9				
Johnny-cake in simple diet.....	89.6	94.9	98.7	93.8	86.3	93.2	98.9	93.5
Johnny-cake in mixed diet.....	90.1	94.8	99.3	93.9				
Brown bread in simple diet.....	87.4	94.7	98.7	93.5	83.0	92.8	98.6	93.4
Brown bread in mixed diet.....	89.5	95.5	99.4	92.9				
Hoe-cake in simple diet.....	87.0	93.9	98.7	93.7	77.1	88.9	98.6	93.8
Hoe-cake with sirup.....	84.4	92.6	99.2	95.5	78.8	90.0	98.7	94.0
Hoe-cake in mixed diet.....	90.0	94.6	98.8	92.6				
White bread in simple diet.....	89.2	94.0	98.9	94.0	85.6	89.8	98.9	94.0
White bread in mixed diet.....	92.6	96.1	99.0	98.2				

Considering the diet as a whole, the author notes that, "in every case but one, the protein of the mixed diet was more completely digested than that of the simple diet. The low digestibility of a simple diet has been often noted in previous experiments.

"With a simple diet the protein of the johnny-cake and the brown bread seems to have been slightly more digestible than that of the white bread. With the mixed diet, the white bread shows a digestibility distinctly greater than that of the corn breads.

"The use of sirup with the hoe-cake to a slight degree depressed the digestibility of the protein. This is in accordance with other experiments in which the digestibility of the protein apparently varied with the ratio existing between the protein and the other nutrients."

As pointed out by the author, the calculated values for the digestibility of the corn products alone indicate that they "are either considerably less digestible than the other foods with which they were eaten, or they themselves become more digestible when eaten with other foods. Similar results obtained with other experiments in which certain foods were eaten both singly and with a mixed diet indicate that the second conclusion is the correct one."

The corn and wheat breads used in the experiments were analyzed.

A dietary study of laborers and clerks in Paris, L. LANDOUZY and H. and M. LABBÉ (*Enquête sur l'Alimentation d'Une Centaine d'Ouvriers et d'Employés Parisiens*. Paris: Masson & Co., 1906, pp. 72; rev. in *Rev. Gén. Sci.*, 17 (1906), No. 24, p. 1083).—Data were collected regarding the character of the food consumed by laborers and clerks in Paris, the proportion of income expended for different foods, and related topics.

According to the authors, the diet was deficient and the expenditure for condiments and other materials of low food value was high. Suggestions are made for securing adequate rations for the same expenditures.

A new method of testing the functions of the digestive apparatus, M. ERNORX (*Med. Rev.* [N. Y.], 69 (1906), No. 6, pp. 205-209, figs. 3).—The author attached small portions of different foods to porcelain beads, either by drawing them through the aperture in the bead or by tying the food to the beads. By using different colored beads it was possible to identify the materials after they had passed through the digestive tract.

In some of the tests the beads with the food material attached were inclosed in gauze so that the food substances could not come in direct contact with the walls of the digestive tract. In tests designed to study the effects of gastric digestion beads were attached to a silk thread and were withdrawn from the stomach after a suitable interval.

Experiments with healthy persons showed, according to the author, that both catgut and fish bones were digested in the stomach, whereas boiled or raw meat (beef), raw chicken skin, and both raw and boiled potatoes do not dissolve altogether in this organ. Fish bone was selected for these experiments as its solution in the digestive tract is positive indication of the presence of gastric juice. Catgut was used for the same purpose but is not as satisfactory.

In the case of meat a swelling and lessening of the fibers was noted in the stomach. Raw muscle fiber and chicken skin disappeared in the intestines. Tendons, however, remained undigested. Raw potatoes varied, sometimes digesting entirely and sometimes passing through the body unchanged. Boiled potato, generally speaking, was apparently digested in the bowel, while the skin of potato, either raw or boiled, was always excreted unchanged. Wax, paraffin, and fats with a high melting point, such as stearic acid, etc., were not absorbed in the intestine, but suet and mutton fat, which melt at 50° C., were digested in the bowel. Other experiments made with mutton fat showed that it remained unchanged in the stomach.

To determine whether the disappearance of mutton fat in the intestines was a chemical or mechanical process produced by the epithelium of the intestine, beads containing mutton fat and surrounded by gauze were swallowed. All the mutton fat in the beads disappeared which, according to the author, shows that chemical processes play the principal part in the absorption of mutton fat. Thyms gland and potato were taken in a similar way and it appeared that the gauze envelope did not hinder digestion.

The results obtained with normal subjects, in the author's opinion, show that the method can be employed for testing digestion in disease and a number of experiments made under pathological conditions are reported.

The acceleration of the action of the pancreatic juice by the salts of calcium, E. DELEZENNE (*Brit. Med. Jour.*, 1906, No. 2399, pp. 1785, 1786).—As pointed out by the author in a paper presented at the Toronto meeting of the British Medical Association, the pancreatic juice obtained in its inactive form from the pancreatic duct either by means of a permanent fistula or by the aid of intravenous injections of secretin acquires a very powerful proteolytic activity when mixed with a suitable quantity of a soluble calcium salt and incubated for several hours.

"The action of the salts of lime must be considered a specific one. The salts of other metals of the same series (barium, strontium, magnesium) have little or no effect. Any slow action they may appear to possess may be explained by the presence in them, or in the pancreatic juice itself, of traces of soluble calcium salts."

Chemical processes in the animal body, R. O. HERZOG (*Chemisches Geschehen im Organismus*, Heidelberg: Carl Rössler, 1905, pp. 62).—The possibilities are discussed of applying to the important ferment reactions of the living body the theories of chemical equilibrium and velocity of reaction. Although the results as yet obtained are not altogether satisfactory, the author believes that a mathematical treatment of the problem is possible. In a special case, dog pepsin, a formula is proposed for the rate of secretion of the enzyme.

Chemical studies on growth, L. B. MENDEL (*Brit. Med. Jour.*, 1906, No. 2399, pp. 1787, 1788).—A paper was presented at the meeting of the British Medical Association at Toronto, 1906, which summarized the investigations of the author and his coworkers which have to do with the composition and the chemical changes which are characteristic of developing organisms and the equipment of such organisms for utilizing the nutritive materials presented to them.

The investigations of hens' and ducks' eggs after varying periods of incubation have furnished new evidence regarding the synthesis of purins in embryonic forms. The fresh egg is practically free from purins. The quantities of purins gradually increase during incubation until the young are fully hatched.

The specific purin compounds which especially are synthesized as a part of the newly-formed nucleoproteid constituents are guanin and adenin, traces only of hypoxanthin being obtained. . . . We have found that the liver tissue of the embryo (pig) has apparently not yet acquired the capacity of destroying uric acid to any considerable extent, if at all—in striking contrast with comparable material from adult animals. . . . One may conclude that the embryonic organs, such as the liver, are early equipped for the preliminary reactions in purin synthesis and degradation, in harmony with the extreme richness of the embryonic liver morphologically in nuclear materials.

“Nucleic acids are characterized by the presence of pentose groups, as well as purin complexes. The egg itself is practically free from furfural-yielding compounds. With the progress of incubation pentose groups are synthesized, as might be expected from the characteristic development of nuclear materials.”

The development of specific enzymes, the glycogen content of the embryo, and lipoids are also considered. In general, “analyses of the water-free and fat-free tissues of animals fed on diets of widely different character indicate the tendency of the tissues to maintain a constant chemical character.”

Metabolism experiments with organic and inorganic phosphorus, J. A. LÉCLERC and F. C. COOK (*Jour. Biol. Chem.*, 2 (1906), No. 3, pp. 203-216).—Studies were made with 2 rabbits and a dog in which inorganic phosphorus in the form of disodium phosphate and such organic phosphorus compounds as occur in wheat bran and in egg yolk were compared. In the authors' opinion the experiments point to the following conclusions:

The amount of nitrogen retained is generally lowered by the addition of inorganic phosphorus when fed with a normal food. The nitrogen balance is not necessarily negative.

In the case of food supplying little phosphorus, the addition of inorganic phosphorus decreases the digestibility of the nitrogen and the nitrogen and phosphorus balances are usually negative.

Organic phosphorus favors nitrogen metabolism and increases the nitrogen and phosphorus retention, especially in the case of the food supplying little phosphorus. Organic phosphorus, therefore, is more favorable to nitrogen and phosphorus retention than is inorganic phosphorus. The phosphorus of wheat bran appears to be a most valuable food constituent.

The nitrogen of bran was poorly assimilated. The loss of nitrogen during the periods in which bran was fed agree with earlier work, showing the low digestibility of bran nitrogen and corroborate the results obtained regarding the absorption of bran phosphorus.

The nitrogen and phosphorus balances do not run parallel in all cases; the general tendency is in that direction.

In no case was there any retention of the added phosphorus, whether fed in the organic or in the inorganic form, when given with a food containing a normal amount of phosphorus.

In no case was organic phosphorus found in the urine even when an extra amount of organic phosphorus was ingested.

The greater part of the phosphorus, whether organic or inorganic, was excreted through the kidneys.

Nitrogenous metabolism as affected by diet and by alkaline diuretics, H. D. HASKINS (*Jour. Biol. Chem.*, 2 (1906), No. 3, pp. 217-229).—The rations selected included a low diet made up of vegetable foods with a little milk and cream and considerable butter, a "standard" diet furnishing about 15 gm. of nitrogen and made up of vegetable foods and milk and eggs in considerable quantity, a "heavy" diet similar in character to the "standard" diet and furnishing 23 gm. of nitrogen, and a meat diet which contained about 390 gm. of very lean chopped beefsteak beside milk, butter, bread, and dates. One of the 3 men who served as subjects also followed a purin-free diet for several days. With this subject no account was kept of the fuel value of this ration, but the author considers that his diets were deficient in energy. With the other 2 subjects the fuel value of the diet was calculated to be about 3,000 calories.

Neither sodium citrate nor sodium bicarbonate, when added to the ration, influenced the total nitrogen excretion. They also failed to cause diuresis.

"The sudden change to a low diet caused in each experiment an initial fall in body weight, but this was quickly recovered from in both cases where the fuel value was sufficient. The weight of these 2 men increased slightly on the heavier diet." The subject whose diet was deficient in energy lost steadily throughout the experiment until the meat diet was begun.

The recorded data "show that nitrogenous equilibrium is quickly secured if the nitrogen intake does not drop below 5 gm., as others have also observed. The nitrogen excretion remains fairly constant at 5 to 6 gm. even when the food nitrogen drops below that amount. . . . On the standard and on the meat diet an approximate nitrogenous equilibrium was readily obtained; on the heavy diet, however, equilibrium was not secured, 16 gm. being the maximum nitrogen excretion."

In these experiments the alkalis studied decreased the ammonia excretions very markedly under all conditions of diet, the ammonia being usually reduced to one-third of the amount normally excreted. At the same time the urea excretion was increased, the amount corresponding roughly to the decrease in the ammonia excretion.

The metabolism of creatin and creatinin, O. FOLIN (*Brit. Med. Jour.*, 1906, No. 2399, p. 1787).—The conclusions drawn from the data presented at the meeting of the British Medical Association at Toronto, 1906, follow:

"There is no experimental evidence showing that creatin is the immediate precursor of the creatinin appearing in the urine.

"Biologically there seems to be a fundamental difference between creatinin and creatin.

"In the author's opinion it is not yet clear whether creatin is a waste product or a food."

Carbohydrate metabolism, F. W. PAVY (*London: J. & A. Churchill; Philadelphia: P. Blakiston's Son & Co.*, 1906, pp. XII+138 pls. 8).—This volume contains a course of lectures given at the University of London in 1905 and is largely made up of the author's experiments and his deductions and conclusions from them. The subject is discussed from a physiological and a pathological standpoint.

Some properties of the albumens present in duck egg white, A. PANORMOW (*Zhur. Russ. Fiz. Khim. Obsch.*, 37 (1905), pp. 923-931; *abs. in Ztschr. Untersuch. Nahr. u. Genussmit.*, 12 (1906), No. 11, pp. 665, 666).—Two albumens,

anatin and anatinin, were identified in the white of duck egg and, according to the author, these are the only albumens present, the relative proportion being one part of anatin to two of anatinin.

Concerning dried fruit, R. STECHER (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 12 (1906), No. 11, pp. 645-652).—Analyses of a large number of samples of dried plums, prunes, pears, and apples are reported, the studies being undertaken with special reference to composition and the market and shipping qualities.

The acidity of fruits, W. F. SUTHERST (*Chem. News*, 92 (1905), No. 2393, p. 163; *abs. in Ztschr. Untersuch. Nahr. u. Genussmtl.*, 12 (1906), No. 11, p. 671).—The acid flavor of fruits is usually more noticeable after cooking and, according to the author, this is due to the fact that cooked fruit (gooseberries, currants, plums, etc.) usually contains the skin, which is commonly rejected if the fruit is eaten raw. The skin is more acid than the pulp. As was shown by analyses of gooseberries, the skin contained 2.66 per cent acid, expressed as tartaric acid, and the pulp 1.80 per cent.

To determine whether acid is formed when fruit is cooked, a mixture of nearly ripe gooseberries and water was boiled for about 30 minutes and then titrated with sodium-hydroxid solution. The boiled portion contained less acid than the raw. "due, no doubt, to the volatility of some of the acids."

As regards the effect of cooking on the kind and amount of sugar present, uncooked gooseberries were found to contain 1.16 per cent cane sugar and 5.84 per cent invert sugar. After boiling, no cane sugar was found, while the invert sugar amounted to 6.91 per cent. This indicates that "all the sugar undergoes inversion during cooking, the acid present bringing this about as in the usual process of hydrolysis."

Canned artichokes, P. CARLES (*Rcv. Internat. Falsif.*, 18 (1905), pp. 80, 81; *abs. in Ztschr. Untersuch. Nahr. u. Genussmtl.*, 12 (1906), No. 11, p. 673).—Artichoke buttons are the portion used for canning. They contain a large amount of oxydase which acts upon the tannin or other oxidizable material present and causes a brown discoloration. Short treatment with a cold 2 to 10 per cent sulphurous-acid solution before canning is recommended by the author to prevent discoloration. In addition to sulphurous acid citric acid and tartaric acid are used. After an hour in the acid the artichoke buttons are washed, seasoned, and processed.

Chuño, a frozen potato product from Bolivia, E. PAROW (*Ztschr. Spiritus-indus.*, 28 (1905), p. 405; *abs. in Ztschr. Untersuch. Nahr. u. Genussmtl.*, 12 (1906), No. 11, p. 672).—The potato product described is made by crushing frozen potatoes and removing the greater part of the moisture present by further exposure to cold and to the air. The resulting hard mass contains about 15 per cent water and may be kept for a considerable time. As shown by analyses, the material resembled German dried potatoes quite closely in composition.

Concerning spices, H. SPRINKMEYER and A. FÜRSTENBERG (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 12 (1906), No. 11, pp. 652-658).—The authors determined the water and ash constituents in a large number of samples of pepper, cinnamon, allspice, and cloves. The fact is recognized that in certain spices, for instance, pepper, there are great variations in the ash content, while in others, as allspice and cloves, the variations are small, yet the authors do not believe that such data are sufficient for judging of the quality of the goods.

Digestion experiments with chestnuts, L. H. MERRILL (*Maine Sta. Bul.* 131, pp. 146-148).—Two experiments are reported in which the digestibility of chestnut flour cooked as mush was studied with healthy men. Some bread, potatoes, and milk were eaten with the chestnut flour. The calculated digestibility of chestnut flour alone with one subject was, protein 41.6 per cent, fat 53.5 per cent.

carbohydrates 97.1 per cent, and the available energy 86.4 per cent. With the second subject, the coefficients of digestibility were, protein 69.5 per cent, fat 71.9 per cent, and carbohydrates 98.6 per cent, while the available energy was 92.2 per cent.

Marula nuts (*Transvaal Agr. Jour.*, 5 (1906), No. 17, pp. 136, 137).—An analysis of the kernel of the fruit of the marula tree (*Sclerocarya caffra*) is reported. The marula nut contains about 50 per cent of oil which it is believed might be used as a substitute for olive oil in cloth manufacture. The iodine value of the oil was found to be 74. Other constants were also determined.

ANIMAL PRODUCTION.

Foods and fodder plants, W. R. DUNSTAN (*Rpt. Imp. Inst. So. Kensington*, 1905, pp. 18–20).—Brief statements are made regarding the extent and character of the analytical and other work pertaining to foods and plants. Studies of Cape Colony oats were undertaken as it has been alleged that they are unsuitable as forage and produce a peculiar bone disease in animals fed with them. From a study of 4 typical samples the conclusion was reached that the oats were deficient in mineral constituents, which are important bone-forming materials, "and it is probably to this deficiency that the ill effects observed in horses fed with these oats are due."

In a study of the occurrence of hydrocyanic acid in feeding stuffs, large quantities were found in beans (*Phaseolus lunatus*) ground up and moistened with water. A number of cases of cattle poisoning have been reported which were due to feeding such Java beans.

Commercial feeding stuffs, T. I. MAIRS (*Pennsylvania Sta. Bul. 81*, pp. 15).—The characteristics of different commercial feeding stuffs are discussed and the methods of manufacture and preparation of a number of commercial by-products are briefly spoken of.

As regards alfalfa meal, a feeding stuff which has been recently placed on the market, the author states: "It is merely ground alfalfa hay. It is recommended by the makers as a substitute for bran. There seems to be no reason why it should be any more digestible than the hay from which it is made. It may possibly be less digestible than average hay on account of there being so great a temptation to grind the poorer grades of hay. It forms a part of many of the so-called dairy and stock feeds." Some of these commercial feeding stuffs contain molasses in addition to alfalfa meal.

As regards grinding in general, the author notes that it "adds comparatively little to the digestibility of the feed for healthy animals. It may even tend to detract from it, as the ground feed is more apt to be swallowed without chewing and mixing with the saliva. It is an expensive process, particularly where it is necessary to haul the grain some distance to the mill and pay from one-eighth to one-sixth toll. With corn at fifty cents per bushel one-eighth toll amounts to twelve and three-quarter cents per hundredweight, or \$2.55 per ton. . . . Some millers charge a flat rate of about \$2 per ton, varying with the kind of grain to be ground. This is usually more equitable and more economical. To this cost must be added the expense of hauling the grain to the mill and returning the feed. Where much grinding is to be done, it pays the farmer to own his mill."

A summary of data on the amount of total digestible nutrients furnished by the different feeding stuffs shows that under local conditions "corn-and-cob meal, buckwheat middlings, wheat middlings, and hominy chop are the cheapest feeds, followed closely by malt sprouts, dried distillers' grains, corn meal, and

gluten feed. The relative prices may vary somewhat in different localities, but in general it is probably safe to say that these will be the cheapest feeds this season. The most expensive feed . . . [included in the comparison] is alfalfa meal, the next most expensive linseed meal."

The chemical and physiological properties of cell walls, A. FÜRSTENBERG, R. MURDFIELD, and J. KÖNIG (*Landw. Vers. Stat.*, 65 (1906), No. 1-2, pp. 55-110).—The chemical and physiological experiments reported led to a number of conclusions, among which are the following:

The glycerin-sulphuric acid method was found to be satisfactory even for cellular tissue rich in pentosans. When the crude fiber of feces was treated with glycerin-sulphuric acid, the hemicelluloses and the pentosans were very thoroughly dissolved, so that this method seems the preferable one even for materials rich in lignin. The difficultly soluble portion of cell membrane designated crude fiber in food and feeding stuff analyses consists of 3 groups of different properties and with different carbon content, namely, (1) a cellulose group with 44.44 to 46 per cent carbon, which is soluble in copper oxid and ammonia; (2) the portion of the lignin group which can be oxidized with hydrogen peroxid and ammonia and has a carbon content of 55 to 60 per cent; and (3) "kutin," which has even a higher carbon content and is not oxidized by either of the reagents mentioned. The cellulose group is quantitatively soluble in copper oxid and ammonia only after the removal of the portion which can be oxidized. The crude fiber which remains after the removal of lignin and kutin and which is soluble in copper-oxid ammonia and gives a violet color with chlorid of zinc and iodine and a blue color with sulphuric acid and iodine, does not always possess the composition of true cellulose, but sometimes shows a higher carbon content owing to the addition of methyl or methoxyl groups. Such cellulose has been identified in rye and wheat bran and in very small quantity in barley bran.

Methoxyl, ethoxyl, or acetyl groups are present in larger proportion in lignin, but are entirely absent in kutin. Lignin is evidently not a simple body, but consists of a number of carbon radicals united to cellulose.

The proportion of kutin in crude fiber is by no means small. According to the analyses which have been made it ranges from 0.64 per cent in pea bran to 13.67 per cent in wheat bran, and from 0.76 per cent in pea bran feces to 19.05 per cent in wheat bran feces.

As is well known, the percentage content of crude fiber in plants increases with age. On the other hand, the lignin content increases more rapidly than the cellulose. No fixed relation is apparent between kutin content and plant growth.

The digestibility of the cell membrane of coarse fodders by sheep is inversely proportional to the lignin and kutin content. Cellulose is the most thoroughly digested of the crude fiber constituents. Lignin is very resistant to the digestive juices of herbivora and is only utilized to a very small extent. If kutin is utilized at all it is only in very small quantity and when it occurs in very young plants. With pigs the digestibility of the crude fiber of bran, with the exception of pea bran, is very slight, as is also the case with rabbits. That portion of the crude fiber which contains the lower percentage of carbon has a higher digestibility than the portion with the high carbon content. These animals also digest kutin very little if at all.

Since the digestibility of crude fiber in general is inversely proportional to the lignin and kutin content, it seems probable that the lignin and kutin, or the latter alone, surrounds the cellulose or is deposited in it in such a way that the action of the digestive juices is hindered. These things being so, it is

very desirable to determine the proportion of lignin and kutin in feeding stuffs in order that an estimate of their true value may be made.

The use of locusts as food, H. INGLE (*Transvaal Agr. Jour.*, 5 (1906), No. 17, pp. 111-116).—Analyses of sun-dried locusts which have been killed by half-hour immersion in boiling water showed that they contained on an average 10.31 per cent water, 57.96 per cent protein, 11.05 per cent fat, 11.26 per cent crude fiber, and 5.31 per cent ash. The author states that there was also a small quantity of some sugar-like compound, the nature and amount of which was not determined and which was possibly derived from the food present in the insects' stomachs. The silica, lime, potash, and phosphoric acid content of the locusts were also determined, the average phosphoric acid content being 1.48 per cent.

As pointed out, the dried locusts resemble some of the commercial feeding stuffs of animal origin and their use is recommended for farm animals. As shown by the results of practical experience, they have been particularly useful as a poultry feed and a pig feed. Many farmers believe that locust meal produces large yolks of a richer color than usual and that they do not affect the flavor of eggs. Furthermore, locusts are "well worth collecting and killing for manurial purposes. Their value as a fertilizer is very great, because of their richness in nitrogen and phosphoric acid."

Farm animals, E. V. WILCOX (*New York: Doubleday, Page & Co., 1906*, pp. 17 + 357, pls. 63).—The characteristics of different breeds, the principal problems which must be met in the feeding and care of farm animals, the importance of different feeding stuffs, animal diseases and their treatment, and other questions regarding the production, feeding, care, and management of farm animals are considered in this volume, which constitutes an important summary of available data. Notable features of the volume are the extensive use which has been made of the results obtained by experiment station investigators, and the scope and accuracy of the data presented. Special chapters are devoted to the horse, mule, beef cattle, dairy cows, pigs, sheep, goats, and poultry.

Steer feeding, J. H. SKINNER and W. A. COCHEL (*Indiana Sta. Bul.* 115, pp. 311-337, figs. 6).—Using 3 lots of 11 steers each the efficiency of various combinations of corn and other feeds, such as corn stover, oat straw, and clover hay, commonly available on Indiana farms, was studied.

On ear corn and clover hay, the average daily gain per steer in the 180 days of the test was 2.08 lbs. On ear corn, shredded corn stover, oat straw, and a little linseed meal, the gain was 1.78 lbs. per head per day, and on a similar ration without linseed meal the gain was 1.30 lbs., the cost of a pound of gain in the 3 cases being 6.59, 7.79, and 8.46 cts. The smallest grain ration, 17.59 lbs. was fed to the lot receiving ear corn, shredded stover, and oat straw, and the largest grain ration, 20.45 lbs., to the lot given the linseed meal. The last-mentioned lot received the smallest amount of coarse fodder, 7.02 lbs., and the lot fed clover hay the largest amount, 8.32 lbs.

Pigs sufficient in number to gather the undigested feed followed the steers and produced 2.10 lbs. of pork per bushel of corn on the clover-hay ration, 1.80 lbs. on the ration containing linseed meal, and 1.78 lbs. on the ear corn, shredded stover, and oat straw ration.

Some of the conclusions drawn were in effect as follows: The ear corn, shredded stover, and oat straw ration was neither efficient, economical, nor profitable. The addition of a nitrogenous feeding stuff, either in the form of a concentrated feed or coarse fodder, added to the efficiency of the ration and the profit of the feeder. The concentrated feeds tested, namely, clover hay and lin-

seed meal, both proved satisfactory. The steers fed the ration containing linseed meal were as well finished as those receiving the clover-hay ration, although they made smaller gains.

The feeding of beef cattle, T. BUTLER (*Bul. N. C. Dept. Agr., 27 (1906), No. 5, pp. 27, figs. 6*).—In the author's opinion the feeding of beef cattle in North Carolina should be increased and may be profitably practiced to insure the utilization of local-grown feeding stuffs and consequent improvement of soils.

The available concentrated feeds, he points out, are cotton seed and cotton-seed meal and the coarse fodders shredded corn stover and silage and under certain conditions cotton-seed hulls, pea vine, sorghum, and other home-grown hays.

"To the concentrates named it may be profitable in certain cases to add a small quantity of corn, or corn and cob meal, but this is extremely doubtful.

"This does not afford us a very large variety of feeding stuffs, and yet it is quite practicable to feed cattle for from 4 to 6 months on corn stover, silage, cotton seed and cotton-seed meal with quite satisfactory results both as regards the daily gains made by the cattle and the financial returns from the operation. . . . The usual high price of corn precludes its extensive use in this State. . . .

"The same facts and reasoning as above applied to the feeding of corn probably also apply to all other high-priced grains or concentrates, such as wheat bran, rice products, gluten feeds, etc. In long feeding periods, small quantities of these feeds may possibly be used advantageously, but even this is doubtful, and it is quite certain that as a general rule the average feeder will not find their use profitable in any quantity."

Sample rations are suggested suitable for different breeds of fattening steers.

In a discussion of feed lots and shelters, the feeding barn and lots in use at a test farm of the State department of agriculture are described.

Cattle-feeding experiment, W. BRUCE (*Edinb. and East of Scot. Col. Agr. Bul. 10, pp. 25-36*).—A liberal v. a limited ration of turnips and moderate v. heavy feeding was studied in continuation of earlier work (*E. S. R., 17, p. 1003*) with 3 lots of 8 steers each, the feeding period covering 138 to 150 days.

On a ration of 90 lbs. turnips with oat straw ad libitum and a daily allowance of 6 lbs. of Bombay cotton-seed or other cake the average daily gain per head was 1.78 lbs. With both turnips and straw ad libitum and the same amount of cake as before the average daily gain was 1.75 lbs. per head. When the cake was increased 50 per cent and the turnips and straw were the same as with the first-mentioned lot the average daily gain was 2.02 lbs. per head. The cost of a pound of gain in the 3 cases was 12 cts., 13 cts., and 11.9 cts., respectively.

A similar lot of 8 cattle was fed, at the time of the above test, for 120 days turnips and straw with a variety of concentrated feeds and made an average daily gain of 2.05 lbs. per head, the cost of a pound of gain being 12.5 cts.

Sheep-feeding experiment, W. BRUCE (*Edinb. and East of Scot. Col. Agr. Bul. 10, pp. 1-12*).—Continuing earlier work (*E. S. R., 17, p. 896*) different concentrated feeds were tested, turnips and hay constituting the coarse fodder of the rations. The special feeds were Bombay cotton-seed cake alone and mixed with linseed cake and crushed oats, linseed cake, dried distillers' grains, and decorticated cotton-seed cake with crushed maize. Each lot contained 30 sheep and the test covered 85 days.

The greatest gain, 2.54 lbs. per head per week, was made on the linseed cake ration and the smallest gain, 2 lbs. per head per week, on the Bombay cotton-seed cake and oats 1:1. With the latter ration the gain was most expensive,

costing 9.28 cts. per pound. The gain was most cheaply made on the dried distillers' grains, costing 8.6 cts. per pound.

One of the points discussed in the report is the returns obtained per acre from the turnips used in the various rations.

Feeding fermented cotton-seed meal to hogs, F. R. MARSHALL. (*Texas Sta. Bul.* 78, pp. 20, figs. 8).—Since it has been claimed that feeding fermented cotton-seed meal to pigs by the so-called Allison method gives satisfactory results inquiries were sent to a number of feeders in Texas requesting data based on their experience, and a feeding test was undertaken in which fermented cotton-seed meal and corn chops 1:2 and 1:1 were compared with corn chops fed in the usual way and fermented. There were 10 pigs in each lot and the test covered 83 days.

The lot fed unfermented corn chops made an average daily gain of 0.49 lb. per head at a cost of 8.4 cts. Similar values for the lot fed fermented corn chops were 0.39 lb. and 9.57 cts. The feed eaten per pound of gain in the 2 cases was 7.62 and 8.68 lbs. The lot fed fermented cotton-seed meal and corn chops 1:2 made an average daily gain of 0.46 lb. per head at a cost of 8.06 cts., 7.27 lbs. of feed being required per pound of gain. One of the pigs in this lot died very near the end of the experimental period and another ceased to make gains, and so was not marketed with the rest of the lot. The pigs fed fermented cotton-seed meal and corn chops 1:1 made an average daily gain of 0.34 lb. at a cost of 11.1 cts., 10 lbs. of feed being required per pound of gain. Sickness was noted in this lot as early as the sixty-fifth day of the trial and 3 pigs died before its close.

The results of slaughter tests made with the 4 lots are reported. The principal conclusions which were drawn from the test as a whole follow:

"The reports of feeders who have used cotton-seed meal for hogs indicate that a light feed of cotton-seed meal may be continued indefinitely and that the consumption of green feed lessens the danger of death from feeding cotton-seed meal.

"A comparison of the results of this experiment with those of other stations at which cotton-seed meal was fed in the ordinary way indicates that cotton-seed meal may be used in larger quantities and for longer periods when fermented and fed in a slop than when fed without being fermented.

"In this trial the hogs were yard fed during the hot summer season, consequently they were under conditions making the trial as severe as possible. Under such conditions fermenting cotton-seed meal does not entirely remove its injurious effect when fed to hogs.

"The results of this experiment show that for the first 43 days of the feeding the mixture containing cotton-seed meal and corn gave larger and cheaper gains than the straight corn ration, while during the second period of 40 days the results were reversed. This leads to the suggestion that, to improve a corn ration, it would be advisable to add cotton-seed meal to it for about 40 days, preferably, for other reasons also, during the last 40 days of the feeding.

"The hogs that received cotton-seed meal as a part of their ration in this trial showed less fat and more lean meat in the carcass.

"The carcasses of the hogs that received cotton-seed meal, contrary to the previously expressed opinion of the packers, were firmer and therefore more acceptable to them than those of the corn-fed hogs."

To those who wish to feed cotton-seed meal to pigs, the author recommends that for animals on heavy feed not more than one-fourth of the total weight of the grain ration consist of cotton-seed meal. This feeding should not be continued for more than 50 days unless the proportion of cotton-seed meal be

reduced. The meal should be mixed with the other feed and all soured together. As much green feed as possible should also be fed and a close watch kept and the cotton-seed meal taken away from any animals not eating or not gaining well.

If cotton-seed meal and corn chops are mixed before the water is added the tendency for the meal to form into balls is obviated. In summer the mixture will sour readily in 24 hours. In cold weather 48 hours or longer will be required to produce the characteristic sharp odor. Souring will be hastened by adding to each lot of feed a quart of the sour material.

"Feeders who have had experience with the meal will probably be able to exceed these recommendations, which, however, allow the use of enough meal to greatly improve a corn diet. One lb. of cotton-seed meal to 5 of corn furnishes the nutrients in the most desirable proportions for fattening, while 1 to 2 of corn are more nearly correct for young growing stock. Of course other feeds are desirable for their influences not attributable to their composition, but it is not often that the adopted standards can be ignored in feeding any animals for profit."

Egg farming—infertile eggs, M. FERN (*Queensland Agr. Jour.*, 17 (1906), No. 5, pp. 229, 230).—The superiority of infertile eggs is insisted upon, and a test is briefly reported in which a large proportion of such eggs, stored at ordinary temperatures, kept fresh for more than 2 months.

Ostrich farming as carried on at the present day, A. W. DOUGLASS (*Transvaal Agr. Jour.*, 5 (1906), No. 17, pp. 92-95).—The present systems of ostrich farming in the Transvaal are pasturing on alfalfa or feeding alfalfa hay and ranching the ostrich or running the birds in camps on the natural veld. Some advantages of each of the two systems are briefly described and data given regarding ostrich enemies and parasites.

"The two great scourges to the ostrich farmer are that the birds in their younger stages are invariably infested with tapeworm, and still worse with Douglassi or wireworm. These are overcome to a great extent by dosing the young birds with turpentine and other mixtures, and the older the bird becomes, the freer it becomes of these parasites; the reason why is as yet unknown."

The turtle trade of the West Indies, W. G. FITZ GERALD (*Sci. Amer.*, 95 (1906), No. 20, pp. 365, 366, figs. 4).—Turtle fishing, feeding, marketing, the manufacture of canned and bottled turtle products, and other features of the West Indian turtle trade, which centers at Kingston, Jamaica, are discussed.

DAIRY FARMING—DAIRYING—AGROTECHNY.

Experiments for the determination of the protein minimum in rations for dairy cows (*Ber. K. Vet. og Landbohøjskoles Lab. Landøkonom. Forsøg [Copenhagen]*, 60 (1906), pp. 1-147+1-158).—The investigation reported in this publication was conducted for the purpose of determining the quantities of nitrogenous substances required by milk cows, especially minimum protein requirements.

Nine fresh cows were placed on the experiments planned for the study of this question, and were fed rations containing varying proportions of hay, straw, mangels, and cotton-seed meal. The nitrogen balance was determined throughout the experiments by collecting the solid and liquid excreta, which were weighed and analyzed as in the case of the feeding stuffs used on the experiments.

The following table gives a summary of the average results obtained. These are published, however, as only approximate figures, since the minimum must

necessarily vary considerably with different cows, according to their ability to utilize their feed, the kind and quality of the feed eaten, and the amount and character of milk produced, especially its nitrogen content.

Approximate minimum of nitrogen for dairy cows.

Daily yield of milk.	Rations fed.				Total nitrogen.	Nutritive ratio.
	Cotton-seed meal.	Mangels.	Hay.	Straw.		
Kg.	Kg.	Kg.	Kg.	Kg.	Grams.	
16	1.50	45	2.5	5	200	1.9
13	1.25	48	2.5	4	182	1.10
10	1.00	51	2.5	4	165	1.11

It will be seen that the minimum protein content of rations for milch cows, according to these results, will range between 2.75 and 2.28 lbs. for cows producing 35 to 22 lbs. of milk containing 3 to 4 per cent of fat. In the rations as fed, these amounts corresponded to about 2.06 to 1.70 lbs. of digestible protein per head daily.

The conditions under which changes occur in the protein requirements of dairy cows and the physiological effects of variations in the supply of protein in the rations are discussed at considerable length in the report, as well as the bearing of the results of the investigation on mooted questions of methods of study of feeding problems with dairy cows.—F. W. WOLL.

The fat content of cows' milk, its normal variations and transmission, K. A. HÖGSTRÖM (*K. Landtbr. Akad. Handl. och Tidskr.*, 45 (1906), No. 3-4, pp. 137-176).—This investigation was conducted with a large herd of pure-bred or high-grade Ayrshire cows during a period of eight years, the object in view being to study the causes of normal variations in the fat content of cows' milk, aside from immediate changes brought about through the influence of differences in weather or temperature conditions, manner of feeding, etc., and to determine, if possible, the laws of transmission of the quality of the milk. The material at hand included nearly 18,500 fat determinations in the milk from 393 cows. These calved throughout the year, although more freshened during the fall months than in the spring.

The author discusses variations in the fat content of milk under three headings—accidental variations, depending on exterior influences affecting the nervous system of the cows; normal variations, based upon the nature of the cows; and individual variations, depending on hereditary influences. Only influences coming under the last two headings are discussed in this paper.

Under normal variations are considered the following:

(1) The periodical variation for the lactation of the cow: The fat content of the milk, which at the beginning of the period is above average, falls rapidly and reaches its minimum during the third month from calving, after which there is a gradual increase until a maximum is reached at the close of the lactation. The average data for all cows obtained by the author for the first to the thirteenth months from calving were as follows: 3.75, 3.57, 3.50, 3.54, 3.61, 3.67, 3.78, 3.89, 3.99, 4.09, 4.14, 4.13, and 4.15 per cent.

(2) The periodical variation for the life of the cow: The fat content is highest at three years of age, is high at four years, and remains close to the average for the family during the full activity of the cow, after which it again rises slightly. The average of all data was as follows: Third year, 3.83 per cent; fourth, 3.74 per cent; fifth, 3.65 per cent; sixth, 3.65 per cent; seventh, 3.66 per

cent; eighth, 3.69 per cent; ninth, 3.65 per cent; tenth, 2.67 per cent; and over 10 years, 3.75 per cent; general average of 799 lactations, 3.69 per cent.

(3) Variations according to the month of the year: Normal fat content in April, strong depression in May, June (minimum, 3.45 per cent), and July; again average in August and rapid increase in September, with maximum (3.96 per cent) in October; and slightly varying fat contents during the winter months.

(4) Variations according to the place of the month of calving in the calendar year: Increased average fat contents in periods beginning in March, August, and September, and decrease in periods beginning in May and October. This variation is a direct result of the preceding one.

(5) The different power of cows for larger or smaller production: Cows yielding abnormally little milk have higher fat contents, and an abnormally high milk yield is accompanied by a lower fat content, while a milk yield falling within the natural variations of a family shows a normal fat content.

(6) Changes in the normal milk production depending upon changes in the system of feeding: The milk yield stands in an inverse ratio to the fat content. The variation refers to an entire year and months, as well as to short periods. The variations in the fat content are, however, much smaller than that of milk production.

The curve for the average monthly fat content of the milk for the calendar months April to October was found to correspond in a striking manner to the corresponding part of the curve for cows calving in March to April, and the author traces the cause on the hypothesis that March and April is the natural calving time for cows, and that they, therefore, continue to change the fat content of the milk throughout the summer months in such a way as is best for the calf when dropped at normal calving time. It is also shown that the difference in the production of milk and fat during an entire lactation period caused by the time of calving are very marked, amounting in the case of cows calving in March and in August to about 18 per cent. In general, the milking periods commencing during the winter months give larger yields than those that commence during the summer.

The influence of the individual variations was studied by the statistical method, as was that of the normal variations. In this case, however, no such large material was available. The largest series that was obtained consisted of 76 daughters, but most of these, as well as their dams, were tested for more than a year. In all, 584 determinations of the yearly fat production were made in the case of the progeny of, or dams mated to, the four bulls included in the investigation. Briefly stated, the conclusions drawn from this study are as follows: The lower the fat content of the dam's milk, the more that of the daughters is increased by the sire. If the fat contents of both parents appreciably exceeds that of the average for the family, their united influence is not able to increase the fat content of the daughters to the average of that of the parents, against the influence of the family, but it will remain below that of the parents. The fat content of the daughters is never the average of that of the parents, but comes near to the average of the family. While the variations studied in these investigations can not be taken to apply in all details to other herds and breeds of cattle, they may safely, in the author's opinion, be considered of general value, with the distinct limitation that their extent and their development in certain directions may vary in different families and breeds.—

F. W. WOLL.

Cow testing associations, with some notes on the sampling and testing of milk, J. A. RUDDICK and C. F. WHITLEY (*Canada Dept. Agr., Dairy Comr.*

Branch Bul. 12, pp. 14, figs. 5).—More than 20 cow-testing associations have been organized in the provinces of Ontario and Quebec and the movement is said to be extending rapidly. This bulletin serves as a sort of popular manual for this purpose, as it contains rules and regulations for such organizations and directions for carrying on the work.

Milking machines, O. ERF (*Kansas Sta. Bul. 140, pp. 67, figs. 50).*—This bulletin contains a statement of the principles upon which milking machines have been constructed; illustrated descriptions of over 70 of the more important machines, classified under milk tubes, pressure machines, and suction machines, which have been invented since the practical beginning of work along this line in 1878; detailed directions for installing and operating milking machines; and a report upon experiments conducted at the Kansas Station.

The success of machine milking in practice as compared with hand milking depends, according to the author, upon several factors, among which are the reduction in cost of labor, maintenance of both the quantity and quality of the milk, cleanliness of the milk, the possibility of using the machine for the average cow, reliability of the machine, and the returns for the capital invested.

In securing data upon the reduction and cost of labor, hand milking and machine milking were compared at intervals on 17 cows. Averaging the data for 3 milkers, it was found that the time required to milk a cow was 9.14 minutes and the yield of milk 12 lbs. or 1.27 lbs. per minute. With a milking machine, the time required to milk two cows averaged 7.1 minutes, the rate per minute being 2.3 lbs. Three machines managed by 1 man would, therefore, according to these results, be better than five milkers, but this takes into consideration only the time actually employed in milking and not that required for putting the machine in operation, taking care of the engine, etc.

The author considers that sufficient experimental work has been done to prove that no great decrease in the quantity and quality of milk can result from the use of milking machines. The results of 32 tests showed that the average cow was milked slightly cleaner by machine than by hand.

In 12 experiments, milk taken from the milking machine remained sweet for a longer time, varying from 1 to 10 hours, than that obtained by hand, the samples in both cases being kept under identical conditions at a temperature of 60°. At 32°, machine-drawn milk remained sweet 6 to 38 hours longer than that obtained by hand. Bacteriological tests also showed the superiority of the milking machine over hand milking as regards cleanliness.

Tests were made of boric acid, lime, and formaldehyde for sterilizing the milking machine. One per cent solution of formaldehyde was the most effective. Boric acid was the most expensive and least effective, but did not injure the tin. Lime, on account of its cheapness, is considered the most practical where large quantities of antiseptic materials are to be used.

In no instance did cows indicate any discomfort from the use of the machines. The machines used at the station have been found to be very durable.

The author considers that for a small dairy the investment in a milking machine at present prices would be unprofitable. For dairies of 50 cows or more, however, it is considered a good investment. Several tests were also made as regards the most satisfactory number of pulsations per minute and the proper amount of vacuum. With the machine used, this was found to range from 45 to 53 pulsations per minute and 16 to 17 lbs. of pressure.

On the formation of lactose, F. H. A. MARSHALL and J. M. KIRKNESS (*Bio-Chem. Jour., 2 (1906), No. 1-2, pp. 1-6).*—The experiments here reported were undertaken to test P. Bert's hypothesis recently supported by the work of Porcher (E. S. R., 17, p. 287) that lactose is formed in the mammary gland from glucose in the blood. The work consisted in removing the mammary glands

from guinea pigs and testing for glycosuria before and after a subsequent parturition. Three experiments failed to show any glycosuria following parturition nor any increase in the glucose in the blood at that time. On the other hand, a glycosuria was occasionally observed after parturition in normal unoperated animals. It is considered probable that the glycosuria observed by Porcher was a post-operative effect. This work, therefore, confirms the view that the complete process of lactose formation takes place in the cells of the mammary gland.

Homogenized milk, M. J. EURY (*Indus. Lait, [Paris], 31 (1906), No. 48, pp. 777-779*).—Analyses were made of raw and sterilized milk before and after treatment by the method of Gaulin. In the untreated milk the fat globules were often 10 microns in diameter, while in the homogenized milk they scarcely reached a diameter of 3 microns. The determination of fat by the Gerber method showed a lower percentage as a result of treatment. The Adams method, however, was unaffected. The same result was obtained by the Gerber method when the period of centrifuging was prolonged to 10 minutes. In general, the composition of the milk before and after homogenizing was identical, showing that this treatment did not modify the composition of the milk.

Investigations on the source and distribution of organisms of ropy milk, M. SCHNEEBELI (*Schweiz. Milch. Ztg., 1906, No. 45; abs. in Rev. Gén. Lait, 6 (1906), No. 2, p. 44*).—The lactic bacteria capable of producing viscous fermentation are not believed to be widely distributed. Occasionally, however, a dairy may become badly infected with such organisms. An instance of this kind was investigated.

The pathogenicity of *Streptococcus lacticus*, P. G. HEINEMANN (*Jour. Infect. Diseases, 4 (1907), No. 1, pp. 87-92*).—Brief reference is made to investigations bearing upon the pathogenic action of streptococci isolated from milk, the conclusion being drawn from the review that such organisms, when freshly isolated and not originating from mastitis do not possess high virulence. In an earlier article (*E. S. R., 17, p. 1007*) the author reported the constant occurrence of *Streptococcus lacticus* in milk and considered this organism identical with *Bacillus lactis acidi* and also identical in morphological and cultural characters on ordinary media with *S. pyogenes*.

In the present investigations the aim was to determine if the virulence of *S. lacticus* might be increased by successive passages through animals. Five strains of *S. lacticus* from different sources and three of *S. pyogenes* were used. The conclusion drawn from the investigations is that these two organisms are closely related not only in morphological and cultural characters but in pathogenic properties. The virulence of *S. lacticus* was gradually increased by repeated passages through rabbits so that after five or more passages, 2 cc. of a 24-hour-old broth culture was fatal in subcutaneous injections. The same amount injected intravenously was fatal to the first animal. The lesions of *S. lacticus* in rabbits were the same as those produced by *S. pyogenes* in man.

Report of the butter laboratory in Hängo, Finland, 1904, G. A. BREDBERG (*Landbr. Styr. Meddel., 52 (1906), pp. 30*).—The report gives an account of the first year's work of the laboratory established in connection with the Finnish export butter exhibits. The output of 221 creameries was examined during the year. The results of the determinations on 1,051 samples of the refractive index and contents of volatile fatty acids, respectively, by months are as follows: January, 50.5, 30.4; February, 50.4, 30.8; March, 50.9, 31.1; April, 50.4, 31.8; May, 51.8, 31.9; June, 51.4, 30.4; July, 52.1, 29.3; August, 52.8, 28.2; September, 53.0, 27.8; October, 51.9, 28.4; November, 50.5, 29.7; December, 50.0, 31.7; maximum, 54.0, 33.7; minimum, 49.0, 25.9; and average, 52.5, 28.0.

No relation could be traced between the volatile-acid content of the butter fat and the quality of the butter. The average water content of all samples examined was 13.59 per cent, the extremes being 10.24 and 18.72 per cent. Of the samples examined 79.1 per cent contained between 12 and 15 per cent of water, and only 3.9 per cent contained more than 16 per cent. The water content of the butter was, as a rule, somewhat higher during the pasturing season than on stable feeding, the averages being respectively 13.63 and 13.44 per cent.—F. W. WOLL.

The butter trade in Denmark, France, and Holland, HOLLMANN, HAILER, and I. FROST (*Ber. Land u. Forstw. Auslande, 1906, No. 13, pp. 38*).—This contains statistical and other information concerning the sale of butter in these countries.

Influence of pepsin upon the ripening of Limburg cheese, L. MARCAS and C. HUYGE (*Rev. Gén. Lait, 6 (1906), No. 2, pp. 25-33*).—A series of experiments were undertaken to determine the influence of pepsin on the ripening of this cheese. According to the results obtained, the addition of rennet increased the amount of soluble nitrogenous products. The increase, however, was not proportional to the quantity of pepsin added. The influence of pepsin was most marked during the first few weeks following the manufacture of the cheese, when the acidity was high. While the analytical results show, therefore, that pepsin plays a useful rôle in the ripening of this cheese, the judgment of experts on the quality of the cheese was not in accord with this view. Chemical analysis as a means of determining the ripening of cheese is therefore considered of doubtful value.

Action of rennet on milk, B. SLOWITZOFF (*Beitr. Chem. Physiol. u. Path., 9 (1907), No. 3-4, pp. 149-152*).—The results of experiments by the author agree with those of Petry (*E. S. R., 18, p. 475*) in that whey albumin is not formed solely at the time casein is changed into paracasein, but continues to increase in amount after that stage. According to the author, rennet must either be considered as containing two ferments—one coagulating and one proteolytic, or that coagulation with rennet is merely the first step in the digestion of the casein.

Fundamental dairying and dairy arithmetic, O. ERF (*Manhattan: Kausas Agr. Col., 1906, pp. 49*).—This constitutes a popular treatise in the form of questions and answers. Particular attention is paid to calculations of use in dairying.

First national congress of dairying (*1. Cong. Nat. Indus. Lait., 1906, Année Rap. et Compl. Rend., pp. 148-250*).—This is a report of the proceedings of the French Dairy Congress held in Paris, March 12-13, 1906. Papers were presented upon the cooling of milk, the physical condition of cream, pasteurization in butter making, the food value of casein, and the selection of cows. Reports on 15 dairy subjects were also made and discussed.

Pure yeast in wineries, F. T. BIOLETTI (*California Sta. Circ. 23, pp. 4*).—The author does not advocate the general use of pure yeasts in wine making at the present time. Under favorable conditions, however, the method is believed to have decided advantages, such as a thorough fermentation, a rapid clearing, and an absence of the disagreeable flavors of secondary fermentation. These benefits which have been demonstrated by both laboratory and cellar experiments are, however, not to be secured unless special care is exercised. This circular is, therefore, intended for the more progressive wine makers who desire to improve their product.

The station has isolated a yeast which has uniformly given good results in practical tests and has prepared a small quantity for distribution to a limited

number of wine makers. Directions for the use of pure yeasts are given in this circular.

Defecation of must for white wine, F. T. BIOLETTI (*California Sta. Circ.* 22, pp. 4).—A method of using sulphur fumes for this purpose is given and arguments in favor of the process are summarized as follows: "(1) It eliminates the worst of the impurities before they have contaminated the wine; (2) it diminishes the amount of sediment in the casks at the first racking; (3) it causes the wine to clear much more rapidly after fermentation; (4) it eliminates much of the albuminoid substances which are the preferred food of injurious bacteria; (5) it clears the wine of most of the molds, wild yeasts, and bacteria; and (6) it enables us to use pure yeast with the greatest effect."

Beet-sugar manufacture, H. CLAASSEN, trans. by W. T. HALL and G. W. ROLFE (*New York: John Wiley & Sons; London: Chapman & Hall, Ltd., 1906*, pp. XVI+280).—This is an authorized translation from the second German edition of this treatise.

A practical handbook on the distillation of alcohol from farm products and the denaturing of alcohol, F. B. WRIGHT (*New York: Spon & Chamberlain; London: E. & F. N. Spon, Ltd., 1906*, pp. VIII+194, figs. 33).—This treats of the various sources of alcohol and the methods by which it is obtained, methods of determining the quantity of alcohol in spirituous liquors, and the preparation and use of denatured alcohol.

VETERINARY MEDICINE.

Treatise on domestic animals in health and disease, A. KOCH (*Lehre von den Gesunden und Kranken Haustieren. Vienna: M. Perles, 1907*, pt. 1, pp. VI+314, figs. 291).—The present volume is intended to show in its treatment of the subject the relationship between veterinary science and modern agriculture. In the care of domestic animals considerable knowledge of the anatomy, physiology, and common diseases is necessary in order to make a success of the business. The author has presented the material contained in the volume especially for the use of students and stock raisers.

Part 1 relates to the conditions of health in domestic animals and includes a discussion of the cellular structures and organs of locomotion, digestion, circulation, and other parts of the body.

A text-book upon the pathogenic bacteria, J. MCFARLAND (*Philadelphia and London: W. B. Saunders Co., 1906*, 5. ed., pp. 648, figs. 180).—In preparing the present edition of this text-book, the chapters on infection and immunity have been entirely rewritten in order to bring them abreast of modern research. The volume contains a general account of the growth and distribution of pathogenic bacteria on various substances. Specific descriptions are given of the common infectious diseases of man and animals.

The toxins and venoms and their antibodies, E. POZZI-ESCOT, trans. by A. I. COHN (*New York: John Wiley & Sons; London: Chapman & Hall, Ltd., 1906*, 1. ed., pp. VII+101).—Research in the field of toxins has been so active in the past 20 years that convenient handbooks dealing with the essential points have become a practical necessity. The present treatise contains an account of alkaloid toxins, bacterial toxins, vegetable toxins, and venoms as obtained from various species of animals.

The rôle of leucocytes in the defense of the organism against infection, M. PETERSSON (*Centbl. Bakt. [etc.], 1. Abt., Orig., 42 (1906), No. 1*, pp. 56-63).—The author's experiments were carried out on guinea pigs and rabbits with cultures of vibrio. In order to note the action of leucocytes upon the

pathogenic organism these corpuscles were transferred from one animal to another which had recently been inoculated. The author concludes from his experiments that the serum and leucocytes cooperate in protecting the animal organism against infection. In this work the serum attacks the bacteria directly, while the leucocytes assist in counteracting and destroying bacterial toxins.

Causes of the diminution of natural resistance to infection, R. THOMSDORF (*Arch. Hyg.*, 59 (1906), No. 1, pp. 1-90).—The present article is a contribution to the study of immunity. The author carried on an extensive series of experiments, the results of which interpreted partly in the light of other experiments along the same line may be briefly summarized in the statement that while there may be other factors in determining the degree of immunity, the motile power of the leucocytes, the ability of certain cells to form alexins, and the power of the organism to produce specific protective bodies are the chief factors concerned.

The relation of autolysis to the histological changes occurring in necrotic areas, H. G. WELLS (*Jour. Med. Research*, 15 (1906), No. 1, pp. 149-165).—A chemical and histological study was made of the changes which take place during the necrosis of the tissue. There is first a decomposition of the nucleoproteids in ordinary infarcts. The proteid structure of the cell is attacked by proteolytic enzymes and such infarcts are absorbed through a digestive action of the leucocytes.

Report on the proceedings of the free society for micro-biology in the institute for infectious diseases in Berlin, A. WASSERMANN (*Centbl. Bakt. [etc.]*, 1. Abt., Ref., 38 (1906), Beiheft, pp. 120, pl. 1).—The free society for microbiology met in Berlin, June 7-9, 1906, and at these meetings a large number of papers dealing with bacteriological problems was read. The author has prepared a summary of the most important points contained in these papers. Particular attention was given to a discussion of the problems of immunity, the general one being stated by R. Kraus; immunity toward anthrax, by Gruber; toward vibrio in pigeons, by R. Pfeiffer and R. Scheller; and toward plague, by Löhlein. Among the other matters of interest from the veterinary standpoint were a discussion of the quantitative relation of tubercle bacilli to infection, by Flügge; the properties of serum in cases of tuberculosis, by Sobernheim; and the etiology of roup, by R. Müller.

Transmission of resistance to diphtheria toxin by the female guinea pig to her young, J. F. ANDERSON (*Jour. Med. Research*, 15 (1906), No. 2, pp. 241-260).—The possibility of the transmission of immunity to disease is being studied from every standpoint, and the present article is a distinct contribution to the subject in that the author's experiments showed that ordinarily all of the young of different litters from a female guinea pig previously immunized to diphtheria were in turn immune to the disease. Such immunity, however, was not transmitted to the second generation. A distinct cumulative effect was observed from the repeated use of diphtheria toxin. In further experiments it was found that the female guinea pig may transmit simultaneously to her young an immunity to diphtheria toxin and a greatly increased susceptibility to horse serum.

The pathogenic action of blastomycetes injected into the trachea, F. SANFELICE (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 41 (1906), Nos. 1, pp. 61-71; 2, pp. 195-200; 3, pp. 332-338, pl. 1).—The author's experiments were made on guinea pigs and rabbits, and a considerable variety of blastomycetes were used, including *Saccharomyces canis* and *S. ucoformans*. The effect upon the tissue

of the trachea varied in different cases. Giant cells were sometimes formed by the fusion of epithelial cells.

It appeared during these experiments that the differences between malignant growths and benign forms of irritation set up by organisms such as those used by the author are not always sufficiently striking to enable one to make the diagnosis.

Experiments in examination of the locked jaw induced by tetanus toxin, H. E. ROAF and C. S. SHERRINGTON (*Jour. Physiol.*, 34 (1906), No. 4-5, pp. 315-331, charts 4).—The experiments, the results of which are here reported, were carried out on monkeys.

It appeared that after the division of the lower jaw at its symphysis the stimulation of the corresponding area of the brain cortex caused an opening of the jaw. After inoculation of the facial nerve with tetanus toxin the stimulation of the same area of the brain caused a closing of the jaw. This change was more pronounced during the early stages of intoxication. The authors are of the opinion, however, that the cerebral cortex was not affected by the tetanus toxin, but the changes in the reactions obtained took place in some of the lower brain centers.

The treatment of tetanus by the method of Baccelli, G. BIANCHEDI (*Clin. Vet. [Milan]*, 29 (1906), No. 39, pp. 937-951).—The results obtained by the author in experiments with this method agree largely with his own observations in indicating for it great practical utility, but not an absolute infallibility.

Danysz' reaction, T. MADSEN and S. ARRIENIUS (*Meddel. K. Vetensk. Akad. Nobelinst.*, 1 (1906), No. 3, pp. 1-20, figs. 3).—In a study of the reactions between the toxin of tetanus and its antitoxin, it has been demonstrated that after the tetanus toxin has been neutralized by the antitoxin a new reaction takes place if the antitoxin is in excess. This second reaction consists in a fixation of a relatively large amount of antitoxin and is known as Danysz' reaction. The reaction depends upon the excess of antitoxin over the toxin.

Infection in tuberculosis, A. E. METTAM (*Vet. Rec.*, 19 (1906), No. 951, pp. 182-186).—Brief notes are given on tuberculosis in birds, dogs, cats, pigs, horses, and cattle. As a result of the investigations already made on methods of controlling the disease the author believes that healthy animals may be protected by the Bang method or by the vaccination method recently perfected by Calmette, Guerin, and Vallée.

Immunization to tuberculosis, P. HAAN (*Rev. Gén. Méd. Vét.*, 8 (1906), No. 91, pp. 349-356).—The author reviews in a critical manner the various schemes which have been proposed for the immunization of cattle and other animals toward tuberculosis. It is admitted that much promise is given by the results thus far obtained but that at present we are still in need of a method which will give certain results in combating the disease.

Cornstalk disease, R. A. CRAIG (*Indiana Sta. Circ.*, 3, pp. 10).—A disease which was referred to by this name appeared quite extensively in Indiana during 1902 and 1906. Reports were obtained from a number of observers, some of them veterinarians, concerning the symptoms of the disease and circumstances surrounding outbreaks. Moldy corn was obtained from a field where cattle had developed the disease and was fed to a heifer at the rate of 4 to 5 lbs. twice per day. At the end of 6 days the heifer showed considerable weakness and other pathological symptoms but the weakness disappeared the following day and the appetite remained good during a period of 16 days.

The theories held by different observers regarding the cause of cornstalk disease are briefly summarized. The conclusion is reached that there are probably several diseases referred to under the same name. While the symptoms resemble those of toxic poisoning it is by no means certain that

potassium nitrate in the corn is the cause of the trouble. It is suggested that prussic acid may at times be developed in corn.

Treatment of milk fever, RABUS (*Wechschr. Tierheilk. u. Viehzucht*, 50 (1906), No. 39, pp. 766-768, fig. 1).—A description is given of a suitable apparatus for use in inflating the udder with filtered air in cases of milk fever. The apparatus is claimed to possess the advantages of simplicity and ease of cleaning.

Ranula inflammatoria in cows, E. WYSSMANN (*Schweiz. Arch. Tierheilk.*, 48 (1906), No. 5, pp. 323-333).—This disease is known under a number of other names, such as inflammatory edema, frog tumor, etc., and attacks the tongue at the base of this organ and also the submaxillary and sublingual glands and connected structures. The usual form of lesion is a tumor or a multilocular cyst.

The author had occasion to study a number of cases of this sort and gives a detailed clinical history of one case. The tumor was painted 3 times daily with a tincture of iodine and chloroform, and potassium iodid was administered internally in an aqueous solution. A septicemic infection spread from the tumor, causing symptoms which resembled those of malignant catarrhal fever, but recovery ultimately took place.

The alterations in the mucous membrane in cases of strongylosis in cattle, J. BLUNSCHEY (*Schweiz. Arch. Tierheilk.*, 48 (1906), No. 5, pp. 291-323, pls. 2, fig. 1).—A careful microscopic study was made of the lesions caused by strongylus in the walls of the fourth stomach and duodenum. Although strongylus is a common parasite of cattle it becomes definitely located only in the stomach and small intestines.

The parasites penetrate into the folds of the stomach walls and the tubes of the glands. After reaching the muscular coat they cause an enlargement of the gland tubes and coil up spirally. In this position they may cause nodules in which a pronounced necrosis of tissue takes place. The healing process is accomplished by the substitution of connective tissue. In the small intestine strongylus attacks mostly the lymph follicles, but in the posterior part of the small intestine a considerable degeneration of the epithelium is observed.

Fatal hemorrhage as a result of a tuberculous ulcer of the fourth stomach, E. PLATE (*Berlin. Tierärztl. Wechschr.*, 1906, No. 39, pp. 713, 714).—A careful post-mortem examination of a case of this sort showed that the lymphatic glands were enlarged and infected with tubercle bacilli and that an ulcer of tuberculous nature had developed so extensively in the wall of the fourth stomach as to cause fatal hemorrhage.

Poisoning from the use of spoiled brewers' grains, SCHILFFARTH (*Wechschr. Tierheilk. u. Viehzucht*, 50 (1906), No. 25, pp. 484, 485).—Three cattle died as the result of eating spoiled brewers' grains. The liver showed fatty degeneration and a grayish yellow color. The mucous membrane of the fourth stomach and intestines was also loosened and somewhat infiltrated. At the same time 4 cows showed mild symptoms of poisoning, but ultimately recovered.

Nodule disease of the intestines of sheep. "Bare-lot" method of raising lambs, W. H. DALRYMPLE (*Louisiana Stas. Bul.* 89, pp. 11, figs. 5).—A further test was made of the method already proposed by the Louisiana Station for the control of nodular disease in lambs (E. S. R., 17, p. 405). The results obtained in the second test indicate that lambs may be successfully raised on bare lots from ewes badly infested with the nodule worm. The bare-lot method seems not to prevent entirely the infestation with stomach worms.

Epizootic gangrenous mammitis in ewes, DETROYE (*Bul. Soc. Cent. Méd. Vét.*, 83 (1906), No. 18, pp. 452-457).—An outbreak of this disease of great virulence occurred and spread with unusual rapidity. An experiment was made

in injecting a 2 per cent solution of carbolic acid into the affected parts of the udder. The immediate result of repeated injections of this sort was to check the progress of the disease and apparently to destroy the micro-organism, but the tissue of the udder sloughed off as a result of the previous infection and treatment. This method may be of value in preventing the spread of the infection, but in curing the disease the author recommends the surgical method of the removal of all affected tissue.

A disease of the pig due to Spirochæta, S. DODD (*Jour. Compar. Path. and Ther.*, 19 (1906), No. 3, pp. 216-222, pl. 1, fig. 1).—Several species of this genus are known to be pathogenic for animals, but the one observed by the author was not found in the blood circulation but in skin lesions over the surface of the body. A post-mortem examination of affected pigs showed almost no characteristic pathological conditions outside of the skin lesions except anemia. Inoculation experiments with the blood of affected hogs showed that the parasite was not present in the blood. It was found that the disease was readily transmitted by contact.

Pseudoleukemia in pigs, ROTTKE (*Berlin. Tierärztl. Wchnschr.*, 1906, No. 59, pp. 712, 713).—In cases of this disease the bronchial and mediastinal glands are greatly swollen and all of the lymphatic glands show a yellowish-white color. The musculature appears pale and the liver and spleen are somewhat enlarged. The author believes that some cases of pseudoleukemia will prove to be of a tuberculous nature.

Rachitis accompanied with spasms in pigs, FROMBERG (*Maanedskr. Dyr-læger*, 18 (1906), No. 6, p. 255).—In treating cases of rachitis in pigs complicated with symptoms of cramps, the author obtained satisfactory results from pumping air directly into the abdominal cavity by means of the ordinary apparatus to be used in the treatment of milk fever. The abdominal cavity was distended by pumping in air for a period of 7 to 20 minutes.

Susceptibility of ruminants and apes to the trypanosome of dourine, F. MESNIL and J. ROUGET (*Ann. Inst. Pasteur*, 20 (1906), No. 9, pp. 689-697).—It has generally been considered that ruminants and apes are not susceptible to dourine. In order to test this matter the authors undertook a number of inoculation experiments in which it appeared that cattle, goats, and apes may be infected with the trypanosome of dourine in the same manner as with other trypanosomes which are pathogenic for mammals.

The diagnosis of rabies, FORGEOT and NICOLAS (*Ann. Soc. Agr. Sci. et Indus. Lyon*, 1905, pp. 390-404, figs. 8).—The anatomical changes in the nervous system in cases of rabies are described with particular reference to Negri's corpuscles, which bodies were carefully studied by the authors.

The conclusion is reached that when Negri's corpuscles are found in Ammon's horn a positive diagnosis of rabies can be safely announced. The authors were unable to find Negri's corpuscles except in actual cases of rabies. This method of diagnosis suffers from certain disadvantages since the detection of Negri's corpuscles is a rather difficult one, and the process occupies considerable time and necessitates many complicated histological manipulations and the use of a high magnification. The results obtained in most instances, however, are sufficient recompense for the time employed.

The elevation of the body temperature through the treatment of rabies and infectious diseases, P. REMLINGER (*Compt. Rend. Soc. Biol. [Paris]*, 60 (1906), No. 22, pp. 1030, 1031).—Rabies virus is well known as being very susceptible to the action of heat. The author suggests that this fact may be naturally connected with the rarity of rabies in birds on account of their high normal temperature and the infrequency of disease in the Tropics.

An attempt was made to determine the effect of heat in the treatment of

rabies. Animals were subjected to a high temperature and the internal temperature was raised by treatment with pilocarpin and other drugs, but no effect was observed on the progress of the disease.

Treatment of rabies by means of radium rays and the mechanism of their action, III, G. TIZZONI and A. BONGIOVANNI (*Centbl. Bakt. [etc.]*, 1. *Abt.*, *Orig.*, 42 (1906), No. 2, pp. 161-170).—Among the 3 different kinds of radium rays with which the authors experimented in the treatment of rabies it was found that the kind which most closely resembles kathode rays is most effective, the other 2 being entirely without effect or merely assisting the action of the kind first named.

In the case of common laboratory animals it appears that by means of these rays a cure may be brought about provided the treatment is applied within 2 to 5 days after inoculation. The treatment must be continued 18 hours if postponed for 3½ days after inoculation, while less than one-half as much time is required if given immediately after inoculation.

The action of radium on rabies virus, G. TIZZONI and A. BONGIOVANNI (*Ann. Inst. Pasteur*, 20 (1906), No. 8, pp. 682-688).—This is a controversial article in which the authors reply to criticisms raised against their previous announcement regarding the effect of radium on rabies virus. A repetition of experiments planned in a manner similar to those carried out gave results which indicate that rabies in rabbits may be cured by the application of radium rays. The authors suggest the possibility of using radium in the same way in treating rabies in man.

The transference of rabies virus to frogs, J. VON LÖTTE (*Centbl. Bakt. [etc.]*, 1. *Abt.*, *Orig.*, 42 (1906), No. 1, pp. 25-29).—The literature of rabies contains few references to the possible transference of rabies virus to frogs. The author, therefore, undertook a number of experiments in which *Rana esculenta* and *R. temporaria* were inoculated with the virus of rabies. It was found possible to transfer the virus to frogs and after one or more transfers from frog to frog to inoculate warm-blooded animals with material thus obtained. The course of the disease produced by such material was, however, somewhat checked and it appeared that the virus was slightly attenuated as the result of inoculation in frogs.

A study of the so-called infectious lymphosarcoma of dogs, S. P. BEEBE and J. EWING (*Jour. Med. Research*, 15 (1906), No. 2, pp. 209-227, pls. 3).—This venereal disease of dogs is known in various countries in Europe and many cases have appeared in New York. The character of the tumors was carefully studied by the authors and it appears that the disease may be transmitted by the tumor cells. The active agent in the transmission of the disease or in the production of infection is not known.

Membranous angina of a pseudo-diphtheritic nature in dogs, V. BALL (*Jour. Méd. Vét. et Zootech.*, 57 (1906), Aug., pp. 449-456, fig. 1).—The bacillus of human diphtheria may be transmitted by inoculation to a number of animals and birds, but the disease studied by the author and reported in the present article was of a pseudo-diphtheritic character. The symptoms were general debility, lack of appetite, and thirst. A persistent cough was present and the animal ultimately became unable to swallow. The disease may be complicated with hemorrhages and albuminuria, particularly if a general infection follows.

The treatment recommended consists in the application of local antiseptics such as salicylic acid, methylene blue, and carbolic acid, and the administration of tonics.

A new treatment of demodectic mange of dogs, L. DUPAS (*Bul. Soc. Cent. Méd. Vét.*, 83 (1906), No. 18, pp. 457-465).—A great variety of remedies have

been recommended in the treatment of mange in dogs. In the author's experiments alcohol was tested for this purpose. The treatment consisted in thorough cleansing of the skin, after which alcohol was rubbed on the affected parts. The solution used in these experiments was obtained by adding 2 parts of 95 per cent alcohol to 100 parts of water. This treatment is not successful in all cases, but gives very satisfactory and certain results in cases of mange which have not been neglected too long.

The virus of fowl plague, K. LANDSTEINER (*Centbl. Bakt. [etc.], 1. Abt., Ref., 38 (1906), No. 17-18, pp. 540-542*).—The author was unable to determine whether the virus of fowl plague is found inside the blood corpuscles or merely upon the outside surface. The virus may be separated by the use of the centrifuge with the aid of a 1 per cent salt solution. In order to obtain evidence which will help in determining whether the organism is protozoan or bacterial, the author subjected the virus to a 0.5 per cent solution of saponin in a 1 per cent salt solution. This solution quickly destroyed the trypanosomes, but did not affect ordinary bacteria or yeasts. Birds inoculated with virus treated with the solution remained alive, while control fowls inoculated with untreated virus died within 64 to 78 hours.

Immunization against fowl cholera with aggressins and bacterial suspensions, O. HUNTEMÜLLER (*Centbl. Bakt. [etc.], 1. Abt., Orig., 42 (1906), No. 2, pp. 170-174*).—Previous investigations have shown that in the bodies of animals dying of certain infectious diseases an aggressin was found which had the effect of increasing the virulence of small doses of the pathogenic organism and of producing an immunity when animals were treated with it for a considerable length of time. An exudate obtained in this way from guinea pigs inoculated with fowl cholera did not cause an increase in the virulence of the organism. An immunity was brought about, however, by treating the animal with the pathogenic organisms after they had been killed by subjection to a temperature of 44° C. The active principle in suspensions thus obtained was found to be connected with the bacterial bodies since, when these suspensions were filtered, the material free from bacteria had no effect.

Chicken pox or sore head in poultry, C. A. CARY (*Alabama College Sta. Bul. 136, pp. 17-56, pls. 3*).—Chicken pox is said to cause more mortality among chickens in Alabama than any other disease. There appears to be no well-marked distinction between chicken pox, avian diphtheria, and roup, as these terms are ordinarily used. The literature relating to the subject is carefully reviewed. A number of inoculation tests were made with organisms obtained from cases of chicken pox.

The author concludes that the cause of the disease is not definitely known. Some evidence is usually presented to show that *Bacillus cucosmus* or some species of *Bacterium* or *Pseudomonas* may be factors in causing the disease, but careful experiments failed to connect either one of them with the disease as the primary cause. Chicken pox may be carried by various insects. The period of incubation varies from 2 to 20 days. Chicks from 7 to 8 months of age are most susceptible, and affected birds may recover in from 2 to 8 weeks. Mortality varies from 50 to 70 per cent.

The author reports satisfactory results from the application of iodoform and tannic or boric acid upon affected parts of the throat and eyes. A large number of other antiseptics have been used with fair success. A bibliography of the subject is given and mention is made of the chief points to be observed in the sanitary management of fowls.

A remedy for gapes in fowls (*Jour. Bd. Agr. [London], 13 (1906), No. 6, p. 368*).—Success is reported in treating gapes by the fumes of carbolic acid. In

using this remedy the chicks to be treated may be placed in a basket over a pail containing carbolic acid in which a hot brick is placed for the purpose of volatilizing the acid.

Contagious epithelioma of fowls, E. BURNET (*Ann. Inst. Pasteur*, 29 (1906), No. 9, pp. 742-765).—According to the author's observations there is no necessity of supposing an intermediate host, such as flies, fleas, and other parasites for the micro-organism of contagious epithelioma in birds. The cellular inclusions observed in cases of this disease and frequently described as parasites do not pass through filters and therefore can not be considered as the true cause of the disease, since filtered virus is infectious. By the use of an attenuated virus a slight immunity to the disease may be produced.

Spirochæta in chickens, S. VON PROWAZEK (*Arch. K. Gesundheitsl.*, 23 (1906), No. 2, pp. 554-569, pls. 2).—The spirochæta which most commonly affects fowls, causing spirillosis, appears in the blood within 2 days after inoculation and is most numerous on the fourth or fifth day. The spleen becomes enlarged and violet-red in color and the liver shows necrotic areas. An organism of this group is described as new under the name *Spirochæta anodontæ*.

Poultry parasites, C. M. G. JOHNSTON (*Orange River Colony Dept. Agr. Bul.* 12, pp. 15, figs. 5).—Brief accounts are given of fowl tick, fowl mite, scaly legs, gape worm, and roup. These appear to be the most serious fowl diseases in Orange River Colony, and brief directions are given for their effective treatment.

An epizootic outbreak of tapeworms in pheasants, U. CAPARINI (*Clin. Vet. [Milan]*, 29 (1906), No. 36, pp. 872-877).—In a serious infestation of pheasants with tapeworms the author found that the trouble was due to one species of tapeworm which assumes a number of forms quite different in appearance. The biology and morphology of this tapeworm was studied, but no practical suggestions were made regarding the control of the disease.

RURAL ENGINEERING.

Contributions to the knowledge of irrigation in the United States of America, KRÜGER (*Arch. Deut. Landw. Gesell.*, 1906, No. 119, pp. 60+7, pls. 21, figs. 27).—This report is the result of a tour of investigation made by Engineer Krüger through the United States in 1904 for the purpose of studying irrigation conditions and methods in the arid West. The itinerary included Colorado, Utah, Nevada, California, Arizona, and New Mexico. Particular attention was given to the construction of canals and reservoirs, in which it is reported that little of novelty, aside from the temporary and unsubstantial character of the work, is to be seen.

From his studies the writer concludes that little can be learned by the German agriculturist from American irrigation methods, because of differences in climatic and economic conditions as well as the fact that German irrigation is for the purpose of supplying the soil with fertilizing ingredients rather than moisture. The writer also thinks it would be quite unwise to build structures in a country as thickly populated as Germany of such insecure and flimsy construction as are found in the western United States. For the German colonies, however, where arid conditions exist and where the population is relatively thin, the writer considers that the application of improved western practices and institutions would be eminently advisable. He recommends the enactment of a law for these colonies similar in operation to our reclamation law, a fund being provided by the government for the construction of irrigation works, the

cost of which would be returned to the government by those settling upon the tracts reclaimed.

Official proceedings of the Fourteenth National Irrigation Congress, held at Boise, Idaho, September 3-8, 1906 (*Proc. Nat. Irrig. Cong.*, 14 (1906), pp. 280, pls. 40).—A report of the proceedings of the congress held at Boise, Idaho, Sept. 3-8, 1906, containing the various papers presented, the discussions upon the same, and the resolutions passed.

Closing the break of the Colorado River into the Salton Sink, southern California, H. T. Cory (*Engin. News*, 56 (1906), No. 26, pp. 671-674, figs. 3).—The author reviews the causes leading to the original break and describes the several unsuccessful attempts which have since been made to close the crevasse in the river bank and thus prevent the inundation of a large body of irrigable land in Imperial Valley. Unless the crevasse can be closed at once the course of the river will be permanently altered, and a greater geographical change will occur than has ever before been effected by human agency.

Raising of water by compressed air at Preesall, Lancashire (*Engin. Rec.*, 54 (1906), No. 9, pp. 243-245).—In this article, transcribed from a paper written by James Kelly and published by the Institution of Civil Engineers, some experiments are described in the operation of air lifts. The water-bearing strata were found at a depth of 80 to 100 ft. below the surface. The compressed-air system was adopted, owing to the low yield from any one well and the necessity, therefore, of raising water over a considerable area, together with the desirability of having a system which would present a minimum possibility of breakdown—an important consideration in view of the appreciable amount of sand in the water, which speedily ruined the valves and working parts of a mechanical lift originally used.

Several conclusions were deduced from the experiments, as follows:

(1) That it was futile to attempt to force the output of a well, the best efficiency being obtained at comparatively low rates of working.

(2) The volume of free air used per cubic foot of water raised varied between 3 and 12 cu. ft., the lesser volumes being for the lower rates of working.

(3) The efficiency based upon the ratio of work done in raising water to the indicated work of the air cylinders varies between 20 and 40 per cent, being dependent upon the ratio of depth of submersion of the air pipe to the height of delivery (a ratio of 1.5 to 1 being the best), as well as upon the relative size of air pipe and well tube, and upon the rate of working, the lower rates of working giving the higher efficiency.

(4) The best results were attained by keeping the velocity of air and water combined at about 12 ft. per second at the point of entrance to the delivery pipe.

(5) The size of the delivery pipe should gradually increase in diameter from the bottom of the well to the surface.

Brief notes on absorption losses on canals, etc., [R. G. KENNEDY] (*Proc. Irrig. Conf., Simla, 1904*, I, pp. 57, 58).—The writer prefers to express absorption losses as so many cubic feet per second per million square feet of surface area of water, since it is claimed that it is a needless requirement to take wetted perimeters instead of surface because, while seepage varies as the former, evaporation which is included in all such data varies as the latter and the depth enters into the equation in an unknown degree.

Absorption losses on canals.

Particulars.		Loss in cusecs per million square feet of water surface.		
		Minimum.	Maximum.	Average.
<i>On Bari Doab Canal—Good soil generally.</i>				
Main line	Discharge about 4,000 cusecs, depth about 6 ft., all in shingle and sandy soil.			9.7
Branches	Discharges from 1,000 to 3,000 cusecs, soil good loam not sandy, with silted berms, but no fine silt on bed.			2.2
Distributaries ...	Discharges 30 to 100 cusecs, good loam soil, silted side berms and in lower reaches, fine silt on bed.	2.3	4.4	3.3
Water courses ...	Discharges 0.50 to 3.0 cusecs, good loam soil, generally rough bed and banks, in all sorts of conditions, some new.	3.3	30.0	9.4
On fields.....	When first water is laid on, sometimes soil was moist and in some cases quite dry.	5.5	16.0	8.0
<i>On Sirhind Canal—Sandy soil generally.</i>				
Main line..... (First 26 miles.)	Discharge about 4,000 cusecs, depth about 7 ft., all in sandy soil, no shingle, sand, silted bed, and no side berms. The subsoil water table was close to surface and sloping away to the river from the canal at a grade of 2.4 ft. in 1,000.			9.0
Branches	Discharges from 2,000 to 4,000 cusecs, depth about 7 ft., all sandy soil, little or no side berms, and sand on bed.			5.2
Distributaries ...	Discharges 30 to 100 cusecs, all sandy soil, in all sorts of conditions as to bed and berms.	(5.0)	(12.0)	(8.0)
Water courses ...	Discharges 0.50 to 3.0 cusecs, all sandy soil in all sorts of repair.	(7.0)	(60.0)	(22.0)
On fields.....	When water is first laid on	(12.0)	40.0	(21.0)

Earthen dams. [A. HILL] ([*Proc. Irrig. Conf., Simla, 1904*], I, pp. 59-62).—Considerable information is given relating to the subject in general, and certain opinions drawn from the experience of the writer are given in the following notes:

“The cross section of the bank should be proportionate to the depth of water, and the slope from the point where the full supply level touches the bank to the outer toe should be not less than 4 to 1 for banks of ordinary construction in less than 40 ft. depth of water. This line is the hydraulic gradient for the bank.

“The earth in the bank will become saturated in time, and in high banks the lower part will move and slip under the pressure of the upper portion and water, unless held down by some material not affected by water.

“For depths of water greater than 40 ft. the behavior of the bank when saturated is uncertain, and the cross section must be greater than for a bank of less depth.

“Up to 40 ft. depth the section recommended by the author has a core of selected water-tight earth 10 ft. wide at highest flood level, and with side slopes $1\frac{1}{2}$ to 1 on both sides. This core is to be protected on the top and water side by material not likely to slip when wet, like the soft moorum of decomposed rock of the Deccan, and the slope on the water face may be $2\frac{1}{2}$ to 1 or 3 to 1.

“The water-tight core should be covered on the rear slope by a mass of material not affected by water, and, to keep the earth from being forced into the drainage material, it should be arranged like a filter, with soft moorum on the inside against the earth core and large coarse material on the outer side, broken metal or screened gravel being very suitable for the outside.

“At the rear toe provision must be made for the water to escape, and the toe must be a mass of dry stone when the foundations are good.

“The best foundation for the rear toe of a bank is porous rock like moorum,

or rock, and the whole of the rear mass of drainage should be carried down to such rock when it is within reasonable depth.

"When no such moorum or rock is available then the site is not desirable, but if a bank has to be built a large trench should be excavated beneath the rear toe and filled with good drainage material and a berm formed over it.

"If a masonry core wall be used in an earthen dam it must be supported by earth backing to enable it to resist the thrust of the saturated material on the upstream side of the wall.

"If the cross sections of all sorts of embankments be studied, from that of a small watercourse up to a small flank embankment with 40 ft. depth of water, it will be found that in all cases where the bank is thoroughly satisfactory the hydraulic gradient through the bank is not less than 4 to 1; the hydraulic gradient is the slope from the point where the water touches the bank to the rear toe, and is the maximum gradient available for driving the water through the bank."

Land drainage, A. R. WHITSON and E. R. JONES (*Wisconsin Sta. Bul. 138, pp. 40, figs. 15*).—The authors include a compilation of data sufficient to enable the design of an open ditch or tile drainage system, and describe in detail several examples of the successful application of drainage in Wisconsin, citing the benefits which have accrued in each case. The practical operations necessary in the construction of tile drains are discussed, and various details of construction are described and illustrated. A brief synopsis of the Wisconsin drainage laws is followed by a discussion of the distribution of benefits, and the bulletin is concluded by an appendix on the description and use of instruments used in making drainage surveys.

The best value of Kutter's "N" to adopt in canal design, [R. G. KENNEDY] (*[Proc.] Irrig. Conf., Simla, 1904, I, p. 175*).—In discussing the question the author admits that the values of N worked out from time to time from observed canal discharges vary greatly for the same channel and even for the same site. Sufficient observations have, however, been made to fix N for Indian canals within fairly narrow limits. "On a quite new and well-dressed channel N goes down to 0.020, but with the bed silted and the banks fairly well kept, N is fairly steady at 0.0225 and ought to be adopted as an all-round figure in canal design."

In the discussions on this subject at the same conference the consensus of opinion seemed to be "that for distributaries or not very large canals, 0.0225 is the right value to assume, and for very large canals, 0.020 may safely be taken." One instance was cited where with a discharge of 1,200 to 1,500 cu. ft. per second the coefficient was found to be 0.016 to 0.017; in another case where the bed width was 250 ft., the depth 9.5 ft., and the discharge 8,320 cu. ft. per second the coefficient was found to be 0.018.

Industrial alcohol: Sources and manufacture, H. W. WILEY (*U. S. Dept. Agr., Farmers' Bul. 268, pp. 45, figs. 10*).—This bulletin is prepared in response to the general demand for information on the manufacture and use of industrial alcohol. The law under which this product may be manufactured occupies the first few pages of the bulletin, after which some extracts are given from the rulings of the Commissioner of Internal Revenue relative to the restrictions surrounding the production of denatured alcohol.

The substances used in its manufacture and denaturation are named and discussed. In this connection the suitability of several plants, such as artichokes, bananas, barley, cassava, potatoes, rice, speltz, and sweet potatoes for use in alcohol production are considered in some detail, tables being given of the usual starch or fermentable content of each. The comparative value of potatoes and other root crops for making alcohol is shown by the following

table, in which is given the percentage by weight of fermentable matter contained in each plant:

	Per cent.
White turnips	6 to 8
Rutabagas	8 to 13
Mangel-wurzels	8 to 15
Carrots	8 to 16
Parsnips	8 to 17
Sugar beets	10 to 22
Potatoes, sweet potatoes, and yams	14 to 26

The subject of the use of waste material or by-products receives attention, in which connection the possible value of cornstalks, molasses, wood pulp, sawdust, cannery wastes, etc., is considered. The manufacture of alcohol from such materials is not in general considered profitable, due to the fact that with some materials the season of supply would be too short, while in other cases the amount of alcohol obtainable is so small as to make production unprofitable unless the waste material could be utilized in distilleries already established.

The processes involved in the manufacture of alcohol are described and the apparatus illustrated, the bulletin being closed by conclusions in which the author draws attention to the fact that under the revenue regulations "the farmer must be content with producing raw materials and that he can not look forward to becoming a practical distiller."

It is further stated that "of the raw materials which can be utilized for the manufacture of alcohol, Indian corn is by far the most abundant and most promising source at the present time. The average price of potatoes must be very much decreased before raw material of this kind can come into competition with Indian corn as a source of alcohol." The benefits of the new law are stated to have probably been overestimated by the people at large, and it is suggested that it may be some time before the use of industrial alcohol in this country reaches the figure already attained by European countries.

Industrial alcohol: Uses and statistics, H. W. WILEY (*U. S. Dept. Agr., Farmers' Bul.* 269, pp. 29, figs. 10).—This bulletin supplements Farmers' Bulletin 268, and takes up largely the question of the utilization of denatured alcohol. Alcohol stoves and lamps are briefly described, with illustrations, and some information is given on the use of the alcohol motor.

The uses of denatured alcohol not directly entering into farm operations are enumerated and briefly discussed. Among these uses are included the manufacture of coal-tar dyes, smokeless powder, varnishes, ether, pharmaceutical preparations, imitation silk, artificial vinegar, and flavoring extracts.

The bulletin is concluded by tables giving statistics which show the magnitude of the distillery industry in each of the several States of the United States, together with some information on the consumption of alcohol and on the denaturing ingredients used in European countries.

Modern conveniences for the farm home, ELMINA T. WILSON (*U. S. Dept. Agr., Farmers' Bul.* 270, pp. 48, figs. 26).—The object of this bulletin is to suggest means and methods by which the household labor, now a hardship on many farms, may be lightened and the comforts, conveniences, and sanitary cleanliness of city life may be introduced into rural communities.

The question of water supply is first taken up and some suggestions are given for the proper location of wells, together with the methods of storing water by cisterns, elevated and pneumatic tanks, and the use of hydraulic rams, windmills, and gas or hot-air engines for the development of the water supply.

The house itself is next considered, hints being given on its proper location and on the building of the foundation and cellar. The arrangement of the

plumbing and the various kitchen and bathroom fixtures is explained in detail. Sewage disposal receives attention, various methods of collecting and disposing of liquid and solid wastes being described and illustrated. The heating system of the house is described with special reference to the use of the hot-air furnace and the size and location of air-distributing pipes. Following this are cited several examples of homes where modern conveniences have been installed, the character and cost of the improvements being noted and plans given of typical houses and grounds and of the water and sewerage systems.

RURAL ECONOMICS.

The cost of producing farm products, W. M. HAYS and E. C. PARKER (*U. S. Dept. Agr., Bur. Statist. Bul. 48, pp. 90, pls. 4, figs. 11; Minnesota Sta. Bul. 97, pp. 90, pls. 4, figs. 11*).—These bulletins report the results of investigations by the Bureau of Statistics, in cooperation with the division of agriculture of the Minnesota Agricultural Experiment Station, relating to the cost of producing farm products and giving methods devised in successfully inaugurating these studies.

Several farms in 3 counties of the State, where diversified and grain farming is conducted, were selected for the purpose of this inquiry, and detailed statistical data bearing upon every phase of the cost of producing crops are reported for the years 1902, 1903, and 1904. The objects sought relate in general not only to the economic side of the agricultural industry, such as securing profitable returns for labor, invested capital, managing ability, etc., but to the broader problems of farm management and organization, of providing practical data for use in agricultural schools and colleges, and of "developing a literature on farm management and a class of effective teachers, editors, and general writers."

In commenting on the value of the data secured in this investigation to the future welfare of agriculture, the authors conclude as follows:

"Statistics on the cost of production and concerning the general business of the farm, gathered under the methods here employed, together with data from plat experiments with crop rotations, from plat and laboratory experiments with fertilizers, from physical studies of the soil, and from the general practical experiences of proficient farm managers must be secured and made the common knowledge of our farmers if the farms of the United States are to be so planned and reorganized as to yield profits commensurate with the rapid appreciation of land values that is bound to follow the increase of population and wealth in the United States."

Condition of farm labor in California, W. V. STAFFORD and J. M. ESILLEXMAN (*Bien. Rpt. Bur. Labor Statist. Cal., 12 (1905-6), pp. 72-81*).—Data secured by direct inquiry and by correspondence regarding the conditions of farm life and the wages of farm labor in California are reported.

Attention is called to the scarcity of reliable farm help, and the investigations center around the question as to whether or not the home life of farm laborers and the wages paid have any bearing on the problem of the scarcity of labor. The statistics presented relate to the classes of farms, number of white and oriental laborers, the conditions surrounding their home life, and the wages paid both with and without board, house rent, etc. Regarding the question under investigation the following conclusion is drawn:

"It is believed that this investigation shows conclusively the actual conditions prevailing in ranch work. The constant complaint, heard from every section of the State, of the scarcity of farm laborers, plainly indicates the necessity of some radical change in our present system. The encouragement of permanent

employees with families, to whom houses are furnished free, and the providing of baths, well-cared-for bunk houses, and improved table fare will certainly do much toward solving this problem, especially where the tendency is to cut up the large holdings."

The land system of New Zealand, S. P. SMITH (*New Zeal. Off. Yearbook 1906*, pp. 551-564).—The distinguishing features of the present land system in New Zealand are discussed in this article, which includes notes on the acquisition of native lands by the government, the conditions under which the land is allotted to settlers, and the systems of land tenure.

The land system of New Zealand rests on "the principle of State ownership of the soil, with a perpetual tenancy in the occupier. A very large proportion of the crown lands are now disposed of for 999 years. The rentals are based on the assessed value of the land at the time of disposal, without increase or recurring valuations. Under this system there is a fixity of tenure practically equal to freehold, and which, like freehold, necessarily carries with it the power of sale, sub-lease, mortgage, or disposition by will. At the same time the improvements made in the soil by cultivation, etc., are secured to the tenant should he from any cause be obliged to forfeit or surrender his lease."

Three modes of land tenure are recognized: (1) By purchase, in which one-fifth of the price is paid down at once and the remainder within 30 days, the final title not being given until specified improvements are made; (2) lease with a purchasing clause, at a 5-per-cent rental on the value of the land, the lease being for 25 years and carrying the right to purchase or to convert into a lease in perpetuity; and (3) "lease in perpetuity at a rental of 4 per cent on the capital value."

A digest of the land laws of New Zealand embracing the administration, classification, mode of acquisition and selection, improvement, and settlement of crown lands is included in the article.

Advances to settlers, S. P. SMITH (*New Zeal. Off. Yearbook 1906*, pp. 564-573).—This article treats of the plan adopted in 1894 by the New Zealand government "to afford relief to a numerous class of colonists who were struggling under the burden of high rates of interest and heavy legal expenses of mortgaging, etc." The plan consists in advancing sums of money ranging from £25 to £3,000, with interest "at the rate of 5 per cent, reducible to 4½ per cent provided payment is made not later than 11 days after due date and no arrears remaining outstanding." The successful working of the plan from its inception to the present time is shown by means of statistical data which are reported and discussed.

The indebtedness of peasant proprietors in Bavaria, A. COHEN (*Die Verschuldung des bäuerlichen Grundbesitzes in Bayern*, Leipzig: Duncker & Humblot, 1906, pp. XIX+470).—This volume is a contribution to the history of the development of agricultural credit in Bavaria, and treats particularly of the period between 1598 and 1745. The development of land ownership by the different classes of proprietors is described, the methods of transferring property are outlined, and the different forms of agricultural indebtedness are discussed in detail from the legal, social, and economic points of view.

Manual of world economics, edited by E. VON HALE (*Die Weltwirtschaft, ein Jahr- und Lesebuch*, Leipzig and Berlin: B. G. Teubner, 1906, pts. 1, pp. VIII+366; 2, pp. VI+253; 3, pp. VI+281).—Part 1 of this publication contains an article on Agricultural Production by Wygodzinski, which gives statistics on the world's production of cereals and other staple crops, live stock, and sugar for 1905 and 1906, in comparison with preceding years. Statistics are also presented on the exports and imports of cereals for the years 1904 and 1905.

Part 2 contains an article on The Condition of Agriculture in Germany by U. Ballod, which gives statistics on cereal and crop production for the years 1896 to 1906, and discusses other economic topics of an agricultural nature as the indebtedness of farmers, land transfers, agricultural organizations, etc., in Germany.

Part 3 gives general economic and agricultural statistics for 1904 and 1905 of the other countries of Europe, of Japan and China, the United States, and several countries in South America.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter*, 8 (1906), No. 8, pp. 57-64; *Sup.*, pp. 65-72).—The December number contains in addition to the usual statistics on the condition of crops in the United States and foreign countries the following special articles: Ocean and inland rates on grain, December, 1906; agricultural products of Mexico; general hop situation; world's international trade in coffee; the grain shortage in Russia; the beet-sugar production of Europe; and other matters relating to agriculture. The supplement contains, in addition to the annual report of the Bureau of Statistics for the fiscal year 1905-6, special articles on stocks of American cheese, October 31, 1906; cotton growing in the German colonies; acreage, production, and value of the principal farm crops of the United States in 1906; cotton growing in British Central Africa, etc.

Agriculture in New Zealand, M. MURPHY (*New Zeal. Off. Yearbook 1906*, pp. 374-386, 590-611).—Statistical data on the acreage and yields of the principal cereal crops, root crops, grasses, etc., for the years 1905 and 1906, in comparison with preceding years, are reported and discussed.

In a special article the author describes the climate and agricultural advantages of New Zealand, shows the extent of land occupancy and the amount of public land still available for settlement, and reviews the outlook for farming in the cultivation of staple crops and the live-stock industry under New Zealand conditions. The prospects for the small farmer are said to be exceptional, owing to the humid climate and fertile soil of the country.

Martinique and Guadalupe, E. LÉGIER (*La Martinique et La Guadeloupe*, Paris: A. Challamel, 1905, pp. 1-190, map 1).—Chapters are devoted to the geography, geology, climatology, and flora of Martinique and Guadalupe, the prevailing economic conditions, together with legislation relating to the sugar industry, the culture, transportation, and sale of sugar cane and its profits, the production of sugar and its returns, the sugar factories, the production of rum and its costs and profits, the various crops of secondary importance grown in the islands, the future of the sugar industry, and to agricultural statistics.

Agricultural statistics, 1906 (*Bd. Agr. and Fisheries [London], Agr. Statis.*, 1906, pp. 89).—This publication contains the returns of acreage under crops, grass, and fallow, and the number of live stock in each county of Great Britain for the year ended June 4, 1906.

AGRICULTURAL EDUCATION.

Federal legislation, regulations, and rulings affecting agricultural colleges and experiment stations (*U. S. Dept. Agr., Office Expt. Stas. Circ.* 68, pp. 21).—This circular includes the land-grant act of 1862, the act of 1866 extending the time within which agricultural colleges may be established, the Hatch Act of 1887, the Morrill Act of 1890, the Adams Act of 1906, excerpts from the act making appropriations for the U. S. Department of Agriculture for 1907, and regulations and rulings of the Post-Office Department, Treasury Department, and this Department concerning these various acts.

A four-year college course in agriculture (*U. S. Dept. Agr., Office Expt. Stas. Circ. 69, pp. 36*).—This is a summary of those reports of the committee on methods of teaching agriculture of the Association of American Agricultural Colleges and Experiment Stations which relate to college courses in agriculture. The circular includes syllabi of courses in agronomy, zootechny, agrotechny, rural engineering, and rural economies, and a discussion of the relation of natural sciences to agriculture in a four-year college course.

The advancement of agricultural education, E. J. WICKSON (*California Sta. Circ. 21, pp. 8*).

Benefits of agricultural education, E. A. BURNETT (*Ann. Rpt. Nebr. Bd. Agr., 1905, pp. 304-308*).—This is an estimate of the benefits to be derived from agricultural education based on present as compared with past conditions of the farmer. Among the factors considered are world-wide competition in agricultural products resulting from better transportation facilities, a wider knowledge of the relation of science to agriculture, changed methods of production, the demand for fancy products, knowledge of diseases and insect pests, instruction in schools of agriculture, and the social status of the rural class.

Developing the American farm boy, F. H. RANKIN (*Urbana: Univ. Illinois, 1906, pp. 18*).—This is an address given December 7, 1905, before the Northern Illinois Horticultural Society, and is concerned mainly with a discussion of the importance of education for country boys and the kind of education they should have. The function of the country school and of the college of agriculture in relation to the boys on the farm is pointed out, and an outline of the work of the Illinois College of Agriculture is given.

Rural education (*Seventh Conference of the Agricultural Societies of New Zealand, Wellington, 1905, pp. 34-39*).—This is a report of the special conference on rural education held July 19, 1905, in connection with the Seventh Conference of the Agricultural Societies of New Zealand. The Auckland Agricultural Society presented the following resolutions embodying the recommendations of a special committee of that society appointed to consider the organization of rural education in primary schools:

"That to be effective, the training for agricultural pursuits should commence in the primary schools, as it is there that the majority of the future farmers receive their education.

"That one of the first objects to be aimed at should be to provide for the special training of a certain number of teachers for the special work of rural education, by short courses of instruction, and by the appointment of traveling instructors for groups of schools to give object lessons explaining the value of school gardens and nature study, and to help and advise the teachers generally in carrying on instruction on these lines.

"That more should be attempted to bring the tuition in country schools into close relation with the practical work of the farm, so that the subjects taught should be directly connected with the work, surroundings, and after life of the pupils, the teaching being especially directed toward the development of their powers of observation, and toward giving them an insight into the fundamental principles which underlie the science of agriculture.

"That the best solution of the financial problem would be to try in certain centers, where local conditions make it possible, the plan that has already been adopted in Canada and the United States, of concentrating a number of small rural schools into one central school, and of providing free transportation of pupils thereto, thereby economizing finance and teaching power, and promoting greater efficiency of teaching, better classification of pupils, a higher grade of

instruction, the employment of better paid teachers, and a more complete equipment of school buildings."

The resolutions were fully discussed in conference, then unanimously adopted, and a committee appointed to present them to the premier.

Teaching agriculture in the common schools (*Ann. Rpt. Nebr. Bd. Agr., 1905, pp. 30-43*).—This report embodies the replies received by the secretary of the State Board of Agriculture of Nebraska to a circular letter sent to educational institutions in the State making inquiry concerning the nature and extent of instruction in agriculture given to teachers during 1905. Such instruction is given in the State University in a special 6 weeks' summer session for teachers, in the State Normal School at Peru during 18 weeks for all students, in the State Normal School at Kearney, in the Nebraska Normal College at Wayne in 50 recitations and 25 hours of experimental work, in the Fremont College at Fremont, 5 hours a week, in Grand Island College at Grand Island, 5 hours a week, in York College at York, 3 hours a week for one term, in the 5 State junior normal schools at Alliance, Holdrege, McCook, North Platte, and Valentine, and in about 50 high schools of the State which include normal courses in their work.

The report also contains a letter from the State Superintendent of Public Instruction, in which a review of progress made in teaching elementary agriculture in the public schools in 1905 is given. Among the features of this progress have been teachers' reading circle work in agriculture, summer school instruction in agriculture in the State junior normals, and normal training in agriculture in high schools.

School gardening has also received attention and much interest has been aroused by means of county and State corn growing and cooking contests carried on through 2 State organizations known as the Nebraska Boys' Agricultural Association and the Nebraska Girls' Domestic Science Association, as well as through a number of county associations of similar stamp.

The place of nature study, school gardens, and agriculture in our school system, J. R. JEWELL (*Reprint from Pedag. Seminary, 13 (1906), pp. 273-292*).—The writer reviews briefly the progress in the introduction of nature study, school gardens, and agriculture into the public schools of this country, and comments on the importance of this work. He shows that the agricultural colleges have been largely engaged in preparing leaders in agricultural education and research, and that the preparation of an intelligent farm population must be taken up by schools of lower grade. The introduction of agriculture into these schools would, in his opinion, result in pupils remaining in school longer, as they have been done in France and Belgium, and he argues from figures of increased corn production in Iowa, increased income for bacon, butter, and eggs in Denmark, and for butter in Ontario that such instruction would result in material benefit to the farmers. He also argues that with the introduction of nature study, school gardens, and elementary agriculture, a better ethical condition among pupils would attain, as has been shown by reports from police officers and courts in New York, Philadelphia, Cleveland, and Dayton. He thinks that education along these lines would set the tide of population distinctly toward the country, help to solve the labor problem on the farm, and greatly enhance rural social conditions.

Progress of nature study in California, B. M. DAVIS (*Nature-Study Rev., 2 (1906), No. 8, pp. 257-265*).—The early history of the nature-study movement in California is outlined; also the more recent progress and tendencies of this movement and the factors and influences now contributing to the advancement of it. Among the more important of the factors mentioned are Stanford Uni-

versity, the University of California, the 5 State normal schools, and some notable examples of nature-study work and school gardening in the public schools of cities.

MISCELLANEOUS.

Nineteenth Annual Report of Illinois Station, 1906 (*Illinois Sta. Rpt. 1906, pp. 13*).—This contains a list of station publications, a brief statement concerning the principal lines of station work, and a detailed financial statement for the fiscal year ended June 30, 1906.

Nineteenth Annual Report of Indiana Station, 1906 (*Indiana Sta. Rpt. 1906, pp. 62*).—This contains the organization list, a report of the director on the work of the different departments of the station during the year, a list of station publications, notes on changes in the station staff, the text of the Adams' Act, with a brief discussion of it, an enumeration of some of the needs of the station, more or less detailed reports of the heads of departments, and a financial statement for the fiscal year ended June 30, 1906.

Twenty-fifth Annual Report of Ohio Station, 1906 (*Ohio Sta. Bul. 176, pp. XIX*).—This contains an announcement concerning the work of the station, the organization list and report of the board of control, a financial statement for the fiscal year ended June 30, 1906, and a report of the director summarizing the work of the station during the year.

Fifteenth Annual Report of Utah Station, 1904 (*Utah Sta. Rpt. 1904, pp. 26*).—This includes the organization list of the station, a report of the director and departmental reports reviewing the different lines of station work during the year, and a financial statement for the fiscal year ending June 30, 1904.

Sixteenth Annual Report of Utah Station, 1905 (*Utah Sta. Rpt. 1905, pp. XXIV*).—This is similar in scope to the above report.

Report of committee on experiment station organization and policy (*U. S. Dept. Agr., Office Expt. Stas. Circ. 71, pp. 7*).—Reference has already been made in this report (*E. S. R., 18, p. 411*).

Publications of the Office of Experiment Stations from its organization to June 30, 1906 (*U. S. Dept. Agr., Office Expt. Stas. Circ. 70, pp. 12*).

Press bulletins (*Ohio Sta. Bul. 176, pp. 400-407*).—Reprints of press bulletins on the following subjects: Wheat midge or "red weevil;" late blight or rot of potatoes; how to fight grasshoppers; fertilizing the wheat crop; profitable farm forestry; beware of impurities in clover and alfalfa seeds; misrepresentations of tree agents; injuries to trees by mice and rabbits; old tobacco plant beds v. new ones, and what is the condition of your seed corn.

A visitors' guide to the more important features of the station's work in 1906 (*Ohio Sta. Circ. 56, pp. 14, figs. 10, map 1*).

Index for Bulletins 48-68 of the North Dakota Station (*North Dakota Sta. Index Buls. 48-68, pp. 13*).

NOTES.

Florida Station.—F. M. Stearns, for two years past gardener, died February 6.

Georgia College and Station.—A series of farmers' institute lectures was given jointly by the college and station along the line of the Georgia Coast and Piedmont Railroad, from February 6 to 10, the railroad providing a special car and bearing all expenses of the trip. Meetings were held at the court-houses and schoolhouses of a number of towns in the southeastern part of the State. The audiences ranged from 60 to 200 at each session. The lecturers were Harvie Jordan, director of farmers' institutes; J. S. Stewart and J. M. Johnson, of the university; R. I. Smith, State entomologist, and C. L. Willoughby, of the station. This is the first movement of the sort in Georgia, but its success is such as to make probable the continuation of the movement.

Cornell University.—The dairy building, which will eventually form one wing of the large agricultural building in course of erection for the college of agriculture, is the first of the group to be completed and is now in use. It consists of a 2-story and basement brick structure, 101 by 51 ft., to be used solely for classroom, office, and laboratory work, and a 1-story and basement wing, 163 by 60 ft., in which are located all the machinery and apparatus for the manufacture of dairy products. In this way the noise, vibration, and dampness incident to butter and cheese making do not interfere with other work.

In the manufacturing rooms much attention has been given to sanitary requirements. Wherever possible brick, cement, iron, and tile have been used instead of wood. To prevent the lodging of dust, door and window frames and baseboards have been set flush with the side walls, and doors have been made smooth and without panels. All shelving is detachable, resting on iron brackets secured by bolts. Side walls are of cement or hard finish, and floors of cement or tile. The latter is used in the butter and cheese making rooms, where special precautions have been taken to secure thorough cleansing and drainage. All rooms are profusely lighted, and the manufacturing rooms are equipped with shades which can be as easily laundered as towels.

Steam for heating and cleansing is obtained from the main agricultural building, and power from a boiler and engine at the extreme end of the wing, to permit of instruction in the management and care of this machinery. Modern appliances have been provided throughout, including a complete outfit for the study of problems in handling market milk, manufacture of Roquefort, Camembert, and other fancy cheeses, dairy mechanics, etc. The main portion of the building contains a museum, reading room, bacteriological and milk-testing laboratories, and all necessary facilities for instruction and research work.

Pennsylvania College and Station.—A four-year undergraduate course in forestry has been established, and Dr. B. E. Fernow has been placed in charge of this work. An assistant professor of forestry is to be appointed, and a new building for the department is projected. Other appointments have been made as follows: Alva Agee, professor of agricultural extension; Charles F. Shaw, instructor in agronomy; Joseph E. Dumipace, assistant in agricultural chemistry, and Ralph Martin, assistant in dairy husbandry.

In the station W. H. McIntire has been appointed assistant in animal nutrition, to succeed N. C. Hammer, who has accepted the position of assistant chemist at the Texas Station. Bailey E. Brown, of the Bureau of Soils, has been appointed assistant professor of experimental agronomy; C. L. Cook and F. R. Reid, of the same bureau, soil experts; J. F. Barron, assistant in experimental agronomy; Arthur W. Broomell and G. C. Given, assistant chemists, and E. F. Fortin, traveling dairy expert.

A soil survey of Center County, in which the station is located, is to be made by the Bureau of Soils.

Rhode Island Station.—W. F. Purrington has resigned as assistant chemist to accept a position in a food laboratory in New Hampshire.

Land-grant Colleges to be made Depositories of Public Documents.—In a supplemental report of the Joint Printing Investigation Commission of the two Houses of Congress it was recommended that the land-grant colleges be designated depositories for all public documents. A bill providing for such distribution was passed by the Congress just closed. This is one of the ends which has been sought by these institutions. Under this measure all Government publications will be sent regularly as issued, instead of requiring special application to Members of Congress, as in most cases at present.

Eulogies on Hon. H. C. Adams.—At a memorial session of the House of Representatives on February 24, tributes to the life and services of Hon. H. C. Adams, of Wisconsin, were paid by his late colleagues. Many appreciative addresses were delivered, which brought out the high regard and the affection in which Mr. Adams was held, his strength in the halls of Congress, and his services in behalf of American agriculture especially.

Referring to the act which bears his name, Representative Esch, of Wisconsin, said: "Realizing the valuable work of the various agricultural experiment stations of the United States, and that with an increase of funds at their disposal this work could be largely increased, he at once introduced a bill with this end in view. Nothing more finely illustrated a distinctive trait of Mr. Adams's character as to fixity of purpose and indomitable will than the patient, courageous, and splendid fight he made for his bill. After the lapse of many weeks and months he won. He deserved to win, and as a result his memory lives in the chief seats of learning of almost every State in the Union."

Representative Lever, of South Carolina, called attention to Mr. Adams's remarkable insight into agricultural problems and his faith in the coming of ideal farm conditions. "It was this enthusiasm, this belief that a good fight for a worthy cause could not fail, which induced him to introduce and fight through Congress a bill doubling the appropriation to the State experiment stations of the country. Who can forget the earnestness, the vigor, the persistency, the tenacity which marked his efforts in this behalf? Nothing could daunt him, nothing could stem the tide of his enthusiasm. The opposition was brushed aside by the justness of his cause and by the eloquence and earnestness with which he presented it, and this one act, this one supreme and triumphant effort in behalf of the American farmer, is sufficient to make Henry C. Adams one of the splendid characters of our history. And when agriculture receives that recognition to which she is entitled, when our farmhouses are filled with educated and happy occupants, and when ideal conditions have been reached, his name will be revered along with that of Morrill and Hatch. Can any higher tribute be paid to any man than to give him equal rank with those men in our history who have wrought most effectively and wisely for the greatest industry of the nation?"

American Breeders' Association.—The third annual meeting of this association was held at Columbus, Ohio, January 15-18, 1907, in conjunction with

meetings of the Ohio State Board of Agriculture and twelve other agricultural organizations of that State. One of the principal features of this meeting was the reports of committees appointed to consider different lines of breeding and to devise ways and means of promoting them. These and the more important addresses and papers presented are noted below.

The association passed resolutions (1) urging upon Congress and the legislatures of the various States a continuation of their liberal policy in the building up of education and research in agriculture, including that relating to the production and improvement of plants and animals; (2) requesting Congress to devote the money now appropriated for the free distribution of seeds to the importation and improvement of plants; (3) requesting such modifications of the game laws of the different States as will permit the capture and shipment of game birds for purposes of propagation; (4) authorizing the committee on eugenics to organize as a committee of the association or as an independent society, and (5) directing the secretary of the association to ascertain the desirability of increasing the annual dues from \$1 to \$2, and the feasibility of publishing a monthly journal devoted to the interests and objects of the association.

Francis Galton, of England, was elected an honorary member of the association. The retiring officers were reelected with the exception of the secretary of the animal section, which office will be filled during the coming year by C. B. Davenport, of Cold Spring Harbor, N. Y. Preference was expressed for Washington, D. C., as the next meeting place.

Papers and addresses.—In an evening address before the general assembly, W. M. Hays discussed the subject of Education in Breeding. He urged the establishment of agricultural high schools in farming districts, and schools for mechanic arts and home economics in cities, which could be effectively accomplished by appropriations amounting to 20 cents per capita. In this connection reference was made to the recent progress along this line in Georgia. The consolidation of rural schools and the establishment of agricultural high schools were considered necessary steps in making available to the people the results of agricultural research, for which liberal appropriations are now being made. With a system of agricultural instruction extending from the university to the consolidated rural school, it was considered possible to have centers for animal and plant breeding at the State station and branch stations. The work of a plant-breeding station which has been in existence in Minnesota for 15 years was illustrated by means of moving pictures.

One of the most interesting features of the meeting was an address on Breeding Cattelo, by C. J. Jones. The cattelo is a cross between the buffalo and domesticated cattle. Much progress has been made in breeding the cattelo, as also in crossing mountain and domesticated sheep. This work, originating with the speaker, will henceforth be carried on in cooperation with this Department. Much information was also given concerning the buffalo in its wild state and of the efforts being made to preserve the species.

Breeding Beef Cattle in Ohio was discussed by J. P. Hine. The speaker objected to the great difference in market prices between heifers and steers, stating that this difference, amounting in some instances to \$2 per hundred-weight, is the greatest imposition the beef-producer has to contend with. It was noted that this discrimination between sexes is no longer made in Great Britain.

A paper on Breeding Dairy Cattle, by M. A. Scovell, dealt mainly with the history of the Jersey breed. It was suggested that efforts for the further improvement of this breed should be along the lines of constitutional vigor and yield of milk.

C. W. Gay discussed The Breeding of the American Harness Horse. There is, according to the speaker, a growing demand for this type of horse, which is now produced by chance. Utilizing the American breeds for the production of this type of horse, the speaker suggested keeping on the top cross a standard-bred sire of the heavy harness type and using for dams mares of the American saddle or preferably of the Morgan breeds. Going outside of native breeds, the speaker would suggest the use of an English hackney dam.

The Teaching of Animal Selection or Animal Judging was discussed by C. S. Plumb. Methods of teaching animal judging to students in agricultural colleges were briefly presented.

R. H. Johnson, in discussing the subject What the Poultry Breeder Can Learn from the Cattle Breeder, compared the two lines of animal breeding as regards (1) quality of stock, (2) selection, (3) competitive shows, (4) performance records, (5) centgener power, and (6) performance tests. In many respects the poultry breeders were shown to be behind the cattle breeders. Special emphasis was laid upon performance contests. The speaker was in favor of securing individual records, of making the competition one between individuals and strains rather than breeds, and of instituting contests in which not only egg records but gain in weight in proportion to food consumed should be taken into account.

C. B. Davenport addressed the association on The Inheritance of Pedigree Breeding in Poultry. The different forms of inheritance recognizable in hybridization were stated as follows: (1) Inheritance is alternative, i. e., one of the two contrasted conditions of a given organ is dominant over the other and alone appears in the progeny; (2) inheritance is particulate, i. e., both of the contrasted characters appear in the offspring side by side in a patchwork; (3) inheritance is blending, i. e., the opposed characters being quantitatively unlike, the offspring are approximately intermediate between the two parents; and (4) inheritance is neomorphic, i. e., a characteristic appears in the hybrids that can not be seen in the parents. In illustrating these laws the speaker considered various characters, such as color of plumage, form of comb, etc., in hybrids.

The processes necessary for the creation of a new race which shall combine various desirable characters found in two or more races were summarized by the speaker as follows: (1) Hybridization by which the desired combination may be obtained at least in the second hybrid generation; (2) purification of the race by the elimination of germ cells carrying the characteristics that are opposed to those sought; and (3) selection of the best breeding individuals as parents, by which there will be obtained a larger percentage of offspring of the best quality. This work of obtaining and fixing a desirable characteristic will, of course, be hastened if there can be found some individual which is prepotent in respect to that characteristic.

In discussing The Production and Fixation of New Breeds, W. E. Castle gave the results of extended investigations in crossing rats. The variation following crossing was considered due largely to the production of new combinations of unit characters. Such combinations may be fixed by selection. Inbreeding is not essential. No fixation is required when crossing results in a blend rather than in alternative inheritance.

In summarizing the results of his experiments, the speaker stated that where Mendelian inheritance is involved new characters are produced by cross breeding by the forming of a mosaic differing from either parent, or by the becoming visible of an element previously invisible in one of the parents. The fixation of the new character will consist in securing gametes which separately contain all the factors necessary for the production of the new character. When the

characters are previously separated complete fixation may be secured in two generations. When the new character is a mosaic a longer time is required, as gametic contamination which is non-Mendelian in character is involved.

Rejuvenation by Hybridization was the subject of an address by Q. I. Simpson. The vigor or energy of offspring, according to the speaker, is affected by four factors—hybridization, crossing, change of nutrition, and change of climate. These factors were explained and illustrated in connection with a discussion of the author's theory of "cell polarity," which has to do with the origin and function of centrosomes.

G. M. Rommel discussed The Inheritance of the Size of Litter in Poland China Sows. Brief reference was made to the results of studies reported in Circular 95 of the Bureau of Animal Industry (E. S. R., 18, p. 267). More recent studies of the inheritance of the size of litters from mother to daughter were reported. The later results showed that the size of the litter increases with the age of the sows from 1 to 5 years. The results also showed a tendency toward the transmission of the size of litter, this being most marked in the case of the youngest daughters.

E. C. Schroeder, in discussing Animal Breeding and Disease, stated that disease is a disqualifying condition in any animal from which the highest type of progeny is expected. This was illustrated by reference to specific diseases. Means of eradicating certain diseases, especially tuberculosis, were discussed. Special attention was called to the spreading of disease by the growing custom of stabling animals by classes in exhibitions instead of by owners. Among other topics discussed was the inheritance of susceptibility to disease. Tests carried on for ten years have shown that the susceptibility of hogs to hog cholera varies from an extremely high grade to absolute immunity. Great variation was also observed in the susceptibility of cattle to Texas fever and other diseases. Efforts are now being made to obtain a breed of hogs immune to cholera by breeding from naturally immune stock. Mention was also made of other lines of work similar in character in which the Bureau is engaged.

Corn Breeding and Registration was discussed by C. G. Williams, who considered the ear-row test the proper basis for this work. Ears for this test should be selected upon the growing plant in order that environment may be noted and the first step taken in sifting the inheritably good from the accidentally good. The ear-row test may be employed without regard to other cornfields. In order to overcome differences in environment this test should be made in duplicate, with uniform check rows at regular intervals. The value of this duplication was illustrated by the work of Ohio breeders.

One-third to one-half of the seed grain of each ear should be saved for use in the breeding plats when the test has demonstrated which the high-yielding ears are. The remnants of the high-yielding ears are crossed the year following the test, one being used as sire upon several detasseled dams. A plan for continuous corn-breeding work was presented in which inbreeding was thought to be provided against. Rules were given for the registration of pedigreed and merged strains of corn as adopted by the Ohio Plant Breeders' Association.

The breeding of tobacco with particular reference to the work of this Department was discussed by A. D. Shamel.

A review of Tobacco Breeding in Ohio was presented by A. D. Selby. The State has four tobacco districts in which characteristic and distinct varieties are grown. Efforts at crossing the Connecticut seed leaf with the Cuban seed-leaf tobacco in the cigar-filler district have resulted in the production of 35 or more hybrids which are being tested. New wrapper tobacco hybrids have also been produced and are being subjected to tests.

W. H. Scherffius presented a report on Tobacco Breeding in Kentucky. Attention was called to the fact that Kentucky produces more than one-third of the output of tobacco of the United States, and fertilizer and variety tests were reported. White Burley tobacco has given better results than crosses of this variety with Connecticut, Havana, and Sumatra varieties. The protection of the seed heads from cross fertilization by bagging and the use of the seed separator have resulted in the production of better and more uniform crops.

C. W. Waid reported the Results of Hill Selection of Seed Potatoes. Seed was selected from high and low yielding hills and from hills resistant to disease, the work being carried on at the Ohio Station for three years. In general the results showed an increase in the yield of potatoes when the seed had been selected from high-yielding hills, and a decrease when the seed had been selected from low-yielding hills. The selection of seed from high-yielding hills is therefore recommended. Selection from hills showing resistance to early blight has given very encouraging results.

The Improvement of Sugar Cane by Selection and Breeding was discussed by C. O. Townsend. Several difficulties encountered in the improvement of sugar cane by vegetative selection or breeding were mentioned, such as confusion of names, nonstability of characters, and size and position of flowers. The principal points aimed at by cane breeders were enumerated and summed up in the statement that the cane most desired is the one that will yield the largest quantity of sugar per acre with the greatest certainty and the least expense. In the work already done much progress has been made in increasing the yield of cane and also the sugar content, in securing varieties more or less resistant to disease, and in developing varieties suited to different soil and climatic conditions. Improvement by seminal variation has so far given the most satisfactory results.

J. E. W. Tracy discussed Breeding of Sugar Beets to Increase the Sugar Content and Yield Per Acre and the Encouragement of the Sugar-beet-seed Industry in America. It was considered possible to increase the available sugar in sugar beets grown in the United States at least 2 per cent by the use of better seed, and also in the same manner to increase the yield of sugar beets per acre to a marked extent. Mention was made of the efforts being put forth in this country to establish pedigree strains of seed. Sugar-beet growers were urged to produce their own seed, in which work the Department of Agriculture is willing to cooperate.

In discussing the Breeding of Clover, S. M. Bain reported finding individual clover plants very resistant to disease.

A paper by F. Dörner, *sc.*, on Carnation Breeding contained a brief history of the carnation, a description of methods employed in breeding, and an enumeration of the requirements of a good carnation. Breeding experiments have been carried on by the author since 1889. J. B. Norton described some experiments in breeding carnations carried on in the Department of Agriculture, illustrating his remarks with lantern slides showing the results of hybridization.

The Importance of the Mutation Theory in Practical Breeding was discussed by G. H. Shull. The speaker called attention to the large number of unexpected variations which have formed the starting point for the production of new strains, and mentioned the need of care in order to avoid confusion in distinguishing mutations from forms produced by hybridization. Mutations were considered the basis of every permanent seed strain. According to the speaker, the method of breeding in order to harmonize with the mutation theory should consist in the production of as large number as possible of seedlings among which to seek valuable mutations; as complete isolation of selected individuals as their breeding habits will permit and complete control of fertilization, and the rearing of the offspring under conditions that will allow all distinguishing

characteristics to reach a normal development. It was stated that these requirements are more or less closely approximated by the various isolation methods now in use.

S. M. Tracy showed by numerous illustrations The Importance of Securing Full and Accurate Descriptions of Varieties. The Press and Breeding was discussed by W. I. Chamberlain, mainly as regards the use of illustrations in advertising.

Papers read by title.—C. E. Woodruff submitted a paper entitled: The Prevention of Degeneration is the Only Practical Eugenics. The author maintained that a study of heredity will prove that defects are often due to remedial causes, and suggested that sanitation in its broadest sense is the only practical means for preventing degeneration.

The Evolution of the Bacon Hog in Ontario was set forth in a paper by J. Dryden. This was considered the highest achievement of the Ontario Department of Agriculture while under the guidance of the author. It was stated that the present high and uniform quality of bacon has been attained entirely by selection based on the killing tests. The animals reserved for breeding were selected to supply the same type which won first place in such tests. Close in-breeding was not resorted to.

A Plea for a More Extended Use of the System of Live Stock Registration was made in a paper by M. M. Boyd.

A paper by J. B. Norton discussed the methods of oat breeding, and mentioned results which have already been secured. The principal aim in the breeding of oats in the United States is that of resistance. Plants have already been obtained which are nearly free from smut and rust.

A paper on The Selection of Seed Corn, by C. D. Smith, contained the results of experimental work and suggestions concerning the best methods to be employed in the selection of seed corn.

Statistics of Cotton Variation were reported in a paper by N. D. Shoemaker. The study was undertaken to determine the gain in a desirable character which might be expected from the progeny of a single plant, and how this gain might be affected by cultivation and seasons. The results are interpreted as favoring the check-row system, making a large number of selections, and the keeping of fairly complete progeny records.

H. H. Groff called attention to certain results which have been secured by him in growing gladioli; and The Ease and Importance of Improving the Varieties of Cultivated Nuts was discussed in a paper by J. R. Smith.

A paper by N. E. Hansen entitled, A Plant Breeder's Trip to Eurasia gave notes on a journey around the world, made primarily for the purpose of tracing the northern limits of alfalfa in Asia. L. J. Briggs submitted a paper entitled Grading in Agricultural Judging Contests, in which a system of preparing grading tables was presented. Disseminating New Varieties of Plants, by C. W. Ward, was also read by title.

Reports of committees.—A verbal report on cooperation in animal breeding was submitted by W. M. Hays. Special mention was made of the project for the determination of the value of the dual purpose cow, as represented by the milking Shorthorns, now being carried out by the Minnesota Station in cooperation with the Department of Agriculture.

A verbal report on animal hybridization was submitted by W. J. Spillman. The committee has devised a system of keeping records for cross-bred animals intended for farmers and breeders generally. It has also undertaken to collect the literature relating to animal hybrids. Some results obtained by the application of scientific knowledge to animal breeding were noted, and the Mendelian law was discussed.

A report on breeding dairy cattle was submitted by A. J. Glover. This was in the nature of disconnected notes rather than a committee report. Among the subjects discussed were the importance of production as compared with conformation in judging dairy cattle, the value of short tests, the determination of prepotency, the relative weight of heart and lungs in dairy and beef cattle, and the effect of food on the health of cows and the quality of the milk.

A verbal report on breeding wild birds was submitted by T. L. Palmer. This subject was discussed as regards the importation of wild birds, raising wild birds in a state of nature, the breeding of wild birds in quantity under domestication, and the breeding of birds for a specific purpose, such as the crossing of wild and domestic turkeys in order to secure a race resistant to blackhead. Many instances of the importation of wild birds were mentioned, and the efforts being made to restore to some extent some of the birds now disappearing, such as the eider duck, were described. The speaker called attention to State legislation restricting the capture and shipment of wild birds as a serious difficulty in the way of breeding experiments.

A report on theoretical research in heredity was submitted by C. W. Ward. This consisted essentially of a review of recent advances in the theory of breeding, by C. B. Davenport, and an outline of some of the more important problems in theoretical research relating to heredity, by W. J. Spillman, both members of the committee. According to Doctor Davenport, the newer investigations are revealing certain laws accessory to or modifying Mendel's law. In the first place, Mendel's law of dominance is not universal as characters occasionally blend. Reversion, moreover, constitutes a special case of inheritance in hybridization and does not stand in opposition to the ordinary laws of inheritance. Unpublished data of the author indicate that account should be taken of the immediate characters of the parents as well as of their ancestry. Pure dominants, in the author's experience, can usually be distinguished from heterozygous dominants without resort to breeding tests. Subjects mentioned especially by Professor Spillman as deserving investigation are the relation of the extra chromosome to sex, the relation of chromosome to hereditary characters, and the correlation of characters.

A report on breeding cereals, by L. S. Klinck, dealt with the following subjects: (1) Search for foundation stocks, (2) method of starting foundation stocks, (3) selection, (4) distribution, (5) problems for the different cereals, and (6) crossing and hybridization. Under these headings the report summed up in a general way some of the problems that confront breeders of cereals. It was suggested, for instance, that comparative tests should be made of the centgenet method and the row, drill, and Burbank methods in obtaining new foundation stocks. More investigation was considered necessary to determine whether the individual is the best basis for selection in all the various crops. It was considered desirable that more data should be secured on the best means of distributing improved seed. Some of the problems to be met by the breeder of wheat, oats, barley, rye, durum wheat, emmer, and corn, were enumerated, and it was suggested that each crop be assigned to a subcommittee for a fuller report.

A report on corn breeding, submitted by J. D. Funk, dealt with the value of the score card from the standpoint of the breeder, and the methods of breeding now employed. The mating of individual plants was suggested as a valuable supplement to the ear-row test.

The committee on breeding cotton, in a report read by title, stated that it was undertaking to investigate and standardize methods to be used in breeding this crop. It is the plan of the committee to present individual papers each year rather than a committee report. The paper presented at this meeting was by

the chairman, H. J. Webber, and dealt at length with methods of pedigree breeding recommended for use in breeding cotton.

Several other committee reports were read by title.

Dry Farming Congress.—The Trans-Missouri Dry Farming Congress was organized at Denver, January 24, with an attendance of about 300 delegates and over 700 visitors. A two-day session had been planned, but the interest manifested was such as to prolong the convention an additional day. Addresses were delivered by representatives of this Department and a number of the western agricultural colleges and experiment stations, Governor Buchtel of Colorado, and many others, on various aspects of dry farming, such as cultural methods, irrigation, stock raising, and related problems. Resolutions were adopted advocating the establishment of experimental and demonstration farms, and the distribution of accurate information by the National and State governments. Fisher Harris, of Utah, was elected president, and it was decided to hold the next convention at Salt Lake.

Botany and Agriculture in Ceylon.—The development of the Royal Botanic Gardens at Ceylon, their work for agriculture, and the establishment of experiment stations are described by Dr. J. C. Willis, director of the gardens, in a recent issue of *Science Progress* (1906, No. 2, pp. 308-324).

These gardens were established as early as 1810, and along with their systematic studies did a good deal of economic work under their early directors upon such plants as cinchona, tea, coffee, rubber, and cacao. During the last 10 years, the writer says, they "have grown entirely beyond the conception of botanic gardens, and have become practically a department of agriculture, though the name of 'botanic gardens' is still retained, and the work of purely botanic gardens is still carried on among many new lines of work." An entomologist was attached to the gardens in 1899, and a mycologist two years later. More recently a chemist has been appointed and laboratories provided.

The work of these specialists has brought about a complete change of attitude on the part of British planters, who had previously followed the plan of concealing any outbreak upon their plantations. "So far has opinion turned in the opposite direction from that which it formerly occupied, that the newspapers of Ceylon are now among the first to draw attention to any slight outbreak of disease, and to call for the help of the mycologist or the entomologist."

Two experiment stations have also been established where culture experiments are conducted on a larger scale, one in connection with the gardens at Peradeniya and the other at Maha-iluppalama. The former is in the "wet" zone of Ceylon and in the European planting districts. Its experiments are mainly with cacao, rubber, tea, citronella, and ground nuts, and with lemon grass as a possibly paying new product. It has 20 acres in tea, 15 acres in lemon grass, and other crops in proportion. The station at Maha-iluppalama "lies in the almost uninhabited 'dry' zone of Ceylon," and the experiments have been mainly with cotton, which they indicate may be made a crop of considerable value to Ceylon.

The work of the stations also extends to the maintenance of soil fertility, methods of harvesting various crops, preparation for market, etc. "Much valuable work has been done upon the different ways of preparing the best quality of marketable rubber, upon the best ways of distilling oil of citronella or of lemon grass, upon the best ways of fermenting and drying cacao, and similar problems." From being looked upon somewhat askance, the stations are now appreciated and looked to for aid, and "are beginning to foster that most desirable spirit among the planters, the experimental habit of mind."

EXPERIMENT STATION RECORD.

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau requests and remittances should be directed to the Chief of the Bureau. The price of the Record is \$1 per volume, or 10 cents per number. The prices of other technical publications are given in the list above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XVIII.

APRIL, 1907.

No. 8.

The act making appropriation for the National Department of Agriculture is each year becoming a more important factor in the working out of public policy. The development of the Department has gradually led up to a variety of large national questions, and the consideration of the agricultural appropriation bill in Congress is made the occasion of extended discussion of these broad questions out of which a public policy relating to them is being developed. The bill frequently receives more attention than that for any other executive department, this attention being far out of proportion to the amount of money involved, although not to the importance of the subject matter itself. The greatly increased interest in agriculture in a national sense and in the Department's work has grown out of an increased realization of the importance of agriculture as a great basic industry, largely contributory to wealth, production, commerce, and other industries, and touching the interests and prosperity of the country and the people as a whole.

Last year the Federal meat inspection law was enlarged and greatly developed so as to place the Department in control of all meat products for interstate commerce and for export, and of the sanitary conditions of the establishments where they are prepared. The act also established the policy relating to the management of the forest reserves, and interpreted the Adams Act doubling the appropriation for agricultural experiment stations.

This year the appropriation act also contained important legislation relating to the management of funds arising from the forest reserves, carried a permanent increase for agricultural education which will double the present appropriation in five years, extended the Federal inspection to include human foods, and increased the aid to be given in the eradication of the Texas fever cattle tick in the South, and the gypsy and brown-tail moths in the New England States. A proposition looking to the protection of the grazing lands of the public domain, by placing them under the control of the Secretary of Agriculture, with authority to organize grazing districts, to regulate their use, issue permits or leases, etc., was considered at length but failed of passage.

The inspection duties of the Department are steadily increasing. In addition to the meat and food inspection, the amount for grain inspection is increased from \$15,000 to \$40,000, and the inspection of seeds of grasses, clover, and alfalfa is continued. This police work is quite a new feature and is one of the noteworthy tendencies in the development of the Department. Without necessarily centralizing this service, there are manifest advantages to the country at large from a uniform control of certain products intended for interstate shipment, and a much broader and more effective influence is exerted than could be the case by the States working alone and independently.

The act marks a more liberal tendency in the matter of salaries. There were material increases in the salaries of the Secretary, Assistant Secretary, and the chiefs of three bureaus, the latter being brought up to \$5,000. A provision was also inserted raising the maximum salary which the Secretary is authorized to pay to investigators or others engaged in scientific work from \$3,000 to \$3,500. This is gratifying recognition of the merits of such service as compared with that in other branches of Government and scientific work, and of the position which agricultural investigation is attaining.

The total amount carried by the agricultural appropriation act for 1907-8 is larger than in any previous year by nearly \$3,000,000. The appropriation for "routine and ordinary work" is \$8,692,290. The emergency appropriations and the increase for the agricultural colleges for the coming year bring the total up to \$9,447,290, to which should be added a permanent appropriation of \$3,000,000 for meat inspection. If to this is added the Adams fund for next year, amounting to \$432,000, which is administered by the Department and hence is quite as properly included here as the Hatch fund, the grand total is \$12,879,292. The amount exceeds the appropriation of two years ago (1905-6) by over \$6,000,000, and represents an increase of nearly 100 per cent. This increase is in large measure covered by the extension of the inspection work of the Department upon meat and other articles of food.

The Bureau of Animal Industry now greatly exceeds all other Bureaus in the amount of its fund. Its regular appropriation is \$1,032,480, a net increase of \$85,500 over last year. To this is to be added the funds for the eradication of the cattle tick in the South, which is increased from \$82,500 to \$150,000, with \$25,000 made immediately available, and the permanent appropriation of \$3,000,000 for executing the meat inspection law. The latter was made permanent legislation. The appropriation for animal-breeding experiments was increased from \$25,000 to \$50,000, and an attempt to restrict one-

half to horse breeding failed. The fund for developing the dairy industry in the South, which was included last year, was not renewed. The provision for experiments in cooperation with the Minnesota Station with a view to developing antitoxins or preventive vaccines was continued.

The Weather Bureau was given a slightly smaller appropriation than the previous year, the amount being \$1,413,540. The usual appropriation for the erection of buildings was stricken out on a point of order, and the cost of maintenance of the printing office was limited to \$18,000.

The Bureau of Plant Industry was increased \$132,490, the total appropriation being \$1,052,230. This increase was largely for general maintenance and extension of the present lines of work, but included an increase of \$25,000 for the grain inspection, as previously noted. The fund for the Congressional seed distribution, in spite of the extended discussion of its merits, was retained in the bill as passed, the amount being \$238,000, of which \$36,000 may be used for the introduction of seeds and plants from foreign countries. In addition to the above amounts, the Bureau received a considerably larger proportion of the emergency appropriation for cotton boll weevil work, the amount assigned to it being \$150,000, out of a total of \$190,000.

The amount for the Forest Service was increased to \$2,400,000, but \$1,000,000 of this was in lieu of the estimated receipts from the reserves, which must henceforth be turned into the Treasury instead of being used in their management. The sum of \$500,000 was appropriated for "the proper and economical administration, protection, and development of the National forests," \$125,000 of which is immediately available. Authority to conduct experiments and investigations in Washington was refused. The authority of the President to establish forest reserves was rescinded, it being stipulated that future reserves or additions in Oregon, Washington, Idaho, Montana, Colorado, or Wyoming are to be made only by act of Congress. In response to the widespread movement for the establishment of forest reserves in the Appalachian and White mountains, authority was given for a survey and report on these watersheds with regard to their area and natural conditions, the price at which they can be purchased, and "the advisability of the Government purchasing and setting apart the same as national forest reserves for the purpose of conserving and regulating the water supply and flow of said streams in the interest of agriculture, water power, and navigation." Twenty-five thousand dollars was appropriated for this purpose and made immediately available.

The Bureau of Chemistry received \$650,000 for general maintenance, including the execution of the pure-food law, which, with

the statutory roll, brings its total up to \$697,920. The provisions for fixing standards and for the inspection of imported food products, which were carried by the last appropriation act, were stricken out. All sums or compensation paid to State or local officials in connection with the food-inspection work are to be reported in detail to Congress not later than next March. Sufficient authority for the fixing of standards and other duties in connection with the execution of the law are believed to be contained in the pure food law.

For the Bureau of Entomology the amount was increased to \$136,010, an increase of \$41,400, \$10,000 of which may be used in experiments looking to the eradication of the "white fly." Tobacco insects, especially in Kentucky and Tennessee, are included in the list of pests to be studied. The Bureau receives \$40,000 of the appropriation for cotton boll weevil work, and an increase in the emergency appropriation for combating the spread of the gypsy and brown-tail moths from \$82,500 to \$150,000, the appropriation being made immediately available.

The Bureau of Statistics receives an increase of \$8,380, its total appropriation being \$219,940, for the collection of statistics and the study of foreign markets.

The appropriation for the Bureau of Soils was decreased \$15,000, in view of the assignment of certain features of the tobacco work of the Bureau to the Bureau of Plant Industry. The amount carried by the act is \$206,980.

The Office of Experiment Stations received a considerable increase in the statutory roll and in the appropriation for various lines of work. The general maintenance fund was made \$30,000, and the appropriation for the Alaska, Hawaii, and Porto Rico experiment stations was increased \$9,000 in the case of each, in order to make the amount equal to that received by the State stations under the Adams Act. For irrigation and drainage \$150,000 was appropriated, an increase of \$27,800 over last year, and the \$5,000 for farmers' institutes and agricultural schools was continued. The general appropriation for nutrition investigations was stricken out on a point of order, but subsequently a clause was inserted providing \$5,000 for packing, moving, and storing the respiration calorimeter now housed in one of the buildings of Wesleyan University. The total appropriation for the Office, including that to the stations under the Hatch Act, is \$1,013,220.

The same appropriation was made for the Biological Survey as last year, \$52,000, but the Secretary was directed to report to what extent, if any, the work now being done by the Survey is duplicated by any other Department of the Government, and the practical value of the work to the agricultural interests of the country.

The appropriation for the Division of Publications was \$161,550,

but this does not include, as was formerly the case, the amount for printing Farmers' Bulletins, which from now on is carried in the sundry civil act. The amount there designated for this Department, to include the first cost of the Yearbook and the miscellaneous reports which are made to Congress, is \$433,750, of which amount \$98,750 is for Farmers' Bulletins, and \$25,000 for the publications of the Weather Bureau.

The Office of Public Roads received the same appropriation as last year, \$70,050, and the Library \$28,380, an increase of \$2,500. Other items of the act are Office of the Secretary \$119,200, Division of Accounts and Disbursements \$41,790, and contingent expenses \$47,000.

The increase in the appropriation for the colleges of agriculture and mechanic arts is a matter of much gratification to all interested in the progress of these institutions and familiar with their need of additional funds. It reaffirms the policy of the General Government to favor and develop these land-grant institutions, legislation for which has now extended over a period of 45 years.

The act of 1862 donated to the States and Territories lands from which over \$12,000,000 has been realized as a permanent endowment, with over \$4,000,000 worth still unsold. The supplementary act of 1890 has given them \$1,200,000 annually for more than a decade past; and the present act, known as the Nelson Act, increases the amount to each State \$5,000 a year for five years, when the appropriation will be double that at present and will be continued permanently at that rate. Although the new measure is carried by the agricultural appropriation act, it will be administered like the Morrill fund by the Bureau of Education, and not by the Department of Agriculture.

The appropriation was carried through on the merits of agriculture. The law itself mentions the agricultural work prominently, and the discussion in Congress hinged almost exclusively on the value and growing importance of agricultural education, and the needs of developing that phase of our educational system. These needs in connection with our colleges are very acute, as every one will admit who is familiar with the relatively meager equipment in men and materials for instruction in that branch. Now that the methods of instruction have been worked out on a broader and more efficient basis, and the desire for instruction in agriculture has become more widespread, it is fair to expect that the land-grant colleges the country over will recognize the opportunity presented by this new appropriation to develop and strengthen agricultural education.

Press dispatches report the death at Paris, France, March 18, of Pierre Eugène Marcellin Berthelot, the distinguished French statesman and scientist, whose work contains much of interest and value to agriculture.

Berthelot was born in Paris October 25, 1827. Early in life he showed marked taste for philosophical studies and chemical research, and during the more than fifty years of his unusually active and productive scientific career, beginning practically with the enunciation of his theory of polyatomic alcohols in 1854, his work has covered nearly every branch of chemistry and included besides many important contributions to physics, botany, and agriculture. Indeed his scientific work is preeminently distinguished by its breadth of conception and the boldness and success with which he made all departments of science concerned contribute to the investigations he undertook, thus attesting an extraordinary breadth of knowledge and sureness of grasp of science in many fields. To an unusual degree he made science in its various departments subservient to his purpose in working out the particular problem which he had under investigation.

Berthelot's philosophy and science was of that constructive kind so well exemplified by those researches in synthesis of organic compounds beginning in 1854 and continuing to the end of his career, which give him his strongest title to fame. When he began his work in this line Wöhler had already prepared urea synthetically from its inorganic constituents, and a few other syntheses of similar character had been made, but, as a recent writer states, "they were so isolated, so insignificant, and so barren of fruit that all attempts to constitute organic bodies by bringing together the elements of which they are composed were as a rule regarded as chimerical." Yet Berthelot attacked this problem with such energy that in a comparatively short time he greatly increased the number of synthetically prepared organic compounds entering into the composition of living organisms, and elucidated the laws and devised a system of processes by which organic compounds may be formed from inorganic elements. In fact it may be said that he introduced the synthetic method into organic chemistry.

Among the important compounds thus prepared by him were oxalic and formic acids, methyl alcohol, glycerine, camphor, oils, and acetylene. The ultimate aim of his efforts in this direction was the production of albuminous and carbohydrate bodies, of which he said: "The reconstitution of the saccharine and albuminoid principles is the final object of organic chemistry, the most remote one indeed, but also one of the most important, on account of the essential part which these principles play in our economy. When science attains it, it will be able to realize the synthetic problem in its whole extent—that is, to produce, with the elements and by the play of molecular forces alone, all the definite natural compounds and all the changes which matter undergoes in the bodies of living beings."

Berthelot expressed the belief that the synthesis of the food nutrients, fats, and sugars will probably be followed by the artificial prep-

aration of others until ultimately all food materials, beverages, condiments, narcotics, etc., will be made by artificial processes instead of derived from natural products.

In connection with his studies of the thermal relations of respiration and tissue building in plants and animals, Berthelot made important contributions to thermo-chemistry. The bomb calorimeter, which is now extensively used in the study of the fuel value or heats of combustion of foods and feeding stuffs, is a product of his labors in this direction. He also successfully applied the bomb calorimeter in the development of a new method of elementary organic analysis.

Berthelot's more strictly agricultural contributions were very large and of the highest order of importance. He was among the first to demonstrate the fixation of free nitrogen in the soil by microscopic organisms, independent of or in symbiosis with higher plants. He has probably done more than any other modern scientist to explain the true nature of the humus compounds of the soil. His *Plant and Agricultural Chemistry (Chimie Végétale et Agricole)*, the publication of which was begun in 1899, and which consists of four volumes containing about 2,000 pages, is a collection of the reports of the work of the author, especially at the station for plant chemistry at Meudon, which appeared from time to time in the *Annales de Physique et Chimie*. The first volume deals with the fixation of free nitrogen by soils and by plants, the second is devoted to general studies on plant growth and the chemical action of light, the third includes special studies on plant growth, and the fourth is devoted to studies of cultivated soils and of wine. In recent years he had made important and interesting contributions to the history of chemistry.

The varied and valuable character of Berthelot's contributions to agricultural science will be evident to any one who will take the trouble to consult the files of *Annales de Physique et Chimie*, *Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences*, or this journal. The latter will show references to some forty important contributions on agricultural subjects within the last fifteen years.

Berthelot's eminence in science was recognized throughout the world and he received many honors, political as well as scientific. He was a life member of the French Senate, and had been successively Inspector-General of Higher Education, Minister of Public Instruction, and Minister of Foreign Affairs. He was a grand officer of the Legion of Honor, and succeeded Pasteur as permanent secretary of the French Academy of Sciences. He was a member of the Institute of France, as well as of the most distinguished scientific societies of other countries.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

The determination of nitrogen in nitrate of soda, U. VAN DAM (*Rec. Trav. Chim. Pays-Bas et Belg.*, 25 (1906), pp. 291-296; *abs. in Chem. Abs.*, 1 (1907), No. 2, p. 152; *Jour. Chem. Soc. [London]*, 90 (1906), No. 530, II, p. 898).—A method based upon the oxidation of oxalic acid by the nitrate in presence of manganese sulphate with subsequent determination of the excess of oxalic by titration with potassium permanganate, is described, and comparisons of it with the Schloesing method are reported. The oxidation is effected by heating the mixture at 100° C. for 3½ hours in a flask provided with a reflux condenser and charged with carbon dioxide.

Detection of nitric acid, P. SOLTSEIN (*Pharm. Ztg.*, 51 (1906), No. 69, pp. 765, 766; *abs. in Chem. Centbl.*, 1906, II, No. 12, pp. 1020, 1021; *Jour. Chem. Soc. [London]*, 90 (1906), No. 530, II, p. 898).—The interference of nitrous acid with the diphenylamin and brucin reactions is noted and attention is called to the fact that in testing for nitric acid by reduction to nitrous acid with zinc the reduction may be carried so far that the formation of starch iodid will be prevented. It is recommended that in presence of such substances as ferric or manganic oxids metadiamido benzol be used. Attention is called to the occurrence of traces of nitrate in filter paper.

Phosphomolybdic acid as a reagent for potassium, A. SCHLICHT (*Chem. Ztg.*, 30 (1906), No. 104, pp. 1299, 1300; *abs. in Analyst*, 32 (1907), No. 371, p. 64).—Attention is called to the fact that phosphomolybdic acid forms with potash insoluble compounds of constant composition, and studies by the author of the reaction under various conditions indicate that it may be employed with advantage as a means of quantitative determination of potash. The reagent used consists of a nitric-acid solution of phosphomolybdic acid prepared by fusing ammonium phosphomolybdate with sodium carbonate and nitrate and dissolving the fusion in water acidified with nitric acid. The reagent is added to the nitric-acid solution of the potash salt and the yellow potassium phosphomolybdate is precipitated by heating the solution. Calcium, magnesium, and sodium compounds do not interfere, but ammonium salt, of course, gives the same reaction.

Causticizing of alkali carbonates by lime, M. LE BLANC and K. NOVOTNY (*Ztschr. Anorgan. Chem.*, 51 (1906), pp. 181-201; *abs. in Jour. Soc. Chem. Indus.*, 25 (1906), No. 23, p. 1145; *abs. in Jour. Chem. Soc. [London]*, 92 (1907), No. 531, II, p. 22).—The authors report determinations by direct and by conductivity methods of the solubility of calcium carbonate in water at 18 and 100° C. The amounts dissolved at these temperatures were 13 and 21 mg. per liter respectively, of which 65 and 72 per cent, respectively, were hydrolyzed, leaving the amounts actually in solution as carbonate 4 mg. per liter at 18° and nearly 6 mg. per liter at 100° C.

From these data and from others for the solubility of calcium hydroxid the authors calculated the equilibrium constants for the reaction of calcium hydroxid on potassium or sodium carbonate and also carried out experiments, starting both with alkali carbonate and lime and with alkali hydroxid and calcium carbonate. The results showed in general that the temperature and also the pressure were practically without influence on the final result. The

speed of reaction was perhaps greater at higher temperatures, but equilibrium was in all cases rapidly reached.

The most complete conversion of alkali to hydroxid (98.1 to 99.1 per cent) was obtained in case of normal solutions of alkali carbonates at 100° C., the lowest (about 92 per cent) with thrice-normal alkali carbonate, which was the strongest solution used, the results with twice-normal carbonates being intermediate.

Determination of formaldehyde in milk, F. W. RICHARDSON (*Jour. Soc. Chem. Indus.*, 26 (1907), No. 1, pp. 3, 4).—This is a preliminary note on efforts being made by the author to devise a method for the quantitative determination of formaldehyde in milk and other materials.

Sulphuric acid containing 0.05 per cent of ferric sulphate is added drop by drop to 5 cc. of milk in a porcelain dish with vigorous stirring after each addition. The liquid so obtained may be diluted with a mixture of sulphuric acid and water in equal parts in order to make color comparisons in glass cells by Lovibond's system. By this means the author estimates colorimetrically 0.002 mg. of formaldehyde.

In determining formaldehyde in aqueous solutions by this method it is necessary to add some albuminoid substance, and tests are being made to determine which will give the deepest color. Other nitrogenous bodies than albumoses have been found to give this reaction.

The estimation of preservatives in milk, H. S. SHREWSBURY (*Analyst*, 32 (1907), No. 370, pp. 5-14).—Tests of methods for the determination of formaldehyde and boric acid in milk are reported.

A new apparatus for the rapid and accurate determination of the fat content of milk, J. ADORJAN (*Ztschr. Landw. Versuchsw. Österr.*, 9 (1906), No. 12, pp. 1063-1066, fig. 1).—A modification of the Gottlieb apparatus is described.

A simple fat extraction apparatus, G. S. FRAPS (*Amer. Chem. Jour.*, 37 (1907), No. 1, pp. 85-87, fig. 1).—The author describes this mercury sealed apparatus as having some points of resemblance to Knorr's, but being much simpler in construction and less expensive.

Detection of the adulteration of butter with cocoanut oil and oleomargarin, L. ROBIN (*Ann. Chim. Analyt.*, 12 (1907), No. 1, pp. 14, 15).—Applying methods to which reference has already been made (E. S. R., 18, p. 419), the author finds that dividing the index of saponification of pure butter by the percentage of fatty acids soluble in water gives a quotient in no case exceeding 39. The same procedure applied to margarin gave 1.791, to cocoanut oil figures varying from 1.29 to 1.42, and to mixtures of butter and 10 per cent of margarin or cocoanut oil figures above 39 in 48 out of 50 cases.

On the detection of cotton-seed oil, N. PETKOW (*Ztschr. Öffentl. Chem.*, 13 (1907), No. 2, pp. 21-25).—Studies were made of the Halphen and Becchi reactions.

The two reactions are not believed to be dependent upon the same substance. The sensitiveness of the Becchi reaction depends upon the relative amount of the silver nitrate solution used. The two tests are considered necessary in determining the presence of cotton-seed oil, inasmuch as certain samples do not respond equally well to both tests. The colorimetric determination of the percentage of cotton-seed oil in mixtures with other oils is considered uncertain as the color of the Halphen test with different cotton-seed oils is not uniform.

Determination of sucrose and of reducing sugars in fluid saccharin products, F. G. WIECHMANN (*Internat. Sugar Jour.*, 9 (1907), No. 98, pp. 68-77).—In view of results obtained in his investigations of the determination of sucrose and reducing sugars in fluid saccharin products, the author recommends for this purpose the retention of the present composition of Fehling's solution,

clarification with basic lead acetate before the determination of the sucrose and reducing sugars, and the exclusive use of a gravimetric method for the determination of both sucrose and reducing sugars. A gravimetric method for this purpose is given.

A rapid method for the determination of water in butter, C. E. GRAY (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 100, pp. 6, figs. 2*).—One form of the apparatus devised for this purpose is shown in the accompanying figure. (Fig. 1.)

FIG. 1.—Apparatus for moisture determination.

Analysis of wine (*Feuille Vin, Gironde, 32 (1907), No. 4, pp. 13, 14*).—This gives the methods for the analysis of wine established by the minister of agriculture for use in the government laboratories of France.

A is a flask of a little over 70 cc. capacity. C is a graduated tube which is connected with flask A by means of a rubber stopper, B. The tube C is graduated after the glass stopper F has been ground into it, the zero mark being the end of the stopper. Each mark of the graduation represents 0.2 cc. E is a glass condensing jacket connected to the graduated tube C by means of a rubber stopper D.

The reagent used is a mixture of 5 parts amyl acetate and 1 part amyl valerianate.

In making a determination a 10-gram sample of butter wrapped in the parchment paper upon which it is weighed is transferred to the flask and 6 cc. of the amyl reagent is added. The apparatus is connected as shown in the figure, the condensing jacket is filled with cool water to within 1 in. of the top, and the stopper F is removed. The water is then distilled off by heating for 5 to 8 minutes and collected in the tube C. The flask is then disconnected and the stopper F inserted into the tube C. The tube is then inverted, the water in the condensing tube being poured out. The condensing jacket may then be removed. A little swinging and agitation will secure a separation of the water and reagent. The reading made when the tube and contents are cool shows the percentage of water in the butter.

Comparative determinations by this method and the official method of the Association of Official Agricultural Chemists agree closely.

Recent work on protein hydrolysis, J. R. GREEN (*Sci. Prog. Twentieth Cent.* 1 (1907), No. 3, pp. 427-447).—A concise summary of investigations which have been reported in recent years regarding the cleavage and structure of animal and vegetable proteids.

A text-book of sanitary and applied chemistry or the chemistry of water, air, and food, E. H. S. BAILEY (*New York and London: The Macmillan Co., 1906, pp. XVII+345*).—The first part of this volume, which is designed as a text-book for class-room use, is devoted to water, air, heating, lighting, and ventilation, and the second part to a discussion of food and beverages, including food adulteration. Throughout the book experiments are outlined, and the work as a whole constitutes a concise summary of data on the subjects treated.

Practical guide for the detection of adulteration and sophistication of food materials, P. BRETEAU (*Paris: J. B. Baillièrre & Sons, 1907, pp. VIII+386, pls. 8, figs. 143; rev. in Jour. Pharm. et Chim., 6. ser., 25 (1907), No. 2, pp. 89, 90*).—This volume is designed as a handbook for students, and contains descriptions of apparatus, chemical methods, and directions for the detection of the usual adulterants. The preface is by P. Cazenève.

Agricultural chemistry in the first half of the year 1906, W. ZIELSTORFF (*Chem. Ztschr., 6 (1907), No. 1, pp. 1-6*).—A summary account is given of progress in chemical investigations relating to plants and animal nutrition during the period.

Report of progress in inorganic chemical industry during the second and third quarters of 1906, G. RAUTER (*Chem. Ztschr., 6 (1907), No. 2, pp. 17-25*).—The literature of investigation and invention in this field is briefly reviewed. The investigations of special interest to agriculture noted in this review are those relating to the preparation of ammonia and other nitrogen compounds from waste products and from the nitrogen of the air.

Extracts from the proceedings of the association of official agricultural chemists, 1906 (*U. S. Dept. Agr., Bur. Chem. Circ. 32, pp. 14*).—This contains the reports of the committees on recommendations of referees, with the action taken by the association, the report of the committee on the revision of methods, the resolution adopted concerning the next place of meeting, and a list of the officers, referees, and committees for the year 1907. (See also E. S. R., 18, p. 396.)

International catalogue of scientific literature. D—Chemistry (*Internat. Cat. Sci. Lit., 4 (1906) pls. 1, pp. XI + 431; 2, pp. 432-2183*).—This is the fourth annual issue of this catalogue, previous issues of which have already been noted (E. S. R., 16, p. 745). Part 1 is arranged by authors and part 2 by subjects.

METEOROLOGY—WATER.

Some world's weather problems, W. J. S. LOCKYER (*Sci. Prog. Twentieth Cent.*, 1 (1906), No. 2, pp. 206-221, figs. 2).—The great advances in meteorology made possible by improved means of exploring the upper air are referred to and the fundamental relations between barometric pressure and weather changes are discussed with especial reference to the barometric see-saw between nearly antipodal parts of the earth, which has been worked out by the author and Sir Norman Lockyer.

A map illustrating this phenomenon is given, and the general inverse relation between rainfall and pressure in India, Australia, and England during the period from 1870 to 1900 is also charted.

The general conclusions from these investigations on pressure observations are (1) that all over the world changes of long duration are in operation, and

(2) that these changes are not all alike either in intensity or time of duration. "In spite of these marked differences, there seems nevertheless to be an underlying connection between them all. It is not therefore without, but rather within, the bounds of possibility that the time will come when such apparent divergences will all be found to be very closely allied to each other, and be the natural resultants of one or more primary world atmospheric fluctuations."

On certain problems of the hydrosphere and atmosphere, T. C. CHAMBERLIN (*Carnegie Inst. Washington Year Book, 5 (1906), p. 171*).—"This paper proceeds on the assumption that the climatic problems of the earth center about the discovery and elucidation of a system of automatic control of such efficiency as to have kept the temperature of a large portion of the surface of the earth throughout its organic history within the narrow range of 100° C., and at the same time to have kept the constitution of the atmosphere within the like narrow range consistent with plant and animal life.

"The paper recurs to the fourfold organization of a typical atmosphere set forth in [a previous paper], and endeavors to apply the states of equilibrium deduced therefrom to the feeding and depletion of the atmosphere. It is recognized that the hydrosphere is a derivative from the atmosphere, and that its relations of equilibrium with the atmosphere are important factors. The relations of equilibrium between the free atmospheric gases and those absorbed or held in feeble combination in the ocean are considered, together with the conditions and rate of exchange. The discussion of changes in the basis of equilibrium forms a vital factor.

"The function of the ocean as a source of atmospheric storage and supply is discussed and a possible reversal of the deep-sea circulation, alternating with circulation of the present order, is considered as a possible explanation of the alternation of warm polar temperatures with periods of marked glaciation and aridity. The sources of internal supply of atmospheric and hydrospheric material are reviewed and correlated with sources of depletion, so far as practicable. The function of deformation and base leveling in changing the available amounts of the critical atmospheric constituents is set forth. The relationship of the atmosphere's constituents to thermal absorption, retention, and radiation, and the bearing of these upon the climate, are also treated."

On the relations of equilibrium between the carbon dioxide of the atmosphere and calcium sulphate and calcium carbonate and bicarbonate in solutions in water in contact with it, J. STIEGLITZ (*Carnegie Inst. Washington Year Book, 5 (1906), pp. 171, 172*).—"This paper embraces the results of a computation of the varying equilibria subsisting between different degrees of concentration of carbon dioxide in the atmosphere and varying degrees of concentration of calcium carbonate and bicarbonate, and calcium sulphate in solutions in free contact with the atmosphere. It also considers the relative points of saturation of the calcium salts under varying conditions and the consequent order of their precipitation.

"The computations have been developed with reference to their application to certain of the problems of equilibria set forth in a preceding paper, and also incidentally to the order of deposition of evaporation deposits under conditions of aridity and other atmospheric states. They have been limited for the present to two cases, the first when the three calcium salts are present alone, and the second when they are present with other sulphates, of the nature and quantity found in the ocean at the present time."

Weather and crop yield, J. W. SMITH (*Ohio Nat., 7 (1907), No. 3, pp. 48-51, fig. 1*).—"From a comparison of rainfall data and crop yields the author concludes that there is a short period in the growth of crops in which the yield

is greatly affected by favorable and unfavorable weather conditions, and "that the yield can be very closely approximated at the close of this critical period by an exhaustive study of the weather conditions and crop yields of previous years." Thus, charts showing the relation between the yield of corn in the 8 great corn-producing States in this country and the rainfall during June, July, and August during 1888 and 1902 indicated "that the rainfall in July controls the corn yield to a marked extent," and that by this means a very close estimate of the yield of corn per acre in the United States can be made by the latter part of July.

Charts which the author has prepared showing the departure of the average temperature, total rainfall, and crop yields from the normals by months, from 1876 to 1904, indicate a marked relation between the weather and the yield of various crops. The charts indicate that for the best yield of oats June and July should be moderately cool and dry; for barley the summer should be warm and dry; for potatoes a cool summer, with a fair amount of rain in June and July and a dry September; for hay abundant rainfall in April, May, and June. Wheat, rye, and clover are affected by winter conditions such as alternate freezing and thawing, short periods of severe cold, snow covering, etc., more than by monthly temperature or precipitation.

"The dates of blossoming of fruits depend to a marked degree upon the temperature of March and April. In general poor fruit yields have been preceded by cold winters and good yields by comparatively mild winters."

The law of sequence in the yield of wheat for eastern England, 1885-1905. W. N. SHAW (*Jour. Agr. Sci.*, 2 (1907), No. 1, pp. 17-28, figs. 2).—A shorter article on this subject has already been noted (E. S. R., 18, p. 313).

This article discusses in some detail the question of the relation between yield of wheat and autumn rainfall, but more especially an apparent 11-year periodicity in yield as disclosed by a study of the yield of wheat for a selected part of England during the last 21 years. While the relation between yield of wheat and autumn rainfall has in recent studies not been found to be as close as was at first indicated, it still appears that the autumn rainfall is in a way the key to the subsequent seasons, and thus has an important bearing upon the wheat yield. An examination of the meteorological and wheat yield data shows that a wet autumn usually means a relatively dry spring and a deficient crop and vice versa.

Weather charts and reports, and their utility to the Indian agriculturist. W. L. DALLAS (*Agr. Jour. India*, 1 (1906), No. 4, pp. 329-337, chart 1).—This article describes briefly the character of observations on pressure, temperature, humidity, rain, wind, weather, and sea disturbance made at the government observatories in India and attempts to show how weather charts and reports may be utilized by the individual observer "in forming a conjecture as to approaching weather."

It is pointed out that the charts "will be found most useful to those who study them continuously and carefully and combine with them careful and systematic observations of their own meteorological instruments and their local weather. . . . When considering what is the practical use to an agriculturist of weather charts, giving as they do a representation of conditions of weather already passed, it is necessary to acknowledge at once that the utmost they will permit a careful observer to do is to make an intelligent anticipation of coming events, an anticipation which may and indeed must frequently be incorrect, but which on many occasions will not be without value."

To-morrow's weather: How it is foretold. D. A. WILLEY (*Sci. Amer.*, 96 (1907), No. 5, pp. 108, 109, figs. 7).—The preparation of the daily weather map

is explained and the more important pieces of apparatus used in weather observation are described.

The weather (*Ann. Rpt. Bur. Indus. Ontario, 1905, pp. 7-9, 19-23*).—Monthly summaries of observations at the principal meteorological stations in Ontario on temperature, precipitation (rain and snow), and sunshine for each year from 1896 to 1905 and for the period 1882 to 1905 are given.

The climate of extreme southern Texas, J. L. CLINE (*Gulf Coast Line Mag., 2 (1907), No. 3, pp. 30-45*).—Data from the records of the United States Weather Bureau with reference to the temperature and moisture conditions in the Texas coast country are summarized and discussed.

General résumé of climatological conditions and their effect on agriculture in Cuba during 1906, L. G. Y CARBONNELL (*Bol. Ofic. Sec. Agr. Cuba, 2 (1907), No. 1, pp. 30-42, pls. 2*).—Observations on temperature, rainfall, pressure, and sunshine at different meteorological stations in the island are summarized and briefly discussed with reference to general climatological and seasonal conditions by the chief of the meteorological service.

Climatological data for the year 1903 (*Com. Geogr. e Geol. São Paulo Bol. 17, pp. 149, map 1, figs. 8*).—This is a detailed report of operations and observations by the meteorological service of São Paulo, Brazil.

Report on the meteorological observations made at the [Horticultural] Society's garden at Wisley in 1905, R. H. CURTIS (*Jour. Roy. Hort. Soc. [London], 31 (1906), pp. 169-182, figs. 3*).—Observations on temperature of the air in shade and on grass and of the soil at depths of 1, 2, and 4 ft., rainfall, sunshine, and wind movement, are summarized and the general characteristics of the weather are discussed for each month of the year.

Meteorological division, J. LYLE (*Orange River Colony Dept. Agr., Ann. Rpt., 2 (1905-6), pp. 337-351*).—The results of observations on pressure and temperature at 8 stations in Orange River Colony and on rainfall as recorded by 160 rain gages during the year ended June 30, 1906, are summarized.

Meteorology of the year 1906, J. DERÔME (*Rev. Sci. [Paris], 5, ser., 7 (1907), No. 2, pp. 55, 56*).—Observations on pressure, temperature, and precipitation at Pare Saint-Maur during 1903 to 1906 are summarized, with similar data for other places in France and other parts of Europe and Algeria.

Results of meteorological observations at Wiesbaden in 1905, E. LAMPE (*Jahrb. Nassau. Ver. Naturk., 59 (1906), pp. 54*).—Tables give details of observations on pressure, temperature, precipitation, humidity, cloudiness, and wind movement.

On the climate of Rostock with reference to harmonic analysis, J. LOEWENTHAL (*Beitr. Statis. Mecklenb., 14 (1906), No. 4, pp. 48, figs. 3, charts 3*).—Observations on temperature, pressure, precipitation, humidity, cloudiness, wind movement, electrical phenomena, etc., during periods dating back to 1853 are summarized and analyzed.

The meteorological elements of the Island of Poel, based upon 25 years' observations, B. BRENDEL (*Beitr. Statis. Mecklenb., 15 (1906), No. 1, pp. 56, charts 4*).—The island and the instrumental equipment employed are described and observations on pressure, temperature, precipitation, humidity, cloudiness, wind movement, etc., are summarized in tables and charts.

On the amount and origin of the ammonia in the products of the eruption of Vesuvius in April, 1906, J. STOKLASA (*Ber. Deut. Chem. Gesell., 39 (1906), No. 13, pp. 3530-3537; abs. in Chem. Abs., 1 (1907), No. 2, p. 160*).—The author reports the finding of ammonia and ammonium compounds in the gases and in the ashes and lava ejected from the crater, ammonium chlorid in some cases constituting 75 per cent of the water-soluble portion of the lavas and 33

per cent of the water-soluble portion of the lapilli. The ashes, however, yielded very small amounts of this compound. It is believed that the nitrogen is derived from nitrids.

Hail, E. SCHARF (*Der Hagel. Halle: Author, 1906, pp. VI+195, pls. 27, figs. 13; rev. in Ztschr. Landw. Versuchsw. Österr., 9 (1906), No. 11, p. 1917*).—This book discusses in a simple way the character of hail, but especially the injury which it does to different kinds of crops at various stages of growth.

Notes on water softening, W. D. COLLINS (*Engin. Rec., 55 (1907), No. 7, pp. 173-175*).—The author describes simple methods which can be used "by an engineer or other person without chemical training" for determining the treatment necessary to soften a hard water. These methods are practically the same as those recommended by the committee on standard methods of the American Public Health Association (E. S. R., 17, p. 331).

The purification of muddy waters, A. GAUDUCHEAU (*Bul. Écon. Indo-Chine, n. ser., 9 (1906), No. 59, pp. 1174-1187, figs. 2*).—A method of treatment with potassium permanganate, precipitation with iron salts, and filtration, which is claimed to be efficient, is described.

Purification of municipal water supplies, G. S. WILLIAMS (*Rpt. Mich. Acad. Sci., 8 (1906), pp. 122-127*).—This article briefly describes and discusses the efficiency of the slow sand and the mechanical or chemical method of filtration for the purification of water. The former is considered the safer method. The latter, however, gives good results in competent hands.

Ideals concerning municipal water supplies, I. C. RUSSELL (*Rpt. Mich. Acad. Sci., 8 (1906), pp. 128-136*).—Waters from deep sources are considered the safest, but these may become contaminated with disease-producing germs by exposure to the air. Surface waters and shallow wells are generally to be viewed with suspicion even when all practicable means have been employed to prevent contamination.

"In order to reduce the danger of surface water becoming unwholesome, every household, every community, every city, every factory, every slaughterhouse, etc., should be required to destroy or render harmless and unobjectionable its own refuse, before it is permitted to enter streams or other surface water bodies, and also before it is distributed in such a manner as to be dangerous or annoying through the action of the wind or in other ways."

The copper sulphate treatment of water supplies, K. F. KELLERMAN (*Surveyor, 31 (1907), No. 786, pp. 224, 236*).—This is an abstract of a paper on this subject read before the Biological Society of Washington, pointing out the efficiency of this method of treatment, but insisting that it should be considered at present as an emergency treatment and applied only under expert supervision.

The futility of a sanitary water analysis as a test of potability, M. O. LEIGHTON (*Biological Studies by the Pupils of William Thompson Sedgwick, Boston, 1906, pp. 36-53*).—In this article it is contended that the ordinary sanitary analysis is not a reliable means of distinguishing between a dangerous and a wholesome water, and that "the conventional method of seeking for evidences of pollution by sanitary analyses, or of accepting or rejecting a water upon such evidence, is in its broad and essential features quite misleading, too frequently dishonest, and in some cases absurd. . . . The term 'sanitary analysis' as used in this discussion does not include tests for specific organisms."

On the hygiene of drinking water, SMALAKIES (*Illus. Landw. Ztg., 27 (1907), No. 3, pp. 13-16*).—The judging of the hygienic quality of the drinking water on the basis of physical and chemical analysis is discussed and the results of examinations of 525 samples of drinking water from 201 farms are summarized.

Bacteria of the dairy wells in the vicinity of Washington, D. C., and their possible relation to typhoid fever at Washington, K. F. KELLERMAN and T. D. BECKWITH (*Engin. News*, 57 (1907), No. 6, p. 152, fig. 1).—This is a paper read at the New York meeting of the Society of American Bacteriologists December 29, 1906. The authors conclude as a result of their examination of a few dairies (especially the water supply) in the neighborhood of Washington, that "it would seem highly probable that, under the conditions portrayed, much of the typhoid of the city of Washington may be ascribed either directly or indirectly to the unsanitary dairy farms."

Shall pollution of Michigan streams be permitted? M. O. LEIGHTON (*Rpt. Mich. Acad. Sci.*, 8 (1906), pp. 119-121).—Assuming that the streams of Michigan must inevitably be polluted, the author attempts to draw a definite line between permissible and unavoidable pollution and unreasonable or gross pollution.

Prevention of the bacterial contamination of streams and oyster beds, W. P. DIGBY and H. C. H. SIENTON (*Surveyor*, 30 (1906), Nos. 777, pp. 653-655; 778, pp. 685-690).—This article deals with progress which has been made in methods of sewage treatment since the exhaustive report of the Royal Commission on this subject (E. S. R., 16, p. 1032). It is asserted that methods of sewage treatment have now been devised by which "within reasonable limits of cost the dangerous qualities of the sewage may be wholly eliminated." The hypochlorite method is considered especially efficient for this purpose and its application and cost are discussed in some detail.

Public water supplies, sewage disposal, and stream pollution (*Ann. Rpt. Bd. Health Ohio*, 20 (1905), pp. 61-220, 223-297).—The systems followed in a large number of Ohio towns are briefly described and discussed, with results of examinations of a large number of samples of water proposed as public water supplies.

Farming for sewage purification, J. D. BROWN (*Surveyor*, 31 (1907), No. 785, p. 196).—The method followed at Consett, England, is briefly described. The sewage is applied mainly to fallow land, but also to soil on which hay and vegetables are grown. The purest effluents are obtained from cropped soil and from soil which has received sewage for some time.

SOILS—FERTILIZERS.

Soils; how to handle and improve them, S. W. FLETCHER (*New York: Doubleday, Page & Co., 1907, pp. XXVIII + 438, pt. 1, figs. 114*).—This is the third volume of the Farm Library series and attempts "to set forth the important facts about the soil in a plain and untechnical manner." Different chapters treat of soil builders; the nature of soils; the kinds of soils and how to manage them; soil water, the benefits of tillage; the objects and methods of plowing; harrowing and cultivating; rolling, planking, and hoeing; the drainage of farm soils; farm irrigation; maintaining the fertility of the soil; green-manuring and worn-out soils; farm manures; and commercial fertilizers.

The soils of Iowa, W. H. STEVENSON (*Farming*, 3 (1907), No. 1, pp. 16, 17, figs. 1).—The typical soil areas of the State are briefly described.

On moor culture, H. VON FEILTZEN (*Fyra Uppsalser i Växtkultur. Gothenburg, 1906, pp. 1-41*).—Practical advice is given in regard to the culture of moor soils, with a résumé of the results of recent experiments conducted at Jönköping Moor Culture Station.

The sand dunes of the desert of Islay (*Ann. Astron. Observ. Harvard Col.*, 39 (1906), pt. 2, pp. 287-292, figs. 2).—Observations on the formation and movement of these dunes are briefly discussed.

The decomposition of the feldspars, A. S. CUSHMAN and P. HUBBARD (*U. S. Dept. Agr., Office Pub. Roads Bul. 28, pp. 29, figs. 6*).—This bulletin deals with studies of mechanical, physical, and chemical factors which modify the decomposition of feldspars, the results of which are thus summarized:

“(1) Water acts immediately upon finely powdered feldspars, as can be shown by an indicator, such as phenol phthalein. The reaction does not proceed far, owing to the clogging of the unremoved decomposition products.

“(2) The soluble alkaline bases set free by the decomposition are prevented from passing into solution by absorption.

“(3) The decomposition reactions can be made to go further by mechanical abrasion in the presence of water, by treatment with dilute solutions of certain electrolytes and by electrolysis.

“(4) The decomposition of ground feldspar can be made practically complete in the laboratory by properly combining these modifying factors.”

The views regarding the mechanism of the decomposition reactions presented in previous publications (*E. S. R., 17, pp. 301, 598*) were confirmed in these later investigations.

It is stated that “the fundamental principles of the extraction of potash from finely ground feldspathic rocks by process of electrolysis, either with or without the addition of an acid to the anode chamber, have been made the basis for an application for a United States patent, so that the method may be used by the Government of the United States or any of its officers or employees in the prosecution of work for the United States, or by any person in the United States without the payment of royalty.”

Experiments to determine the available phosphoric acid in soils, O. HOFMAN-BANG (*K. Landbr. Akad. Handl. och Tidskr., 45 (1906), No. 3-4, pp. 316-333*).—Fertilizer trials with wheat, barley, beans, and mustard were made by the author during 1902-1905, and the amounts of phosphoric acid contained in the harvested crops compared with those extracted by different solvents recommended in soil analysis, as follows: Hydrochloric acid, sp. gr. 1.12, digestion for 3 hours on a water bath; hydrochloric acid, sp. gr. 1.019, digestion for 48 hours at room temperature; 2 per cent acetic acid, 48 hours' digestion; 2 per cent citric acid, digestion at room temperature for either 48 hours or 7 days.

The soil experimented with was a calcareous soil, containing 0.260 per cent total nitrogen. The following mineral components were extracted therefrom by the first solvent given: K_2O 0.33 per cent, P_2O_5 0.8 per cent, CaO 0.75 per cent, MgO 0.54 per cent, F_2O_3 3.22 per cent, Al_2O_3 3.88 per cent, and SiO_2 0.23 per cent. The results given go to show that for the soil experimented with, and very likely for soils of similar composition, digestion with 2 per cent acetic acid gives the most satisfactory indication of the content of phosphoric acid in the soil that is immediately available for plant growth.—E. W. WOLL.

Acid soils, A. L. KNISELY (*Oregon Sta. Bul. 90, pp. 23*).—This bulletin summarizes the replies made by 80 farmers in different parts of Oregon to a circular of inquiry sent out by the station regarding the character of the soil of their farms, the principal crops grown, the principal wild grasses and weeds, and the reaction of the soil as determined by the litmus paper test.

Of the 80 tests of soil for acidity made and reported by farmers, 10 per cent showed no acidity, 35 per cent very little acidity, 38.75 per cent considerable acidity, and 16.25 per cent strongly acid. The majority of the extremely acid soils examined in these tests were dark loam, muck, beaver dam or peat, which usually are rather poorly drained. “In a few cases upland sandy, gravelly clay loams have been found to be very acid. A majority of the sandy and clay loams examined possess a considerable degree of acidity.

"Plantain and sorrel were found to be more common than other weeds on soil containing considerable or very much acid. These weeds were also quite common on soils containing little or no acid.

"Acids in the soil are difficult to leach out. Acid soils may be improved by applications of quicklime, air-slaked lime, or wood ashes. The more thoroughly lime is incorporated with the soil the more effective will be its action on crop production."

Results of experiments on the liming of soils, H. J. PATTERSON (*Maryland Sta. Bul. 110, pp. 56*).—These experiments were a continuation of those previously reported in Bulletins 56 and 66 of the station (E. S. R., 12, p. 624). In addition to the results of the experiments, the bulletin gives some general information on liming soils and on the composition of lime and limestone.

The results of the experiments reported show that in a rotation of corn, wheat, and timothy and clover on run-down sandy loam naturally well drained, the limed plat gave larger yields than the unlimed plat, the average net return being \$4.50 per acre annually; that an application of 20 bu. of lime gave only about 25 per cent more net profit than an application of 10 bu., and of 60 bu. only about 50 per cent more than 10 bu., the relative profits at the end of 4 years being in favor of 20 bu. per acre; and that on unproductive, stiff, wet, clay soil it is decidedly advantageous to use lime in combination with green manures (cowpeas) and stable manure.

The experiments on methods of applying lime and on the relative value of different forms of this material gave results slightly in favor of incorporating the lime with the soil before slaking and immediately upon application rather than using it as a top-dressing.

Oyster-shell lime was apparently somewhat more effective than stone lime, though the difference was not marked. Magnesian lime produced decidedly better yields of grain than the pure lime, though not quite so much forage.

In comparative tests barium oxid gave results very similar to those obtained with lime, indicating that the effect of lime is more largely due to chemical and physical action in the soil than to furnishing plant food.

Calcium carbonate gave decidedly better results than caustic lime, and the application of shell marl produced more grain and forage than either stone lime or oyster-shell lime. Caustic lime was cheaper and much more effective than gypsum. The same was true of finely ground oyster shells. Caustic lime was much more effective than gas lime of oyster-shell origin. Calcium phosphate in the form of finely ground raw phosphate rock gave better results than gypsum, but not so good as either carbonate or caustic lime. Soft-coal ashes produced little, if any, effect.

Lysimeter experiments, C. F. ECKART (*Hawaiian Sugar Planters' Sta., Div. Agr. and Chem. Bul. 19, pp. 31*).—This bulletin reports two series of experiments made with tub lysimeters described in previous publications of the station (E. S. R., 14, p. 554), the first to study the behavior of various nitrogenous fertilizers when applied to the station soil, the second to note the effect on the same soil of heavy applications of burnt lime, ground coral, and gypsum, with special reference to the rate of nitrification and the amounts of lime, potash, and phosphoric acid removed in the drainage under liberal irrigation.

First series (pp. 5-19).—In the first series of experiments nitrogen was applied in the form of tankage, fish scrap, hoof meal, nitrate of soda, sulphate of ammonia, and dried blood in amounts furnishing 1 gm. of nitrogen to each pound of dry matter in the soil. The soils in the lysimeters were irrigated first at weekly intervals and subsequently at biweekly intervals, the drainage being collected in galvanized iron containers and subjected to analysis. The largest

amount of water applied at any one time was at the first irrigation, which amounted to 2.91 in. In the three irrigations which followed 1.47 in. was applied, subsequent irrigations being 2.2 in. each.

The following table gives the results of determinations of nitric nitrogen in the drainage water of the different lysimeters expressed in percentages of the original amount of nitrogen applied to each lysimeter, namely, 16.3 gm.

Nitric nitrogen in drainage for different periods.

[Percentage of nitrogen added to soil.]

Period and date.	Tankage.	Fish serap.	Hoof meal.	Nitrate of soda.	Sulphate of ammonia.	Dried blood.
Period 1, Mar. 14-Apr. 4.....	4.64	0.66	0.72	85.50	1.53	0.73
Period 2, Apr. 4-May 31.....	2.47	4.59	8.37	2.62	36.74	5.70
Period 3, May 31-July 25.....	4.26	9.91	18.07	.82	30.00	14.14
Period 4, July 25-Sept. 19.....	2.94	8.40	7.65	.94	5.91	10.21
Period 5, Sept. 19-Nov. 21.....	3.53	4.51	3.63	.54	1.40	2.89
Total.....	17.84	26.75	38.44	90.42	75.58	33.67

As will be noted, the amounts of nitrogen recovered as nitrate in the drainage water varied from 90.42 per cent in the case of nitrate of soda to 17.84 per cent in the case of tankage during a period of practically 8 months. It will also be observed that the nitrate of soda passed into the drainage water quite rapidly, 85.5 per cent being so recovered in the first period. The sulphate of ammonia was more slowly recovered and does not appear in large amounts as nitric nitrogen in the drainage until the second and third periods, but as a rule precedes in this respect the organic materials used. There was little evidence of any considerable amount of denitrification notwithstanding the fact that the moisture content of the soils was maintained at the high average of about 87 per cent saturation. Eight months after the various nitrogenous fertilizers were applied the drainage waters contained varying amounts of nitric nitrogen and this was as true of the nitrate of soda lysimeter as of the others.

Observations on the effect of nitrate of soda, sulphate of ammonia, and dried blood on the removal of lime from the soil showed that while soil to which none of these materials were applied lost 16.02 gm. of lime, that to which nitrate of soda was added lost 29.44 gm., 13.42 gm. of which was therefore due to the effect of the nitrate, and in the same way sulphate of ammonia was responsible for the loss of 19.58 gm. and dried blood 2.25 gm. These results with fresh water are quite contradictory to those obtained with saline water as previously reported (E. S. R., 14, p. 554).

Second series (pp. 20-31).—In the experiments with different lime compounds the materials used were applied at rates furnishing 100 gm. of lime per 100 lbs. of water-free soil; that is, at the rate of 3.92 tons per acre in case of burnt lime, 8.87 tons ground coral, and 11.08 tons of gypsum.

Examinations of the drainage water show that there was an approximate decrease of nitric nitrogen per acre of 1.69 lbs. in case of burnt lime, a gain of 3.1 lbs. in case of ground coral, and a decrease of 7.54 lbs. in case of gypsum as compared with the amount found in drainage of untreated soil. Calculated on the basis of gain or loss per ton of material, the figures are a decrease of 1.66 lbs. in case of burnt lime, a gain of 1.35 lbs. in case of ground coral, and a decrease of 2.61 lbs. in case of gypsum. The prejudicial effect on nitrification of the quicklime is attributed to excessive alkalinity produced by the use of this material. "The deleterious action of gypsum in this particular is, in the opinion of the writer, an indirect one, and was caused by the large amounts of

potash rendered soluble through displacement of that element by the lime of the gypsum."

The results reported show that an application of 472 gm. of gypsum resulted in an increase of potash in the drainage water amounting to 3.75 gm. equivalent to 198 lbs. per acre. With burnt lime only 9 lbs. per acre was removed in the drainage and there was a like loss in case of ground coral. The solubility of the phosphoric acid of the soil varied somewhat with the different forms of lime added, but the amounts were in every case very small, the largest amount being found in the drainage water of the check lysimeter, the smallest in the lysimeter to which gypsum was applied.

Note on an apparent secular change in the Rothamsted drain gages. E. J. RUSSELL (*Jour. Agr. Sci.*, 2 (1907), No. 1, pp. 29-34, fig. 1).—This article discusses a question raised by observations reported in a previous article by Miller (*E. S. R.*, 18, p. 116).

An analysis of observations with drain gages of different depth "seems to point to a secular change in the drain gages resulting in an increased evaporation of water. It is suggested that the change is brought about by the diminution of organic matter in the soil of the gages and the action of rain in washing out the finest particles."

Chemical and bacteriological soil studies, T. REMY (*Landw. Jahrb.*, 35 (1906), Sup. 4, pp. 1-62, figs. 2).—Field, pot, and laboratory experiments with two unproductive acid soils compared with one which was of good quality and of slightly alkaline reaction are reported in detail, the object of the experiments being to determine the cause of the unproductiveness of the soils. For this purpose a careful study was made of the physical, chemical, and bacteriological properties of the soils.

The general conclusions reached were that the presence of free acid, deficiency of lime, and a consequent low bacterial activity were the most pronounced characteristics of the abnormal soils, and that when these conditions were corrected the injurious effects on plant growth were removed. In these soils lime acted less as a plant food than as a neutralizer of acidity.

Methods of bacteriological investigation of soils, III, F. LÖHNIS and A. E. PARR (*Centbl. Bakt. [etc.]*, 2, Abt., 17 (1906), No. 14-16, pp. 518-528, fig. 1).—Experiments to test the putrefactive capacity of soils as described by Remy, Wohltmann, Fischer, and Schneider under different conditions of season, temperature, moisture, and food supply are reported, the general conclusion being reached that there is no such thing as a general putrefactive capacity of soils, but that this differs from time to time under the varying influence of season, temperature, and moisture content. Other investigations which bear out this conclusion are briefly reviewed.

On the occurrence and distribution of *Azotobacter chroococcum* in different soils, H. R. CHRISTENSEN (*Centbl. Bakt. [etc.]*, 2, Abt., 17 (1906), Nos. 3-4, pp. 109-119, figs. 2; 5-7, pp. 161-165, figs. 2; 11-13, pp. 378-383).—As a result of a series of studies the author concludes that the occurrence and distribution of *Azotobacter chroococcum* in different soils is determined largely by the basicity of the soil, namely, its calcium carbonate content. The growth of *Azotobacter* in a mannite and potassium phosphate solution inoculated with a definite amount of soil furnishes an index of the calcium carbonate (also magnesium carbonate) content of the soil. The test can be made more conclusive by adding to the culture solution a small amount of *Azotobacter* culture in addition to the inoculating soil.

In like manner an indication of the content of phosphoric acid easily assimilable by *Azotobacter* can be obtained by using a culture solution which contains only potassium chlorid and calcium carbonate in addition to mannite.

Azotobacter can utilize in its growth secondary calcium phosphate as well as calcium salts of the organic acids, such as lactic acid and citric acid, in addition to calcium carbonate, but it can not utilize in this way tribasic calcium phosphate, calcium chlorid, and calcium sulphate. Thomas slag as well as secondary calcium phosphates are easily assimilated by *Azotobacter*, while iron and aluminum phosphates, bone ash and raw phosphates, and bone meal are almost unassimilable. The author believes that these facts encourage the hope that it may be possible to work out a biological method for determining in a general way the available plant food of soils.

The author's experiments show very positively that a certain amount of phosphoric acid and also of lime in the soil is an essential condition to the decomposition of mannite. He reports experiments with a soil which had been continuously fertilized for 12 years with nitrate of soda without liming and in this way exhausted of phosphoric acid, which when used to inoculate a culture solution of mannite, calcium carbonate, and potassium chlorid gave no reduction of mannite.

The author urges great care in the taking of samples for the determination of the occurrence and distribution of *Azotobacter* to prevent foreign infection, and points out that it is necessary to inoculate the solutions as quickly after the taking of the sample as possible. However, for biological reactions relating to the lime and phosphoric acid content such precautions are not of so much importance.

Some observations on the assimilation of atmospheric nitrogen by a free living soil organism—*Azotobacter chroococcum* of Beijerinck, S. F. ASHBY (*Jour. Agr. Sci.*, 2 (1907), No. 1, pp. 35-51).—This article reviews briefly the history of investigations on nitrogen fixation, describes the preparation of cultures of *Azotobacter chroococcum* and the appearance of this organism, and reports tests of the rate of fixation of nitrogen by pure and impure cultures of this organism obtained from soil from Mombasa, East Africa; Cairo, Egypt, and Rothamsted, as well as in culture solutions inoculated with soil from different sources, some of which contained *Azotobacter*, and others were free from the organism.

The rate of fixation in pure cultures varied from less than 5 to more than 7 mg. of nitrogen for each milligram of carbohydrate used, the rate of fixation being apparently somewhat greater in the case of mannite than of glucose.

In the experiments in which the culture solutions were inoculated with soils from different sources the rate of fixation was 6.95 mg. of nitrogen for each gram of mannite in case of the soils containing *Azotobacter* and 3.22 mg. in case of soils which did not contain the organism.

The author states as conditions favorable for fixation of nitrogen (1) an abundant supply of air, (2) the presence of a base—calcium carbonate or, preferably, according to the author's investigations, magnesium carbonate, which not only more effectually neutralizes acidity due to foreign organisms in the early stages of culture, but also prevents butyric fermentation. The magnesium carbonate delays the development of the nitrogen-fixing organism somewhat, but the final yield of nitrogen is larger than with calcium carbonate.

The organism obtained from East African soils was in every way similar to that obtained from Rothamsted soil, except that fixation with it was more rapid and greater. It also possessed the property of turning brown and finally black with age, even in pure cultures.

It was observed that while *Azotobacter chroococcum* produces no spores, yet it can resist drying up in the air for a long time. "Old cultures of the organism on agar which had dried down to a leathery consistency after many months still showed abundant growth after pouring a fresh culture solution over them.

It is evident then that the organism can be freely distributed in dust by the wind."

A bibliography of 13 references to investigations on this subject is given.

On nitrogen bacteria, H. FISCHER (*Verhandl. Naturhist. Ver. Preuss. Rheinlande*, 62 (1905), pt. 2, pp. 135-145, pl. 1).—A study of the microscopic characteristics and behavior in cultures of different forms of *Azotobacter* is briefly reported and illustrated with several reproductions of microphotographs.

Can fungi fix the free nitrogen of the air and increase the total nitrogen of the soil? B. HEINZE (*Ann. Mycol.*, 4 (1906), No. 1, pp. 41-63; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 17 (1906), No. 8-10, pp. 266, 267).—The author shows that in addition to *Azotobacter* and *Clostridium*-like organisms there are many other organisms which fix nitrogen, as for example, blue-green algae, which, however, have a lower fixing capacity than *Azotobacter*. Whether molds have the power of direct fixation is still questionable. Like the algae, however, they aid the nitrogen-fixing organisms by supplying necessary carbonaceous food.

The formation of hydrocarbons of the acetylene series was observed in cultures of *Azotobacter*. In the fixation of nitrogen the first assimilation products are thought to be amino acids and the second probably salts of carbamin acid. From the high molecular amino acids the protein compounds may be gradually built up.

Studies on nitrogen fixation in cultivated soils, P. SCHNEIDER (*Landw. Jahrb.*, 35 (1906), Sup. 4, pp. 63-83, fig. 1).—A series of culture and pot experiments with nitrogen-fixing bacteria (*Azotobacter*, etc.) and root tubercle organisms (horse-bean bacteria and pure cultures for peas prepared by this Department) in various media is reported.

The conclusions reached from these investigations are that nitrogen-collecting bacteria can fix amounts of nitrogen in the soil which are capable of being determined by analytical methods. This fixation is greatly increased by the addition of an organic source of energy such as mannite, glucose, etc., and is promoted by an alkaline reaction, as for example, by the presence of a suitable amount of lime. A calcareous soil is therefore especially favorable to the development of nitrogen-collecting organisms. The fixation of nitrogen can be very appreciably increased by the addition of potassium phosphate. Loose texture of the soil, permitting good aeration, also increases it. Root tubercle bacteria which had been grown on powdered chalk were more active as inoculating material than those which had been grown on gelatin.

Some observations on nitrification, S. F. ASHBY (*Jour. Agr. Sci.*, 2 (1907), No. 1, pp. 52-67).—A series of observations on substitution of other bases, ferric hydrate and iron rust, for calcium carbonate; nitrification of ammonia absorbed by clay and peat; direct nitrification of a neutral ammonium salt; and the influences of ammonium salts and asparagin upon the oxidation of nitrites to nitrates by *Nitrobacter*, is reported, the results leading to the following conclusions:

"Carbonates are not the only substances in the soil which serve as bases for nitrification, since a marked nitrification of an ammonium salt can be brought about in the presence of ferric hydrate, either in the freshly precipitated state or as 'iron rust.' In solutions nitrification is not completed with this substance, probably because the ferric nitrite or nitrate formed dissociates and the solution becomes acid.

"Neither kaolin nor modeling clay serves as a base for nitrification.

"The double ammonium combination formed by the absorption of ammonium salts by modeling clay can most probably be nitrified in the absence of any base, but the corresponding combination with peat undergoes no nitrification in the absence of a base.

"The function of the base in nitrification is to form ammonium carbonate, which is alone directly nitrifiable, and the facility with which nitrification is set up by different carbonates depends upon the rapidity with which they can react with a neutral ammonium salt to produce ammonium carbonate. This reaction is greater with magnesium carbonate than with calcium carbonate, but is almost absent with copper carbonate, a result which is not due to a poisonous action on the organism.

"Ammonium salts and asparagin inhibit the oxidation by *Nitrobacter* of nitrites to nitrates, but this action can be largely obviated by (a) abundant inoculation of the organism, (b) allowing the organism to multiply before addition of the ammonium salt or asparagin, (c) inoculating with an organism which has become habituated in previous culture to ammonium salts or asparagin by gradually increasing the concentration of the latter substances."

On a new denitrifying bacterium isolated from goat manure, J. HOHL (*Landw. Jahrb. Schweiz*, 20 (1906), No. 9, pp. 510-514).—The microscopic characteristics and behavior under various culture conditions of this organism, to which the name *Bacillus denitrificans fluorescens* γ is given, are described. The organism is believed to be distinct from that described by Christensen under the name of *Bacillus denitrificans fluorescens* α .

Seed and soil inoculation, J. M. HAYMAN (*Rpt. Cawnpore [India] Agr. Sta.*, 1906, pp. 29, 30).—Tests of Moore's method of inoculation on gram are briefly reported. Inoculation had little appreciable effect on the crop, even on soil which was supposed to be free from the organisms peculiar to this plant. This is thought to have been due to the fact that leguminous plants of all kinds grow freely throughout the region without artificial inoculation.

Soil inoculation (*Queensland Agr. Jour.*, 17 (1906), No. 6, pp. 271-273).—This is a brief discussion of the utilization of nitrogen of the air by means of soil inoculation as described in publications of this Department and by electrical fixation as practiced in Norway by the Birkeland and Eyde process.

Soil inoculation for leguminosæ (*Country Life [London]*, 21 (1907), No. 526, p. 174).—Directions for use of pure cultures in inoculating seed, soil, and growing crops, and statements regarding the success of such inoculation in practical tests in England, Scotland, and Ireland are quoted from a circular prepared by Professor Bottomley, of Kings College.

The industrial fixation of atmospheric nitrogen, G. L. RAGONDET (*Ann. Gembloux*, 16 (1906), No. 12, pp. 659-690, figs. 2).—A rather complete summary of present knowledge relating to the fixation of atmospheric nitrogen in the form of calcium cyanamid and nitrates and nitrites, and the agricultural uses of these materials, is given.

The fixation of atmospheric nitrogen by electro-chemical means, H. INGLE and I. B. POLE EVANS (*Transvaal Agr. Jour.*, 5 (1906) No. 17, pp. 137-139).—This is a review of an address before the Society of Chemical Industry by P. A. Guye, already noted (*E. S. R.*, 18, p. 218).

An arrangement of electrodes for electric ovens for treating gases, K. BIRKELAND and S. EYDE (*Norwegian Patent No. 15,706*, Oct. 23, 1905; *abs. in Chem. Ztg.*, 30 (1906), No. 104, *Reperit.* No. 57, p. 475, fig. 1).—A water-cooled electrode is described.

Utilization of atmospheric nitrogen for agricultural purposes (*West Indian Bul.*, 7 (1906), No. 3, pp. 237-250).—This is a review of recent literature on this subject taken largely from Experiment Station Record and annual reports of the Chemical Society of London.

What is the practical value of the new nitrogen fertilizers as shown by the experiments already made? T. ALEXANDER (*Separate from Wiener Landw.*

Ztg., 1906, No. 94, pp. 10).—Various experiments with lime niter, lime nitrogen, etc., in comparison with ammonium sulphate and nitrate of soda are reviewed, showing that while these newer products are not equal to nitrate of soda in fertilizing effect they show a high degree of efficiency as fertilizers and can now be made at prices which will make them a factor in regulating the price of nitrate of soda, this being especially true in case of the lime niter.

On the future supply of combined nitrogen, S. ZEISEL (*Wiener Landw. Ztg.*, 1906, Apr.; *abs. in Staz. Sper. Agr. Ital.*, 39 (1906), No. 6-7, pp. 623-629).—This article discusses the possibilities of the natural deposits and of the various methods of artificial preparation of nitrogen compounds.

Pot experiments on the action of lime nitrogen, A. STUTZER (*Landw. Vers. Stat.*, 65 (1906), No. 3-4, pp. 275-282; *abs. in Jour. Chem. Soc. [London]*, 92 (1907), No. 531, II, p. 48).—The literature of fertilizer experiments with lime nitrogen is reviewed and pot experiments carried out by the author are briefly reported.

In pot experiments with rye followed by three crops of mustard in succession without further manuring the lime nitrogen gave nearly as good results as nitrogen in ammonium sulphate and better than that of sodium nitrate, the low results with the latter being attributed to leaching.

The technical problem of nitrates, G. HOSTELET (*Rev. Écon. Internat.*, 4 (1906), No. 3, pp. 620-630).—The world's supply of nitrates and the possibility of increasing this supply by artificial means are discussed.

The artificial production of nitrate of lime, J. B. C. KERSLAW (*Sci. Prog. Twentieth Cent.*, 1 (1906), No. 2, pp. 361-364).—A brief account is given of the progress which has been made in electrical fixation of the nitrogen of the air.

Fall application of nitrate of soda, P. PIPERS (*Rev. Gén. Agron., n. ser.*, 1 (1906), No. 8, pp. 325-339).—Cooperative plot experiments with rye, wheat, oats, potatoes, beets, and clover, to test the advisability of applying nitrate of soda in the fall are briefly reported.

The general conclusions reached were that a small application of nitrate of soda is indispensable for cereals on soils poor in nitrogen, such application insuring a profitable return. Small applications of nitrate in the fall are also recommended on good soils when the seeding is late. In this case, even though there may not be a direct benefit, the necessary expenditure is advisable as an insurance against winter injury.

The production of ammonium sulphate in Italy, C. MONTANARI (*Staz. Sper. Agr. Ital.*, 39 (1906), No. 6-7, pp. 610-617).—Statistics on this subject are briefly summarized.

The manufacture of superphosphate, C. ELSCHNER (*Amer. Fert.*, 25 (1906), No. 5, pp. 5, 6, fig. 1).—This article discusses especially European methods of recovering and utilizing the fluorin gases driven off in the preparation of superphosphates.

A process for preparing easily soluble compounds of phosphoric acid and silicic acid, W. WOLTERS (*German Patent No. 170,353*; *abs. in Ztschr. Angew. Chem.*, 20 (1907), No. 1, p. 32).—The process consists of fusing raw phosphates with lime and artificial silicates and rapidly cooling the fused mass with cold water or by throwing it upon cooled metal plates. It is claimed that by this means the phosphoric acid is rendered almost completely citrate soluble. It is also claimed that the artificial silicates are better adapted to the process and yield a product of higher citrate solubility than the natural silicates.

Investigations on the action of Wolters phosphate, A. STUTZER (*Deut. Landw. Presse*, 33 (1906), No. 93, p. 737; *Landw. Vers. Stat.*, 65 (1906), No. 3-4, pp. 283, 284).—This article briefly refers to experiments by various investigators

with this material, prepared by fusing raw phosphate with sulphate, lime, sand, and a little charcoal. Pot experiments by the author on hemp and mustard are reported, in which Wolfers phosphate gave results in every case somewhat superior in case of hemp and inferior in case of mustard to those yielded by superphosphate.

Comparative fertilizer tests with Thomas slag and agricultural phosphate, BRANDY (*Hannover, Land u. Forstw. Ztg.*, 58 (1905), p. 1226; *abs. in Centbl. Agr. Chem.*, 35 (1906), No. 11, p. 784).—Field experiments with oats, rye, and clover are reported which indicated that the Thomas slag was more effective than the agricultural phosphate (fine-ground raw phosphate).

Experiments with Thomas-ammonium phosphate, BACHMANN (*Fühlings Landw. Ztg.*, 55 (1906), No. 23, pp. 808-814).—Experiments on rye, oats, and moor meadow grasses are reported which show that the separate application of ammonium sulphate and Thomas slag gave much better results than the Thomas-ammonium-phosphate.

The stimulating effect of phosphatic fertilizers, CLAUSEN (*Illus. Landw. Ztg.*, 25 (1905), No. 35, pp. 327, 328; *abs. in Centbl. Agr. Chem.*, 35 (1906), No. 11, pp. 783, 784).—The author concludes from the results of a number of years experiments with various fertilizing materials that both Thomas slag and superphosphate exert a stimulating effect on plants, the effect of the phosphate on the young plants being more marked than that of nitrogenous fertilizers, but being observed especially in case of sandy and moor soils which are poor in phosphoric acid.

On the natural changes which manure undergoes, VAN DER ZANDE (*Deut. Landw. Tierzucht*, 1906, No. 24, p. 44; *abs. in Centbl. Agr. Chem.*, 35 (1906), No. 11, pp. 721-725).—Experiments with two well compacted heaps of strawy cow manure, each containing about 7,000 kg. of material, which lasted from June 4 to April 9 of the following year are reported.

The heaps rapidly lost in volume during the first months of the period, but the temperature was never very high, in no case exceeding 28° C. as compared with the 40 to 50° commonly observed in a fermenting heap of mixed manure.

An analysis of gas from the interior of the heap showed 22 per cent carbon dioxid and 15 per cent of marsh gas, apparently resulting from the decomposition of carbohydrates, particularly pentosans and cellulose. The principal product of the decomposition of the nitrogenous matter was ammonia, which was transformed into nitrates only on the surface of the heaps and never exceeded one-fiftieth of the total nitrogen.

Analyses of the material at the beginning and at the end of the experiment showed that there had been a loss of 20 per cent of dry matter, 7.4 per cent of nitrogen, 39 per cent of pentosans, 28 per cent of crude fiber, and 13.5 per cent of crude fat. The unusually small loss of nitrogen as compared with the 20 to 40 per cent losses reported in other experiments is attributed to the fact that unmixed manure was used and the heaps were well compacted.

The fertilizing value of poultry manure, P. LARUE (*Jour. Agr. Prat. Vit. et Écon. Rurale Midi France*, 102 (1906), No. 5, pp. 203-217).—This article contains a rather complete summary of information regarding the history of the use of such manures, factors which affect their composition, chemical composition of various kinds of manures, commercial value, preparation and application, legislation relating to their use, and a table of analyses reported by different investigators.

Wastes at salmon canneries (*Amer. Fert.*, 25 (1906), No. 5, p. 7).—This is a quotation from an argument in favor of the enactment of laws to prevent the taking of food fishes for fertilizer purposes in Alaskan waters.

Fertilizers (*Bur. of the Census [U. S.] Bul. 57, pp. 41, 42; Jour. Soc. Chem. Indus., 25 (1906), No. 23, pp. 1162, 1163*).—The statistics reported show that during 1905 the fertilizer industry followed the general tendency toward consolidation, the number of establishments reported being 400 as compared with 422 in 1900.

The capital employed rose from \$60,685,753 in 1900 to \$69,023,264 in 1905, the value of the product increasing from \$44,657,385 to \$56,632,853. The amount and value of various materials used in the manufacture of fertilizers during 1905 are stated as follows: Phosphate rock, 888,571 tons valued at \$4,244,554; potash salts, 312,600 tons valued at \$5,497,774; nitrate of potash, 1,160 tons valued at \$39,039; nitrate of soda, 42,213 tons valued at \$1,760,432; wood ashes, 17,083 bu. valued at \$2,050; acid phosphate, 320,559 tons valued at \$2,912,010; ammonium sulphate, 10,540 tons valued at \$600,856; cotton-seed meal valued at \$2,376,448; and bones, tankage, and offal valued at \$5,094,149.

Analyses of commercial fertilizers, M. B. HARDIN (*South Carolina Sta. Rpt. 1905, pp. 22-28*).—The results of inspection of fertilizers (including cotton-seed meal) during 1905 are summarized and compared with results obtained in previous years. Of the 522 samples of fertilizers examined, 13 were of a lower grade than was claimed for them.

Analyses of commercial fertilizers, M. B. HARDIN (*South Carolina Sta. Rpt. 1906, pp. 9-14*).—The results of inspection of fertilizers (including cotton-seed meal) during 1906 are summarized and compared with results obtained in previous years. Of the 506 samples of commercial fertilizers examined, 412 were of the grade claimed for them, 81 were of a higher grade, and 13 of a lower grade.

Commercial fertilizers in 1905-6, G. S. FRAPS (*Texas Sta. Bul. 85, pp. 20*).—This bulletin gives the text of the State fertilizer law, together with information regarding taking of samples, form of tag, terms used in reporting analyses, valuation of fertilizers, fertilizers for cotton, corn, rice, and potatoes, home mixtures, fertilizer recipes, and bat guano; and reports analyses and valuations of 238 samples of fertilizers examined during the season. It is reported that the amount of commercial fertilizers used in Texas is comparatively small, amounting to only 13,500 tons in 1905-6.

Commercial fertilizers, J. H. STEWART and B. H. HITE (*West Virginia Sta. Bul. 108, pp. 355-448*).—This is a complete report of fertilizer inspection in West Virginia during the year 1906, and gives guaranteed and actual analyses of 336 samples of fertilizers offered for sale in the State during that year.

Approximate unit cost of constituents of fertilizers and feeding stuffs (*Mark Lane Express, 96 (1907), No. 3928, p. 10*).—Schedules of trade values of the principal constituents of fertilizers and feeding stuffs in Great Britain are given and their use in calculating the value of these materials is explained.

The mineral industry during 1905: Its statistics, technology, and trade, edited by W. R. INGALLS (*New York and London: Engin. and Min. Jour., 1906, vol. 14, pp. 728; rev. in Jour. Soc. Chem. Indus., 25 (1906), No. 22, p. 1123*).—Among the materials of special agricultural importance for which statistics are given are phosphate rock, potassium salts, gypsum, and limestone.

AGRICULTURAL BOTANY.

Report of the department of botanical research, D. T. MACDOUGAL (*Carnegie Inst. Washington Year Book, 5 (1906), pp. 119-139, pls. 5, fig. 1*).—An account is given of the investigations being carried on at the botanical research laboratory, Tucson, Ariz., under a grant from the Carnegie Institution. The

facilities of this laboratory, known as the Desert Botanical Laboratory, are described, together with some of the investigations in progress. These include studies on the influence of altitude and climatic factors upon vegetation—acclimatization, movements, and distribution of desert vegetation, studies on transpiration, root habits of plants, soil and air temperatures, etc.

Report of the department of experimental evolution, Cold Spring Harbor, New York, C. B. DAVENPORT (*Carnegie Inst. Washington Year Book*, 5 (1906), pp. 92-105, pls. 3, fig. 1).—An account of the investigations in progress under the Carnegie Foundation at the laboratory of experimental evolution, Cold Spring Harbor, New York. Among the principal subjects are the inheritance of characteristics, unit characteristics, rôle of selection, origin of new characteristics, and identity of evolutionary processes in plants and animals.

The author states that the policy of the laboratory is not to seek after practical results, but to confine the investigations to a study of the laws of evolution and the various principles underlying them. After describing the equipment of the laboratory, brief preliminary reports are given on a number of the investigations.

Elementary species in agriculture, H. DE VRIES (*Separate from Proc. Amer. Phil. Soc.*, 45 (1906), pp. 149-156).—In a paper presented before the Philosophical Society the author discusses the relative merits of plant breeding by the selection of unit characters and by the method pursued by some breeders wherein the resultant crop is secured by a prolonged system of elimination. He claims that selection by individual seed is much more successful than where the selection is made of a number of individuals, which must necessarily include some that are not pure races. Incidentally the author calls attention to the fact that the breeding experiments carried on by N. H. Nilsson and W. M. Hays corroborate his theory of evolution by mutation.

The existence of a semipermeable membrane inclosing the seeds of some Gramineæ, A. J. BROWN (*Ann. Bot. [London]*, 21 (1907), No. 81, pp. 79-87).—While investigating the conditions governing the absorption of water by the ripe grains of certain cereals, the author made some experiments with the grain of a variety of barley, which indicated that the embryo and endosperm of this grain are contained within a semipermeable covering.

A number of experiments were carried on to test the permeability of this membrane to water, iodine solution, and various salt solutions, and it was found that the embryo and endosperm are inclosed within an envelope through which water and iodine readily pass to the interior of the grain, but acids and salt solutions are retarded. To test whether this envelope of the barley grain was due to living protoplasm or not, seeds were treated with boiling water, after which they were placed in a normal sulphuric-acid solution for 48 hours. Subsequent investigation showed that there was no penetration by the acid, indicating that the semipermeable property of the covering of the grain is not due to the action of living protoplasm. It seems probable that this property centers in the testa, but whether the property is confined to only one of the layers has not been definitely determined.

Experiments with oats, wheat, and rye showed that they all possess a similar semipermeable covering.

The culture of the excised embryos of barley on nutrient solutions containing nitrogen in different forms (*Trans. Guinness Research Lab.*, 1 (1906), pt. 2, pp. 288-299).—Embryos of barley excised after germination were grown on different nutrient solutions containing a number of forms of nitrogen to determine the value of nitrogen as a nutrient for these plants.

In the experiments the actual increase in dry weight during growth, as well

as the increase in the amount of nitrogen, was determined, and in addition measurements were made of the plumules and rootlets. The forms of nitrogen employed were asparagin, aspartic acid, glutamic acid, leucin, phenylalanin, cholin, betain, allantoin, potassium nitrate, ammonium sulphate, tyrosin, and the unclassified nitrogenous substances occurring in malt, which are mainly malt peptones and malt albumoses.

The solutions containing ammonium sulphate, aspartic acid, glutamic acid, potassium nitrate, and asparagin showed progressive increases in their power to contribute nitrogen to the plant, culminating in asparagin. Asparagin appears to be the most profitable nutrient among the sources of nitrogen, just as cane sugar is among the carbohydrates.

The root development of the plantlets in water cultures was much shorter than where the plants were grown under more normal conditions, while the average length of the plumule was not affected to so great an extent.

The migration of nitrogen from the endosperm to the embryo during the limited germination occurring during the malting process (*Trans. Guinness Research Lab., 1 (1906), pt. 2, pp. 284-287*).—Studies were made to determine the transfer of nitrogen from the endosperm to the embryo during the germination occurring in malting barley.

Several varieties of barley were studied, and it was found that about 35 per cent of the endosperm nitrogen passed into the growing embryos during the 9 or 10 days' germination on the malting floors. It appears from the investigations that the permanently soluble nitrogen of malt is about double that of the corresponding amount of barley and that the insoluble proteids of the endosperm are metabolized during the malting process and brought into a condition in which they can be transferred to the embryo.

Recent investigations concerning root hairs and their secretions, F. SCHLEICHERT (*Naturw. Wechschr., 22 (1907), No. 6, pp. 91-94*).—A summary is given of recent publications relating to the morphology and biology of root hairs, the influence of the medium on their development, the chemical nature of the root-hair secretions, and the acid secretions of root hairs, fungi, etc.

A stimulus to the production of cellulose and starch, J. B. DANDENO (*Rpt. Mich. Acad. Sci., 8 (1906), pp. 40-44*).—A study is reported on the effect of black rot of apples (*Sphaeropsis malorum*) on the production of cellulose in the cell walls of the apple in the course of the decomposition of the fruit.

It appears that cellulose and starch are developed by the fungus *S. malorum* directly in the cells of the ripe apple long after its detachment from the tree. The development of the cellulose seems to be an adaptation of advantage to the fungus in enabling it to tide itself over unfavorable conditions. The apple is in a state of preservation after the fungus has acted upon it for some time, the ebony-like mummies being less subject to attacks of other fungi. The production of cellulose is the result of a stimulus upon the cell content induced by the fungus.

A botanical and a chemical study of tannins, J. DEKKER (*Bul. Kolon. Mus. Haarlem, 1906, No. 35, pp. 221*).—This publication, which is part 1 of a proposed botanical and chemical monograph of the tannins, contains an extensive bibliography of the subject, arranged in chronological order, and treats of the botany and physiology of tannins. The distribution of tannins throughout the plant kingdom is traced, the different species known to yield tannins being mentioned and notes given on their geographical distribution. Under the physiological studies the author treats of the occurrence of tannins in the plant and gives an account of their physiological significance.

The formation of hydrocyanic acid in plants, W. R. DUNSTAN and T. A.

HENRY (*Ann. Chim. et Phys.*, 8. ser., 10 (1907), Jan., pp. 118-125).—The authors summarize investigations relating to the occurrence of cyanogenetic glucosids in varieties of *Phaseolus lunatus*. The claim made by some investigators that in the Java beans and some other varieties of *P. lunatus* several distinct glucosids are to be found is in the opinion of the authors not well taken, as they believe that they are merely forms of phaseolumatin.

Concerning the distribution of hydrocyanic acid in the plant kingdom, M. GRESHOFF (*Arch. Pharm.*, 2 $\frac{1}{4}$ (1906), No. 9, pp. 665-672).—The author presented before the British Association for the Advancement of Science at the meeting in 1906 an account of the distribution of hydrocyanic acid in the plant kingdom, and the present paper gives an historical statement relating to the discovery of the various glucosids and their occurrence in various plants. Eleven different glucosids are mentioned as having been isolated, occurring in 34 families of plants represented by 86 genera and about 200 species.

Experiments with bacterial enzymes, E. O. JORDAN (*Biological Studies by the Pupils of William Thompson Sedgwick*, Boston, 1906, pp. 127-145).—The author reports studies to determine the power of certain bacterial filtrates to liquify gelatin. A number of organisms were used in this investigation, and the results of the studies are given at length.

There was found to be no evidence that the presence of gelatin in a culture medium leads to any particularly rapid or abundant production of the specific ferment acting upon the gelatin. In simple nonproteid solutions of asparagin, lactose, and mineral salts, such as sodium phosphate and magnesium sulphate, gelatinase is produced by some bacteriological species quite as abundantly, although not generally so rapidly, as in nutrient broth or gelatin.

The reaction of the culture medium is apparently without effect upon the enzym production except as it affects the conditions of bacterial growth. The gelatin-liquifying enzymes in a number of instances were found to endure heat much better in an acid than in an alkaline or a neutral medium. The enzymes were also found to withstand heat better than the bacteria producing them, and in some instances manifested their activity at temperatures considerably above the thermal death point of these bacteria.

The action of formalin in hardening gelatin cultures was found to be without diagnostic value for the separation of species, the hardening being dependent upon the stage of digestion.

FIELD CROPS.

Practical farming, E. T. SHEPHERD (*London: Crosby Lockwood & Son, 1906*, pp. VIII+154, *dgms.* 14).—This book discusses the principles of agriculture, the improvement of soils; manures and their uses in relation to crops; root, fallow, corn, leguminous, and forage crops; permanent and temporary pastures; and farm buildings.

David Dickson's system of farming (*Atlanta, Ga.: Cultivator Pub. Co., pp. 80, figs. 15*).—A popular treatise on farm management as practiced by a successful Georgia farmer. Among the more important points discussed are the general treatment of land, the fertilization of soils and crops, and the growing of corn, cotton, wheat, potatoes, turnips, and vegetables. A chapter is also devoted to fruit culture and the care of stock.

Dry farming, G. C. BAKER (*Jour. Dept. Agr. West. Aust., 14 (1906), No. 5, pp. 361-363*).—The methods of culture to be followed in order to conserve and utilize to the best advantage the soil moisture are briefly described.

Report of the associate agriculturist, C. L. NEWMAN (*South Carolina Sta. Rpt., 1906, pp. 23-25*).—A brief report on the work of the agriculturist of this

station is given with notes on experiments with cotton, corn, wheat, oats, cow-peas, and sorghums.

A marked increase in yield from the use of commercial fertilizers on marsh land, J. BECKER (*Deut. Landw. Presse*, 34 (1907), No. 7, p. 46, figs. 4).—The soil in question was a medium heavy reclaimed marsh soil which had received a dressing of barnyard manure in 1902 and had been used since then for pasturing young stock.

In 1905 a crop of oats was grown with different combinations of the following quantities of fertilizers per hectare: 900 kg. of Thomas slag, 600 kg. of kainit, 200 kg. of nitrate of soda, and 2,000 kg. of lime. With the use of all these substances together there was a net profit of 97.30 marks per hectare. When the lime was omitted the net profit was only 2.92 marks, and when any one of the other substances was omitted there was a loss in each case.

In 1906, when a crop of beans was grown, this same soil was given an application of 900 kg. of Thomas slag, 200 kg. of 40 per cent potash salt, and 70 kg. of nitrate of soda per hectare. The increase in the yield over the check test was 1,643 kg. of beans and 1,529 kg. of straw per hectare. The profit apparently due to the use of the fertilizers amounted to 240.55 marks per hectare.

The book of alfalfa, F. D. COBURN (*New York: Orange Judd Co., 1906*, pp. 336, figs. 60).—This book is a treatise on alfalfa, discussing the history, cultivation, and merits of the crop, and pointing out its uses as forage and fertilizer. Several chapters are devoted to the history, description, varieties, distribution, and productiveness of alfalfa, following which the subjects of seed and seed selection, cultivation, harvesting, and storing, and the uses of the crop for pasture, soiling, and feeding in other ways, together with its value in beef making, dairying, and other lines of animal husbandry are discussed.

A feature of the book is a chapter presenting the practical experience of alfalfa growers in 41 different States.

Agaves, their culture and use, with special consideration of Agave rigida var. sisalana, K. BRAUN (*Pflanzer*, 2 (1906), Nos. 14, pp. 209-223; 15, pp. 225-240; 16-17, pp. 241-257; 18, pp. 273-288; 19, pp. 289-304; 20, pp. 307-310).—A general discussion on the history and distribution of agaves is given and a list of specimens is described. The greater part of the article is devoted to *Agave rigida* var. *sisalana* and its climatic, soil, and cultural requirements. The commercial importance of the fiber and the methods employed in obtaining it are noted, and a bibliography of 234 references to articles and works treating of this subject is appended.

By what methods may brewing barley be improved? R. BETHGE (*Landw. Wchschr. Sachsen*, 9 (1907) Nos. 1, pp. 3, 4; 2, pp. 11, 12; 3, pp. 20, 21; 4, pp. 31, 32, *dgm.* 1).—This article discusses the improvement of barley for brewing purposes in a certain section of Saxony, which now produces brewing barley of good quality and high in yield, while from 25 to 30 years ago only small yields and a poor quality of grain were secured.

The method of carrying on the improvement work is described, the principal points sought after being given as color, form, and uniformity of kernel, yield of grain per head, fineness of glumes, high percentage of grain, small number of nodes with long upper internodes, uniform strength in germination, low protein content of grain, accurate and systematic pedigree breeding, and improved cultural methods. The work in the laboratory and the use of the plant nursery in connection with breeding barley are also discussed.

The use of potash in its relation to the quality of barley, E. WEIN (*Ztschr. Gesam. Brauw.*, 29 (1906), No. 3, pp. 26; *abs. in Centbl. Agr. Chem.*, 35 (1906), No. 12, pp. 811-815).—Experiments were conducted to determine whether

it is advantageous on the more fertile soils to use kainit or 40 per cent potash salt in growing barley and to ascertain in what quantities and at what time the application should be made to be profitable.

In 5 tests with barley and wheat on fertile clay soils a general application of superphosphate and nitrate of soda, furnishing 75 or 100 kg. of phosphoric acid and 23 kg. of nitrogen per hectare, respectively, was made, and in addition 60 kg. of potash was applied in the form of 40 per cent potash salt or of kainit. These soils ranged in calcium carbonate from 0.16 to 1.06 per cent and in potash from 0.21 to 0.48 per cent. With every test the potash apparently increased the total yield, the increase amounting to 552 kg. of grain and 522 kg. of straw per hectare. When potash was omitted the protein content of the grain increased and the starch content decreased.

A gravelly soil containing 12.40 per cent of calcium carbonate and 0.13 per cent of potash, producing potatoes and fertilized with barnyard manure the year before, received an application per hectare of 90 kg. of phosphoric acid, 15 kg. of nitrogen, and 80 kg. of potash in the forms of superphosphate, nitrate of soda, and 40 per cent potash salt or kainit, respectively. Applying the potassic fertilizer some time before sowing the barley proved beneficial, and under these conditions kainit was the more effective. The increase in the yield of grain apparently due to the potash varied from 2.7 to 4.8 per cent and that of the straw from 3.4 to 9.3 per cent.

The third test was made on a clay soil with 0.32 per cent of calcium carbonate and 0.29 per cent of potash. A general application of 90 kg. of phosphoric acid as superphosphate and 24 kg. of nitrogen as nitrate of soda was given per hectare. In addition, 40 per cent potash salt was applied in quantities furnishing 25, 50, 75, and 100 kg. of potash. The season was the third after the soil had been fertilized with barnyard manure. Only the two smaller applications of potash in this experiment were profitable.

It is pointed out that barley requires phosphoric acid, nitrogen, and potash in a readily available form and in proper proportions, and that the quantities of potash given may be relatively small if the preceding crop was fertilized with barnyard manure but that they should be correspondingly increased when 2 or 3 years have elapsed since the manure was applied. It is stated that barley responds best to the use of kainit, but that on heavy soils 40 per cent potash salt is preferred to avoid crusting of the surface.

The author refutes statements of O. Reitnair with reference to his work and points to results secured by other investigators to prove his point.

Fertilizer experiments with fodder beets, C. DUSSERRE and E. CHUARD (*Bul. Soc. Vaud. Agr. et Vit., 1907, No. 201, pp. 358-362*).—Fodder beets were fertilized at the rate of 400 kg. of 17 per cent superphosphate, 200 kg. of 48 per cent of potash, and 300 kg. of nitrate of soda per hectare, this application costing 176 francs.

The average results obtained by 17 farmers showed an increase of 16,000 kg. of beets per hectare as apparently due to the fertilizers used. The profit per hectare is given as 224 francs. The season was dry, and not all of the plant food contained in the fertilizer application was used by the crop, so that in addition to the profit secured there remained in the soil a certain quantity of the plant food supplied for the succeeding crop. The beets from the fertilized plants contained 7.46 per cent of sugar and those from the check plots 7.52 per cent.

The Williamson plan of corn culture, C. L. NEWMAN (*South Carolina Sta. Bul. 124, pp. 20*).—This bulletin contains a detailed description of the Williamson method of corn culture and reports observations made on a number of

farms on which the plan was followed. "Where the plan was strictly adhered to the yield was double or more than double that secured from nearby fields of equal soil characters and where the usual methods of corn culture were practiced."

Three different varieties of corn were found to have been used on these fields. One variety, called Williamson corn, was grown on all fields except two, one of which was planted to Marlboro Prolific and the other to a variety similar to the Williamson corn. It was noticed that with the Marlboro Prolific the size of ears and their number per stalk were apparently uninfluenced by the method of culture.

The peculiar or essential features of the Williamson plan are summarized as follows: Deep and thorough preparation of seed bed, deep planting, infrequent and partial cultivation in early stages of growth, an increase of 200 per cent or more in the number of stalks per acre, postponing application of fertilizers until corn is given its second cultivation, intentional retardation of early growth of the stalk until its size is reduced $\frac{1}{2}$ or $\frac{1}{3}$ its normal development, and following this augmented development of the ear by cultivation and heavy application of fertilizers made at appropriate intervals. The corn is planted 4 to 6 in. below the soil surface and laid by 4 to 6 in. above the level, leaving the lower 8 to 12 in. of the stalk below ground. It is suggested that the brace roots under these conditions are probably better able to perform their nutritive functions than when partly exposed.

Tillering of the corn plant, E. G. MONTGOMERY (*Lincoln: Nebr. Acad. Sci.*, pp. 35-42, pls. 4).—The tillering of corn from a botanical viewpoint is discussed and the results of experiments previously noted (E. S. R., 17, p. 657) are reported. This article includes the report of a study on the tillering capacity of six different types of kernels. From 1,600 to 2,000 kernels of each type were planted and it was found that of the kernels having large germs from 85 to 90 per cent produced tillers, while of the kernels with small germs only from 55 to 70 per cent tillered.

The production of a new variety of maize, *Zea mays* var. *pseudo-androgyna*, by traumatism and fixation, L. BLARINGHEM (*Compt. Rend. Acad. Sci. [Paris]*, 143 (1906), No. 27, pp. 1252-1254).—In a teratological study on maize the author found female flowers with the gynecium surrounded with abortive stamens, and he reports having isolated a stable variety with this abnormal characteristic, which he named *pseudo-androgyna*. The hermaphroditic character is considered purely morphological.

The new variety was derived from a plant of which the stem was cut at the base in July, 1902. The new sprout, which subsequently developed, produced a tassel with the branches covered with fertile grains. Of the 28 plants grown from this seed in 1903, 20 showed the transmission of the abnormal character of the tassel. These plants grown by themselves and protected from foreign pollen gave rise to numerous forms, among them *Zea mays praeox*. *Zea mays pseudo-androgyna* did not appear until 1904, when the hermaphroditism was discovered. In 1905, 113 individuals from seed of this form transmitted this character to 97 plants, and in 1906 the results led to the conclusion that this variation was completely fixed.

The author believes that the plant mutilated in 1902 is the origin of a family marking a period in the progress of mutation and he concludes that violent mutilations at the proper time are a very effective means of causing abrupt, hereditary, and progressive variation.

The Red Texas oats question: A statistical study, H. F. ROBERTS (*Industrialist*, 33 (1907), No. 16, pp. 243-253, figs. 5).—After Red Texas oats has been

grown in Kansas for 2 or 3 years they apparently turn to a sort having black chaff, said to be inferior in yield and quality.

A sample of this kind consisting of 39 per cent of red and 61 per cent of black hulled kernels was separated into 2 lots of 2,309 black kernels and 1,486 red kernels. These 2 lots were compared with the original mixed lot. The result showed that 138 plants of the black variety bore 966 culms and 140 plants of the red variety 1,209 culms, showing that the red variety had a greater stooing capacity in this instance than the black variety. In another similar experiment conducted at the same time but with the plants standing one in a hill 4 by 6 in. apart, 76 per cent of a total stand was secured, the 3,090 plants of the black strain producing a stand of 78 per cent and the 2,880 seeds of the red variety a stand of 74 per cent.

The habit of growth of the 2 varieties showed a marked difference, the red sort spreading the leaves and young stems flat upon the ground while the black strain sent up erect stalks. The black oats came into full head June 22 and was ripe July 15, while the red oats was fully headed on June 26 and was ripe July 21, making a growing period of 95 and 101 days for the black and the red oats, respectively. A difference in habit in the heads of the 2 sorts was also observed, the panicles of the black oats being loose and spreading while those of the red variety were much more compact. The spikelets were as a rule more firmly attached in the red than in the black oats and the chaff of the red oats wrapped the grains more closely. The individual grains with their glumes were generally shorter and plumper in the red than in the black oats, but all possible variation and intergradation in form between the 2 types occurred.

In the plant nursery a statistical study showed that 143 plants of the red oats produced 572 heads and 8,980 spikelets weighing 309.80 gm., while the same number of black oat plants produced 374 heads and 10,767 spikelets weighing 445.766 gm. This result seems to indicate that the black variety is superior to the red in every essential point except stooing capacity.

The problem as to what the appearance of the black variety is due still remains to be solved.

The effect of the correct use of nitrate of soda in growing sugar beets, H. BRIEM (*Centbl. Zuckerindus.*, 15 (1907), No. 15, p. 394).—The results of different experiments are reported and discussed with a view to showing that under proper conditions the use of nitrate of soda is not detrimental to the quality of sugar beets.

In an experiment conducted at Bonn on a sandy clay soil with a general application of 450 kg. of 16 per cent superphosphate and 200 kg. of 40 per cent potash salt per hectare, and special applications of 320 kg. and 480 kg. of nitrate of soda per hectare, there was an increase in the sugar content of the beet and in the total yield of sugar where the nitrate of soda was applied, but the heavier application did not give a profitable increase over the smaller quantity used.

The results of experiments carried on at Bernburg with the use of 300 kg. of nitrate of soda per hectare show a marked increase in the total yield of sugar as compared with the check plat, although the sugar content in the beet was reduced from 17.84 to 17.64 per cent. The use of 400, 500, and 600 kg. of nitrate of soda also showed slight reductions in the sugar content of the beet as compared with the check plat, and slight increases in the total yield of sugar as compared with the use of 300 kg. per hectare.

At Halle sugar beets were grown on sandy clay soil which had received a green manuring with peas and 40,000 kg. of barnyard manure per hectare, to-

gether with either a light or a heavy application of nitrate of soda. In both cases the use of nitrate of soda gave a profitable increase in the yield of sugar and the sugar content in the beet was also increased as compared with the check tests. In another experiment in which potash and phosphoric acid were applied instead of barnyard manure the use of the nitrate of soda also proved beneficial.

It is stated that the proper use of nitrate of soda is not injurious to the interests of the sugar manufacturer and that it often is a benefit to the farmer when the price of beets is low.

The effect of a too heavy application of nitrate of soda, H. BRIEM (*Centbl. Zuckerindus.*, 15 (1906), No. 8, p. 202).—Analyses are reported of beets grown on a sandy, humus soil and very heavily fertilized with nitrate of soda in comparison with analyses of beets grown with a normal application of fertilizers.

The relation of sodium to potash in the heavily fertilized beets was as 1:0.73, while in the normally fertilized beets it was as 1:3.88. The normally grown beets contained 0.046 per cent of sodium, while in the heavily fertilized beets this element reached 0.133 per cent. The total nitrogen content was 0.195 per cent and 0.284 per cent for the properly and improperly fertilized beets, respectively.

It is pointed out that in experiments by Hellriegel it was shown that a high sugar content is associated with a definite relation between the potash and nitrogen content of 1:1, while in these experiments the relation was as 1:3.

The occurrence of dodder on sugar beets, A. STIFT (*Bl. Zuckerrübenbau*, 14 (1907), No. 1, pp. 2-4).—The author reports the occurrence of the common dodder (*Cuscuta europaea*) on sugar beets in western Hungary.

Lectures to sugar planters (*Imp. Dept. Agr. West Indies, 1906, pp. VII+176, figs. 65*).—This publication contains lectures on the following subjects: The natural history of the sugar-cane, by D. Morris; soils and manures in relation to the cultivation of the sugar-cane, by J. P. D'Albuquerque; hints on the planting and cultivation of the sugar-cane and intermediate crops, by J. R. Bovell; the insect pests of sugar-cane and associated crops, by H. Maxwell-Lefroy; and the fungoid diseases of the sugar-cane, by A. Howard.

Report of the division of agriculture and chemistry, C. F. ECKART (*Hawaiian Sugar Planters' Sta. Rpt. 1906, pp. 21-42, figs. 6*).—A general report is here given on the work of this division for the year ending September 30, 1906. The different lines of work in progress are briefly outlined and experiments soon to be inaugurated are described.

Observations on seed-bearing sugar canes and the production of seedlings are discussed and the number of seeds of different varieties germinating and the number of plants successfully raised are given in a table. During the season 5,232 seedling canes were grown. Of 279 plants raised from West Indian seed imported in 1904, 37 have been sufficiently promising to merit special testing on the station grounds.

Tobacco culture on soils which had been reforested with *Albizia moluccana* (*Meded. Deli-Proefstat. Medan, 1 (1907), No. 2-3, pp. 61-114*).—The results of different cooperative tests indicate that reforestation with *Albizia moluccana* on the various kinds of soils under observation is not injurious to tobacco land as is commonly supposed. The method has the advantage of reducing hard soils.

The selection of seed wheat, G. W. SHAW (*California Sta. Bul. 181, pp. 149-172, figs. 12*).—This bulletin treats of the importance of seed wheat selection and describes the methods employed. A large number of samples of seed wheat were obtained over a wide area in the Sacramento and San Joaquin valleys of California for the purpose of determining the general character of

the seed used by the farmers of the State. The results secured are given in detail in tabular form. The work done at various experiment stations in selecting seed wheat is summarized.

The samples graded by the station consisted mainly of White Australian, Salt Lake Club, Bluestem, and Sonora Wheat. Comparative results of the standard, average, and poorest samples graded are given in the following table:

Comparative grading of standard, average, and poorest samples of wheat used for seed, 1904-1906.

Sample.	Grades according to size of mesh.							Weight per bushel.
	3.25 mm.	3.00 mm.	2.75 mm.	2.50 mm.	2.25 mm.	2.00 mm.	Trash.	
Salt Lake Club:	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Pounds.</i>
Standard.....	3.90	13.00	24.20	50.80	4.10	1.00	2.60	60.0
Average (2 years).....	1.66	3.92	12.09	51.17	17.14	6.13	6.26	57.0
Poorest.....	.00	.00	.85	11.34	33.50	32.13	22.16	44.5
White Australian:								
Standard.....	28.61	18.49	28.74	19.62	1.83	1.93	.75	60.5
Average (2 years).....	6.56	8.23	22.16	47.20	9.74	2.19	3.84	57.7
Poorest.....	.00	.00	.90	49.12	40.22	6.02	3.79	53.0
Bluestem:								
Standard.....	43.66	22.29	20.95	10.71	.91	.62	.83	61.0
Average (2 years).....	9.45	10.19	21.82	38.71	7.93	2.01	1.99	58.5
Poorest.....	.00	.00	.00	7.15	59.21	22.98	10.70	46.2

In general the samples showed that the quality of seed used by most farmers is lacking in purity, perfection of development, weight per bushel, freedom from weeds, and freedom from bunt. Attention is called to the fact that practically all investigators have found the use of large, plump seed of high weight per bushel the most profitable. No permanent benefit is believed to be secured from the frequent exchange of seed unless a better type of wheat or a more vigorous grain of the same type is obtained by the exchange. The most important points to be considered in seed selection are the use of seed from heavy yielding plants, a plump and heavy grain, a clean wheat, and a pure variety.

HORTICULTURE.

Japanese horticulture, N. HAYASHI (*Jour. Roy. Hort. Soc. [London], 31 (1906), pp. 18-28*).—The author outlines the history of the development of horticulture in Japan, and briefly discusses the facilities for obtaining horticultural knowledge in that country. A summary is given of over 100 kinds of fruits, vegetables, and nuts, both of native and foreign origin, now grown in Japan, with an account of the origin and economic importance of each.

Summary of results with vegetables and fruits at the North Louisiana Experiment Station from 1892 to 1907, E. J. WATSON (*Louisiana Stas. Bul. 90, pp. 47*).—The author summarizes the results of his horticultural work at the North Louisiana Station from 1892 to 1907. The subject-matter is presented under the following headings: Results with vegetables, results with fruits, and condensed information on canning fruits and vegetables.

The work for the last 3 seasons has been devoted chiefly to experiments in commercial truck growing and canning of the surplus vegetables and fruits. Tests have been made with all of the well-known vegetables, the most promising of which are discussed in detail with regard to best varieties, time of seed sowing, the average period from seed planting to marketable maturity, the yields, and prices obtained for those crops that were marketed. For several years experiments were conducted on the relative value of home-grown commercial seed (*E. S. R., 14, p. 249*).

Under results with fruits the data on variety and fertilizer tests are given, together with the period of blooming and ripening of the fruit. The author states that the data secured on fruits during the past 14 years are not very favorable since the climate is not adapted to the successful culture of many of the fruits reported upon, except to a limited extent. Condensed notes are given on the canning of fruits and vegetables, including a discussion of the advantages of home-canning, and brief remarks on the most profitable sorts for canning, including tomatoes, string beans, sweet corn, sweet potatoes, peaches, berries, and cane syrup. A homemade canning outfit is described, which can be built at a cost not exceeding \$40. A preliminary report on the experiments in truck growing and canning has been noted (E. S. R., 17, p. 364).

Tomato fertilizers at Troupe, W. S. HOTCHKISS and E. C. GREEN (*Texas Sta. Bul. 84, pp. 15, figs. 6*).—An account of fertilizer experiments and variety tests with tomatoes at the Troupe Station during the seasons of 1904 and 1905.

The fertilizer ingredients used included cottonseed meal, muriate of potash, acid phosphate, wood ashes, cow manure, nitrate of soda, lime, and tankage, either alone or in combinations. Beauty, Acme, and Earliana were the varieties tested. Tables are given showing the yield of marketable and unmarketable fruit gathered at each picking from the different fertilizers and varieties used. The experiments were conducted on soil composed of a very fine gray sand, running from 8 to 18 in. in depth and underlaid with a red clay soil.

The use of potash, either in the form of muriate of potash or wood ashes, alone or in combination, was found to be unsatisfactory. The use of large quantities of lime alone appeared to be injurious. Nitrate of soda, which was also tried in 1903, was abandoned after the 1904 experiment, as this form of nitrogen gave no better result than in the form of cotton-seed meal.

Cow manure gave fairly good results, but the largest and earliest yields were obtained from the use of acid phosphate alone on new lands comparatively rich in humus, and acid phosphate in combination with cotton-seed meal on old lands deficient in humus and fertility. For soils similar to that at the station the authors suggest the following formula: Acid phosphate 1,200 lbs. and cotton-seed meal 800 lbs., using from 400 to 600 lbs. per acre of the mixture.

Earliana produced the largest quantities of early tomatoes, and is recommended as a variety for early shipments. The authors, however, do not recommend it as compared with Acme or Beauty for a general purpose variety.

Money in cucumbers, W. DUNN (*Amer. Agr., 1907, Feb. 9, p. 166*).—The author, who is a truck grower in Craven county, North Carolina, states that he recently realized \$4,000 from 7 acres of cucumbers, which after deducting a total expense of less than \$100 an acre, left him over \$3,000 net profit.

The artichoke, R. F. LE FEUVRE (*La Alcachofa. Santiago de Chile: Inst. Agr. Chile, 1906, pp. 120, figs. 26*).—A monograph on the artichoke *Cynara scolymus*, known in this country as the Globe artichoke and valued for its edible flower heads and petals. The cardoon (*C. cardunculus*) an allied form, is classed with the artichoke in this publication.

The work includes a discussion of the origin, general importance, climatic adaptation, and cultivated varieties of the artichoke in various countries, and gives specific directions for its propagation, cultivation, and harvesting in Chile, together with the products, their uses and methods of preservation. An extensive bibliography of the artichoke is also given.

Cultivation of fruit trees, L. BUSSARD and G. DUVAL (*Arboriculture Fruitiere. Paris: J. B. Baillière & Sons, 1907, pp. 562, figs. 188*).—This volume is one of the series which constitute the agricultural encyclopedia published under the direction of G. Wery.

The book is intended as a treatise on the cultivation of tree fruits for both amateur and professional growers in France. Part 1 is introduced by chapters discussing the importance and distribution of fruit orchards in France, and a study of the morphology, anatomy, and physiology of fruit trees and their fruits. Succeeding chapters deal with all the important phases of fruit culture, including methods of propagation, the laying out, and management of different forms of fruit gardens and orchards, the preparation and fertilizing of the soil, planting, and subsequent care. This part is concluded by an extensive chapter on pruning.

Part 2 deals with each of the important species of fruit, treating of their characteristics, processes of multiplication, pruning, special requirements, harvesting, and utilization of the products. Descriptions are also given of the important varieties of each species.

Peculiar seedless apple, F. HERSE (*Naturw. Wechschr.*, 22 (1907), No. 5, p. 72, figs. 4).—A description is given of a seedless apple secured at harvest time from a country orchard in Germany, together with figures representing the external appearance of the apple and vertical and horizontal sections.

The apple is rather peculiar in appearance, since both halves appear fully and evenly developed from one side, but when turned around it is seen to be much broader at the calyx end than at the stem end. A study of the sections shows that the dividing walls of the core are absent, whereas the endocarp is present as in normal apples.

The alligator pear at Pomona, Los Angeles County, California (*Fla. Agr.*, 34 (1907), No. 6, p. 2).—This is a brief note taken from the Pomona Review, which states that an alligator pear (avocado) tree was planted from seed in Pomona some 10 years ago and has continued to thrive without special attention. During the past season 14 large pears were gathered, which sold in the Los Angeles market for \$10. The avocado is not generally considered hardy in that region.

Standard sizes of fruit boxes (*Pacific Rural Press*, 73 (1907), No. 4, p. 50).—A list is given of the standard sizes of California fruit packages for shipping purposes, including the dimensions and the amount of fruit contained in each for cherries, peaches, pears, pears for export to Europe, plums, prunes, apricots, nectarines, grapes in single crate, and grapes in double crate.

The uses of the sakoa, TRALBOUX (*Agr. Prat. Pays Chauds*, 7 (1907), No. 46, pp. 79, 89).—This is a note on the sakoa, a native fruit of Madagascar, the tree of which is said to have the appearance of an apple tree and to be very prolific. The fruit is about the size of a plum, yellowish in color, and very acid. The natives gather it from the trees in January, February, and March. The pulp is chewed by the natives to quench thirst, and is an important source of food in dry seasons when crops fail. The fruit is also utilized in making fermented beverages and in dyeing. The bark of the sakoa tree is said to be rich in tannic acid.

Pineapple culture V. History and bibliography, H. H. HUME (*Florida Sta. Rpt.*, 1906, pp. LXXIV–LXIV, figs. 3).—This is the fifth of a series of bulletins on this subject. In the 4 preceding bulletins (*E. S. R.*, 17, p. 1155) soils, varieties, results of fertilizer experiments, and the methods of harvesting, grading, packing, and shipping were discussed.

In this bulletin an account is given of the history and origin of the pineapple, together with its introduction into Europe and its early Florida history. It is said to be a native American fruit. The author mentions numerous early writers on the subject, and gives an extensive bibliography of the books, magazine articles, reports, and bulletins dealing with the pineapple.

Second note on the wild coffees of Mount Amber, Madagascar, M. DUBARD (*Agr. Prat. Pays Chauds*, 6 (1906), No. 45, pp. 518-521, figs. 2).—In the first notes on this subject (E. S. R., 16, p. 976) the author describes 3 wild varieties of coffee found on Mount Amber, Madagascar, viz. *Coffea gallienii*, *C. bonnierei*, and *C. mogeneti*. In the present note he adds further remarks on these 3 varieties and describes a new variety which he has received from Madagascar called *C. augagneuri*. This variety is said to be well characterized in the form of its leaf and the peculiarity of its fruit.

The cocoanut, P. HUBERT (*Le Cocolier. Paris: H. Dunod and E. Pinat*, 1906, pp. XIV+135, figs. 39).—Cocoanut cultivation, insect enemies, and related questions are discussed, as well as the manufacture and use of copra, desiccated cocoanut, cocoanut oil, and other cocoanut products.

The practical culture of cacao trees, A. FAUCHÈRE (*Paris: A. Challamel*, 1906, pp. 175, figs. 40).—This is a treatise on the culture and preparation of cacao for the market, with special reference to the development of the industry in Madagascar. The work is based on methods in vogue in Central America, the Antilles, Ecuador, Venezuela, Trinidad, the Guianas, Brazil, and Mexico, and deals with the natural distribution, history, species and varieties in use, climatic and soil adaptabilities, animal and insect enemies, and the important phases of culture and management.

Estimates are given of the cost of planting, cultivating, and maintaining cacao plantations both under personal supervision and by contract for a period of 10 years. The processes of fermentation, drying, and preparing the cacao fruit for the market, together with the apparatus pertaining to these processes, are discussed in full. Two appendixes are included in the work, which deal with the importance of cacao culture and special suggestions for the management of the plantation with reference to Madagascar. The work is illustrated by numerous figures.

The yucca, R. J. FOSALBA (*Bol. Agr. [San Salvador]*, 6 (1906), No. 12, pp. 579-596).—This is a reproduction of the author's report to the minister of foreign relations of Uruguay on the relative importance and uses of the yucca in the West Indies, Mexico, South America, Florida, and Java. It consists of a collection of notes on the uses and present status of the yucca industry in the different countries mentioned, together with a description of the cultivation of this plant in Cuba.

Some of the important products of the yucca are starch, alcohol, tapioca, and yucca flour. The starch is considered in Cuba to be of superior quality to all imported starches. As a flour, yucca is inferior to wheat, but is of great importance to natives of the poorer classes in the West Indies when they are unable to purchase other foods. A bibliography is given, including the various sources from which the author derived information.

The influence of cold in horticulture, A. H. PERRET (*Rev. Sci. [Paris]*, 5, ser., 7 (1907), No. 6, pp. 176-177).—The author discusses the utilization of cold storage in retarding the blooming period and the preservation of blooms of commercial flowering plants, bulbs, and shrubs. A brief account of the harvesting, grading, storing, and forcing of lilies of the valley and flowering bulbs near Hamburg, Germany, is given, together with recent experiments of M. J. Mercier, of Dijon, on the influence of cold storage in the preservation of cut flowers.

In these experiments two cold-storage mediums were used, an ice house and an artificial cold-storage room. The ice house had a temperature of about 2° C. with a relative atmospheric humidity of 90 parts per 100, while the temperature of the cold-storage room was about 5° C. with a relative humidity of 60 parts

per 100. A great variety of cut flowers were tested by being stored in vases half filled with water, and notes are given on the behavior and length of preservation of each variety. Storing in the ice house with a lower temperature and a relatively great amount of humidity gave by far the better results.

The conclusion is reached that the most suitable temperature for the storing of cut flowers is just above 0° C. (32° F.), where the active growth is checked without destroying cell life, and that the flowers should be stored in a relatively humid atmosphere in order to check the evaporation of the blooms. Careful attention, however, must be paid to ventilation, since a close, humid atmosphere is favorable to the production of molds and fungus diseases. The storage room should be dark and the leaves should be removed to reduce danger from putrefaction.

Progress in hybridization and plant culture, L. WITTMACK (*Gartenflora*, 56 (1907), Nos. 1, pp. 2-14; 2, pp. 31-37, figs. 4).—This is a paper delivered by the author before the Prussian Society for the Advancement of Horticulture, and consists essentially of a historical review of the various steps in the development of plant breeding. Concrete examples of crosses and their effects as made between different varieties of *Urtica*, four o'clocks (*Mirabilis jalapa*), Indian corn, gilly-flowers, and sweet peas are introduced in order to emphasize different phases of the discourse.

Seven gardens costing \$1,000 each, HARRIET C. BRYANT (*Country Life Amer.*, 11 (1907), No. 5, pp. 528-532, *dgms.* 7).—The author presents planting plans and specifications of 7 gardens designed for country and suburban places and intended to provide an ample supply of fruits, vegetables, and flowers, as well as attractive landscape pictures. The details and cost of each phase of construction and planting are given, together with the common and standard names, ultimate height, and the number of plants used of each variety recommended. The plans are illustrated.

The garden beautiful, W. ROBINSON (*London: John Murray, 1906, pp. 394*).—In this popular work the author emphasizes the æsthetic and artistic phases of woodland, garden, and orchard culture in the British Isles. Its aim, given in substance, is to create a greater love for the natural woodland and the more extensive use of native trees and flowers.

Numerous suggestions are made as to the planning and making of various forms of flower gardens, including Alpine, rock, wall, marsh, bog, and water gardens, the care and arrangement of house flowers, and the artistic development of fruit orchards, home woodlands, and forest plantings. Throughout the work many varieties are enumerated and discussed as to their value for these various forms of planting.

Practical suggestions for improving and beautifying rural school grounds, T. H. SCHEFFER (*Industrialist*, 33 (1907), No. 15, pp. 227-240, *fig. 1*).—Popular suggestions are made on this subject dealing with the selection of site, location of school grounds and buildings, walks, driveways, fencing, grading, and development of playgrounds, lawns, and planting of shrubs, trees, and flowers. A sample planting plan for the rural schoolhouse is also given.

The history of chrysanthemum cultivation in Japan, N. HAYASHI (*Jour., Roy. Hort. Soc. [London]*, 31 (1906), pp. 29-39, *figs. 7*).—Several forms of chrysanthemums are discussed, and descriptions are given of the successful methods of cultivating chrysanthemums as used by amateurs in Japan. The author states that the usual methods employed by nursery gardeners in Japan are very similar to those pursued in this country.

Horticulture in relation to medicine, E. M. HOLMES (*Jour. Roy. Hort. Soc. [London]*, 31 (1906), pp. 42-61, *figs. 8*).—This is a popular lecture on the use

and culture of plants for medicine, both in ancient and modern times, in which all of the important herbs employed for medicinal plants are considered. The author refers to the publications of numerous members of the medical profession who have been active in encouraging the production and cultivation of medicinal plants. A list is given of the herbs most commonly used in England for medicinal purposes.

FORESTRY.

Management of the farmer's woodlot, W. N. HUTT (*Cornell Countryman*, $\frac{1}{4}$ (1907), No. 5, pp. 128-134, figs. 3).—The author outlines the practical management of the ordinary farm woodlot for the purpose of making it a useful and permanent asset of the farm. Several varieties of trees suitable for this form of planting are given.

A preliminary working plan for the public forest tract of the Insular Lumber Company, Negros Occidental, Philippine Islands, H. D. EVERETT and H. N. WHITFORD ([*Philippine*] *Bur. Forestry Bul.* 5, pp. 54, figs. 12, map 1).—This work has been prepared to furnish a prescribed plan for the regulation and management of the large tract of public forest granted to the Insular Lumber Company for a period of 20 years, as well as to secure accurate information concerning the timber of this important forest region of the Philippine Islands and to give the native rangers of the bureau training in forest field work. The field work consisted of mapping, botanical surveys, and collection of data for forest management.

Part 1 is a statement of the facts upon which the working plan is based and deals with the general description of the tract, composition and condition of the forest, a description of the principal species of trees, and the utilization of the forest. Historical remarks are given on the development of lumber in this province, together with an account of the present lumbering operations, including remarks on markets, transportation, prices and government charges, prospects, and agricultural possibilities of the land.

Part 2 deals with the future management of the tract, treating of the basis of proposals, method of working the forest, and supplementary recommendations.

In an appendix a list is given of the species of trees mentioned in the text, including the scientific, family, common, and commercial names. A map of the working plan under discussion accompanies the bulletin.

A preliminary working plan for the public forest tract of the Mindoro Lumber and Logging Company, Bongabon River, Mindoro, Philippine Islands, M. L. MERRITT and H. N. WHITFORD ([*Philippine*] *Bur. Forestry Bul.* 6, pp. 55, pls. 14, map 1).—The work upon which this report is based was undertaken for the purpose of forming a preliminary plan of management to be put into operation pending more complete investigation. The tract was inspected, surveyed, and mapped and notes taken on the distribution of the different types of vegetation.

Part 1 is a statement of the facts upon which the working plan is based. A general description of the tract is given, together with the composition and condition of the forest, the characteristics of various types of timber and descriptions of species, injuries to which the forest is liable, the development of the lumbering industry on this tract, and the present lumbering operations, markets, transportation, financial results, and prospects.

Part 2 deals with the future management of the tract. In an appendix is given a list of the few species found on the tract that reach the size of 30 cm. in diameter, together with a list of all the other species mentioned in the text, including the scientific, family, local, and commercial names of each. A map of the working plan accompanies the text.

Financial results of forest management, B. E. FERNOW (*Forestry and Irrig.*, 13 (1907), No. 2, pp. 81-86, fig. 1).—The author traces the progress and presents data as to financial results of Saxon and Prussian forestry administrations. The Saxon forestry area is said to be comparable to New England conditions and the Prussian areas to the conditions existing in our southern pineries and the forests of the Middle Atlantic and Central States. The following are the net returns realized per dollar of expenditure at 3 different periods in Saxony and Prussia, respectively: In 1850, \$1.51 and \$1.25; 1880, \$2.00 and \$1.05; 1904, \$1.77 and \$1.66.

The author believes that much better results can be secured from our own forests providing we take advantage of the hundred years of mistakes and successes in forestry administration in foreign countries.

Annual report of the director of forestry, fiscal year 1906, G. P. AHERN (*[Philippine] Bur. Forestry Rpt. 1906, pp. 27, pls. 16*).—An account of the organization of the bureau and forest districts, field work in the different districts, and laboratory tests. In an appendix a summary is given of the list of licenses issued, amount of timber cut under licenses granted during 1905 and 1906, the utilization of forest products from public lands on which government charges have been collected, the applications for permits to make forest clearings, applications for homestead, purchase, and lease of public lands, imports and exports of timber and other forest products into the Philippine Islands, and of appropriations, expenditures, and revenues for the Bureau of Forestry since its organization.

Tests were made with a large number of Pacific-coast timbers to determine their resistance against attacks of anay (white ant) and of decay. The timber was divided into three series. Series A was untreated and served as a check, series B was treated with mercuric chlorid, and C with creosote. As a result of this experiment it was determined that only untreated woods suffered from the attack of the ant. Fungus diseases had not thus far developed in any case.

In a test of ropes made by home and foreign manufactures, it was shown that rope manufactured in Hongkong and the United States was superior to that manufactured in the islands. This superiority is believed to be due to modern methods of manufacture and the use of high-grade hemp.

The Michigan forestry convention, J. HILDER (*World To-Day*, 12 (1907), No. 2, pp. 209-211, figs. 3).—The chief purpose of the Michigan Forestry Association is said to be to secure the reforestation of cut-over timber lands of no value for general agricultural purposes.

It is hoped that this can be secured by the enactment of laws providing for adequate protection from the fires which yearly sweep over the cut-over lands, for a rational system of taxation under which the trees will be considered as a crop to be taxed when harvested instead of yearly with the land, for the abolition of the homestead law, and the exacting of a minimum price of \$5 an acre for all State lands in order to prevent real estate speculation with these lands. If these laws can be obtained, it is believed that owners will be encouraged to allow the trees to grow until maturity instead of cutting them down when they are large enough to make fence posts.

How to cultivate and care for forest plantations on the semiarid plains (*U. S. Dept. Agr., Forest Serv. Circ. 54, pp. 4*).—This leaflet gives concise instruction for the preservation and maintenance of soil moisture in forest plantations in semiarid regions. The proper distance to space trees for continued cultivation, mulching, tools, and methods of cultivation are dealt with. The planting of crops between trees is said to be unwise, since the trees are deprived of available moisture. The planter is cautioned to afford proper protection against grazing and fire.

Pictorial practical tree and shrub culture, W. P. WRIGHT and W. DALLIMORE (*New York and London: Cassell & Co., Ltd., 1905, pp. 152, figs. 28*).—This book is an illustrated practical manual giving concise directions for the propagation, planting, pruning, and general management of trees and shrubs. The subject-matter is chiefly the work of William Dallimore and is edited by W. P. Wright.

Several chapters are devoted to the use of trees and shrubs for forcing, for the colored foliage, ornamental green leaves, autumn tints, ornamental fruits, ornamental stems, climbing and trailing plants, evergreens, for undergrowth and shade, hedges, and as pendulous plants. Short descriptions are given under each chapter of many of the best trees and shrubs for each of these purposes. There are also lists of the best trees, conifers, and shrubs in alphabetical order.

The importance of selecting seed in practical forestry, G. F. SCOTT-ELLIOT (*Jour. Roy. Hort. Soc. [London], 31 (1906), pp. 147-150*).—A discussion of the experiments carried out by Prof. Adolf Engler in Zurich, in which seeds of picea, pinus, sycamore, and larch were obtained from trees growing at different altitudes and then sowed in experimental gardens at altitudes ranging from 500 or 600 meters to 2,000 meters.

It was demonstrated from these experiments that trees of very high altitudes have developed the habit of forming their annual growth in a much shorter time than trees in lower altitudes and that their seed is not suitable for culture in low altitudes, but is probably the best to plant in the altitudes where the parents were produced. Large seeds, whatever their origin, produce on the whole larger and heavier plants than smaller ones.

How to transplant forest trees (*U. S. Dept. Agr., Forest Serv. Circ. 61, pp. 4, fig. 1*).—This leaflet gives concise instructions for the careful transplanting of forest trees, both in nursery rows and in the field, together with the proper season for transplanting.

How to pack and ship young forest trees (*U. S. Dept. Agr., Forest Serv. Circ. 55, pp. 2, fig. 1*).—Detailed directions are given for the careful handling and packing of young forest trees, with the view of affording proper ventilation and at the same time preventing the roots from drying out.

Forest planting leaflets (*U. S. Dept. Agr., Forest Serv. Circs. 56, pp. 3; 57, pp. 2; 58, pp. 3; 60, pp. 3; 62, pp. 3; 63, pp. 3; 64, pp. 4; 65, pp. 4; 66, pp. 3; 67, pp. 6; 68, pp. 4; 70, pp. 3; 71, pp. 4; 72, pp. 2; 73, pp. 4; 74, pp. 3; 75, pp. 3*).—These are a series of leaflets which treat of the form and size, range, habits, growth, economic uses, methods of propagation, planting, and subsequent care of the following species of forest trees, given in order corresponding to circular numbers above: Bur oak (*Quercus macrocarpa*); Jack pine (*Pinus bairdiana*); red oak (*Quercus rubra*); red pine (*Pinus resinosa*); shagbark hickory (*Hicoria orata*); basswood (*Tilia americana*); black locust (*Robinia pseudacacia*); Norway spruce (*Picea excelsa*); white elm (*Ulmus americana*); white pine (*Pinus strobus*); Scotch pine (*Pinus sylvestris*); European larch (*Larix europaea*); chestnut (*Castanea dentata*); western yellow pine (*Pinus ponderosa*); red cedar (*Juniperus virginiana*); honey locust (*Gleditsia triacanthos*); and hackberry (*Celtis occidentalis*).

Eucalypts (*U. S. Dept. Agr., Forest Serv. Circ. 59, pp. 6*).—This leaflet treats of the blue gum (*Eucalyptus globulus*), red gum (*Eucalyptus rostrata*), and sugar gum (*Eucalyptus corymocalyx*), with respect to their form and size, range, silvical qualities, economic uses, methods of propagation, planting, subsequent care, and their use as wind-breaks. The estimated total cost of a eucalyptus plantation, excluding land rent, at the end of 12 years is \$36.86 per acre, with a probable gross income of \$180.

The Franquette walnut, M. McDONALD (*Pacific Rural Press*, 73 (1907), No. 7, pp. 190).—The author discusses the value of the Franquette walnut as compared with other French varieties for planting in Oregon.

Figures are given showing the increase in yield of a Franquette grove at Santa Rosa, California, from the time the trees were 3 years old in 1901 until they were 8 years old in 1906. During this period the total yield increased from 82 lbs. to 24,314 lbs., and the output practically doubled for each year after 1902.

The chilté tree, COSTANTIN and GALLAUD (*Rev. Gén. Bot.*, 18 (1906), No. 214, pp. 385-391, figs. 2).—An account, including the method of exploitation and an illustrated botanical description, is given of the chilté tree of Mexico, for which the authors propose the name of *Jatropha tepiquensis*. The seeds are used as food in Mexico and the gum is said to have taken the place of chicle (E. S. R., 17, p. 257) in the manufacture of American chewing gum.

The culture of *Ficus elastica* (*Bul. Off. Gourtt. Gén. Algérie*, 1907, Sup. 1, pp. 18).—This work treats more particularly of the species of *Ficus* adapted for the production of rubber. The characteristics which differentiate the *Ficus elastica* from *F. magnolioides* are pointed out.

The manurial requirements of rubber trees (*Trop. Life*, 3 (1907), No. 1, pp. 3-5, figs. 4).—Popular directions are given for the use of commercial fertilizers in the culture of rubber trees.

What I saw in the Tropics, H. C. PEARSON (*New York: India Rubber Pub. Co.*, 1906, pp. 296, figs. 289).—The author relates his personal experiences and adventures during visits to Ceylon, the Federated Malay States, Mexico, Nicaragua, Costa Rica, Republic of Panama, Colombia, Jamaica, and Hawaii. Considerable information concerning the present status of the rubber industry and the various species and varieties under cultivation in these countries is given.

Resinous secretions and resin ducts, A. TSCHIRCH (*Die Harze und die Harzbehälter. Leipzig: Borntraeger Bros.*, 1906, vols. 1, pp. XXII + 1902; 2, pp. 1093-1268, figs. 104).—Volume 1 is a chemical study of resinous secretions and their products. Volume 2 consists of a botanical study of the ducts which contain these resinous secretions. Under resinous secretions the author includes the saps of coniferous, euphorbias, and all rubber-producing trees. The treatise is based on extensive researches of the author and several collaborators, together with information secured from many scientific works.

Effect of moisture upon the strength and stiffness of wood, H. D. TIEMANN (*U. S. Dept. Agr., Forest Serv. Bul.* 70, pp. 144, pls. 4, figs. 25).—This bulletin is a report of a series of tests conducted by the Forest Service in conjunction with the Yale Forest School under the direct supervision of the author. All of the important features of the work are discussed in detail and the results are set forth in numerous tables, figures, plotted curves, and plates.

Besides the main tests, which include the important phases of compression parallel to grain, bending, shearing, and compression at right angles to grain, special tests were made to determine other closely related problems such as the fiber-saturation point, the effect of temperature upon this point, the effect of steaming and boiling, of time of soaking, and of casehardening, and the determination of volatile oils. In all, the report includes over 1,600 mechanical tests and nearly three times as many moisture determinations were made.

Three species of wood were studied and compared. Longleaf pine (*Pinus palustris*) and red spruce (*Picea rubens*) were used as representative coniferous woods, and the chestnut (*Castanea dentata*) as representative of the ring-porous woods. The test specimens were made of the size considered the most satisfactory for experimental purposes, viz, of 2 by 2 in. stuff of different lengths. The results apply especially to the smaller forms of hard and soft

wood material which can be thoroughly and uniformly dried, such as carriage stock, cross-arms for telegraph poles, etc. The author states that the designs of structures should be based on the unit strengths which have been derived from actual tests of large sticks in the condition in which they are to be used.

Drying was found to produce a remarkable increase in the strength, stiffness, and elastic limit of the wood. The effect of dryness upon the shearing strength parallel to the grain is a variable quantity which can not be relied on. Soaking in cold water does not diminish the strength of the wood beyond the point at which the wood fiber becomes saturated. This point the author calls the fiber-saturation point, which is described in substance as follows: Upon immersing a piece of dry wood in water the water is gradually drawn into the pores and also absorbed by the walls of the wood substance. As the latter absorbs more and more water the strength continues to decrease until the point is reached where the walls are saturated and will hold no more. This is the fiber-saturation point and although more water may be taken up by the pores the strength of the wood does not diminish beyond this point, which may also be termed the point at which swelling ceases. Heating the water, however, gradually reduces the strength, since the wood fibers become more fully saturated. Wood that has been dried and remoistened is weaker than wood of an equal degree of moisture which has not been dried. This weakened effect is most marked in the case of steaming at high pressure and is less obvious where the wood is dried slowly at a low heat.

In the introduction to the bulletin W. K. Hatt states, in substance, that as a result of these investigations there have been fully determined the factors by the use of which the results of tests at different degrees of moisture may be reduced to an equal basis in the case of certain species and certain kinds of tests, thereby establishing a percentage of moisture at which the cell walls are saturated in the case of these species, and determining the true nature of the law representing the effect of any further reduction of moisture on the strength of timber. The subsidiary studies in connection with the work, such as casehardening, prolonged soaking, and soaking followed by drying, are believed to have direct application to the technology of various products and to be of great value to students and engineers.

Two appendixes follow the main subject-matter. Appendix A treats of the formulas used in the calculations and describes special studies and subordinate investigations in connection with the work. Appendix B is a discussion of the microscopic study of the fractures produced in the woods by the various tests.

Mechanical tests, properties, and uses of thirty Philippine woods; Philippine sawmills, lumber market, and prices, R. GARDNER ([*Philippine*] *Bur. Forestry Bul. 4*, pp. 69).—This bulletin was prepared to meet inquiries concerning the Philippine woods and milling operations in the Philippines. Tabulated data are given showing the results of tests in cross bending, compression, shear tests, and moisture determinations. These results are also illustrated by several linear curves. The different species tested are discussed as to their structural qualities, appearance, uses, provinces leading in production, sizes, and common and botanical names.

Part 2 gives an account of the present condition of the sawmill industry in the Philippines, together with a discussion of the lumber market and prices.

Wood production and commerce in Europe, Africa, and North America, J. MARCHET (*Holzproduktion und Holzhandel von Europa, Afrika, und Nord-Amerika. Vienna: W. Frick, 1905, pp. 459*).—Statistical data are given showing the timber production of different important timber-producing countries of the world for a number of years up to 1904, and in many instances of the timber imports and exports of the different countries.

Rules and specifications for the grading of lumber, E. R. HOBSON (*U. S. Dept. Agr., Forest Serv. Bul. 71, pp. 127*).—This bulletin contains an enumeration of the rules and specifications for the grading of lumber as adopted by the various lumber manufacturing associations of the United States. A historical account is given of the development of grading in this country, including descriptions of the 4 grades of lumber into which white pine was originally classified. The States having inspection laws are also noted.

Fence-post trees (*U. S. Dept. Agr., Forest Serv. Circ. 69, pp. 4*).—This is a forest planting leaflet giving brief instructions for the planting, cultivation, and care of fence-post plantations, with a list of the best species for this work, as follows: Chestnut, European larch, catalpa, black locust, Osage orange, and Russian mulberry. The economic planting range and suitable soils for each of these species are given.

Examinations of larch plantations in Illinois, Iowa, and eastern Dakota, and hardy catalpa plantations in Illinois, indicate that the returns from fence-post plantations are approximately as great as from field crops. In order to emphasize the importance of selecting well-prepared, fertile soil, the financial returns from 2 hardy catalpa plantations are given. Plantation No. 1 was on a well-prepared, virgin prairie soil; No. 2, on adjacent worn-out farm land. At the end of 14 years No. 1 yielded a net profit of \$170.50 per acre in the value of fence posts cut, whereas plantation No. 2 at the end of 15 years yielded a net profit of only \$3.54 per acre. Both of these plantations received cultivation and pruning at the proper time.

Prolonging the life of mine props (*Forestry and Irrig., 13 (1907), No. 1, pp. 43, 44, figs. 2*).—In experiments which have been recently conducted by the Philadelphia and Reading Coal and Iron Company at its collieries near Pottsville, Pa., under direction of the Forest Service, it has been demonstrated that the preservation of mine props can be put upon a firm commercial basis. The principal preservatives used are creosote and carbolinum, which have been found to be successful both when applied with a brush and in the open-tank treatment. It is believed that the cost may be reduced still further when more is known as to the length of time necessary for immersion. The experiments have been mainly on loblolly pine, the wood most used for mine props.

Wood used for tight cooperage stock in 1905, H. M. HALE (*U. S. Dept. Agr., Forest Serv. Circ. 53, pp. 8*).—This circular is a compilation of statistics on the annual production of tight cooperage stock in the United States and is based on statements of 220 manufacturers. The statistics are compiled in 9 tables, with the important features explained. They show the quantity and value in 1905 of tight cooperage stock, sawed staves, bucked and split staves, hewed staves, sawed heading, etc., used in the manufacture of barrels for oil, distilled spirits, wine, ale, beer, pork, etc. In some instances the production of the different kinds of stock is given by States.

DISEASES OF PLANTS.

Some bacterial diseases of plants, G. DELACROIX (*Ann. Inst. Nat. Agron., 2, ser., 5 (1906), No. 2, pp. 353-368, figs. 4*).—Descriptions are given of the canker of poplars due to *Micrococcus populi*, a bacterial disease of potatoes caused by *Bacillus phytophthorus*, and a bacterial disease of onions attributed to *Bacillus cepivorus*. These diseases have been previously noted (*E. S. R.*, 18, p. 551).

The principal fungus diseases of the year, T. W. KIRK (*New Zeal. Dept. Agr. Ann. Rpt., 14 (1906), pp. 341-365, pls. 13*).—Descriptive notes are given on a number of fungus diseases which have been observed during the year, together

with suggestions for their control. The different diseases are grouped according to the host plants under the following heads: Field crops, grasses, garden plants, vegetables, and fruit trees.

Report of assistant in botany and horticulture, H. S. FAWCETT (*Florida Sta. Rpt. 1906, pp. XXI-XXVII*).—Notes are given on a number of diseases of plants that have been under observation during the past year, and a brief account of a study of the fungus parasites of the white fly, which is proving very destructive in orange groves. Among the more important plant diseases noted are anthracnose and wilt of beans, leaf blight of cantaloupes, rust of celery, scab and wither tip of citrus fruits, cucumber mildew, mango bloom blight, peach crown gall, and tomato leaf blight, leaf mold, wilt, and bacterial blight. For the prevention of most of these diseases thorough spraying with Bordeaux mixture has proved successful.

Annual report of investigations on plant diseases, M. HOLLRUNG ET AL. (*Jahresber. Pflanzenkrankh., 8 (1905), pp. VIII+340*).—This report, published in 1907, gives a review of the literature relating to plant diseases and insect injuries issued during 1905, about 2,200 articles being noted by abstract or otherwise. The arrangement of the topics is essentially the same as that previously given (*E. S. R., 12, p. 658*).

Root diseases of sugar beets, L. PETERS (*Umschau, 11 (1907), No. 5, pp. 85-87, figs. 4*).—The author describes diseases of sugar-beet seedlings due to *Pythium debaryanum*, *Phoma beta*, and *Aphanomyces lavis*. The methods of attack and the effect upon the host plants are described, after which notes are given on the prevention of these diseases, the means suggested including treatment of the seed with fungicides, soil treatments, etc.

The occurrence of alumina and iron oxid in diseased beets, H. PELLET (*Sucr. Indig. et Colon., 69 (1907), No. 5, pp. 118-120*).—In his investigations regarding the bacteriosis of sugar beets (*E. S. R., 12, p. 458*) Stift has shown that as a result of disease the ash content as well as the proportion of iron oxid and alumina are increased.

The author has reviewed the experiments of Stift and carried on investigations with beets attacked by the heart rot (*Phoma beta*). He has confirmed the previous investigations in that his analyses of the ash of the diseased portions of the roots showed a decided increase in the percentage of ash and a higher amount of iron oxid and alumina. These amounts were found to fluctuate widely in different specimens, and the author believes that the increase is not directly due to the disease, but that the roots are rendered much more spongy by reason of the fungus attack. Consequently the fine particles of the soil adhere to them and are not removed in the ordinary process and scrubbing preliminary to analysis.

A fungus disease of greenhouse lettuce, J. B. DANDENO (*Rpt. Mich. Acad. Sci., 8 (1906), pp. 45-47, figs. 2*).—A brief account is given of a disease of greenhouse lettuce, which is reported as being caused by *Marsonia perforans*. This fungus causes characteristic perforations in the leaves and is frequently very troublesome in lettuce houses. A study by the author has led him to the conclusion that the fungus has been wrongly referred, and he proposes for it the name *Didymaria perforans*, a technical description of which is given.

Some notes on the destruction of plum trees, E. RABATÉ (*Semaine Agr. [Paris], 26 (1907), No. 1339, pp. 429, 430*).—According to the author, there has been known in France for many years a peculiar disease of plum trees which is apparently becoming more frequent. The affected trees are covered with gum, the flowers are aborted, and the tips of the young branches are dead. Later the withered appearance of the branches descends to the trunk.

The disease may occur in isolated trees, from which it spreads either along the rows or radially from the center of infection.

An examination of the dead trees shows that there are two parasites, which are usually associated, although sometimes occurring separately. The first is a mushroom, probably *Armillaria mellea*, which develops on the roots and forms a white felt between the bark and the wood of the tree. It also produces rhizomorphs, by which new plum trees, grapevines, and other fruit or forest trees are attacked.

The insect associated with this disease is one of the fruit tree bark borers (*Scolytus rugulosus*). It is most frequently found on trees where there is a decided diminution in the flow of sap, such as follows an attack of the fungus on the roots.

In order to combat this disease the author recommends the burning of all infested trees, the digging of trenches about 30 in. deep around the trees, and disinfecting the soil with carbon bisulphid. Care should be exercised not to replant plum or other susceptible trees in the infected areas. In combating the bark borer, in addition to the suggestions given, the author recommends vigorous pruning, burning the infested branches and bark, and spraying with various insecticides. It will be found that anything that increases the vigor of the trees, such as the removal of mosses, lichens, and fungi, thinning the fruit, etc., will aid in combating this disease.

An outbreak of the European currant rust, F. C. STEWART (*New York State Sta. Tech. Bul. 2, pp. 61-74, pls. 3*).—During September, 1906, the author observed an unusual appearance of the foliage of currant bushes at the station, and an examination showed that they were infested by the European currant rust (*Cronartium ribicola*).

In the plantation there were about 175 plants, including 54 varieties of different species of *Ribes*, 48 of which were more or less infested with the rust. In spite of a very severe attack on the black currants, the plants were in full foliage, and the red and white varieties seemed only slightly affected. In another portion of the station grounds a number of currants of different species were growing, but only two plants were found to be attacked.

Cronartium ribicola appears during the summer and autumn as a conspicuous orange-colored powder on the under surface of the leaves of various species of currants and gooseberries. The acedial form occurs on the trunks and branches of species of pine, particularly the white pine (*Pinus strobus*), where it produces a disease known as blister rust.

The fungus occurs throughout a number of European countries, but has never been reported from Australia or South America, and only once previous to this time from North America. From the information at hand it appears that as a currant disease, *Cronartium ribicola* is regarded as of little importance in those regions where it is abundant, but as a disease of white pine it causes much damage.

The author has undertaken to trace the origin of the outbreak at Geneva, but with little success. It appears that some of the varieties of currants were imported from Europe a few years ago, and that some pines which are near by are also of European origin, so that the fungus possibly was introduced with either the currants or the pines.

In order to stamp out the rust, if possible, every plant of the different species of *Ribes* on the station grounds has been destroyed. The white pines standing near the currant plantation will be kept under observation to see if the disease appears upon them, in which case they too will be destroyed. It is possible that the rust might be controlled on currants and gooseberries by spraying with

Bordeaux mixture, but one application of that fungicide made as soon as the fruit has set apparently had no effect. A bibliography of the fungus is given.

The appressoria of anthracnoses, H. HASSELBRING (*Bot. Gaz.*, 42 (1906), No. 2, pp. 135-142, figs. 7).—A number of observers have reported the presence of peculiar sporelike organs which are produced by the germ tubes of spores of various anthracnoses. By some these are regarded as secondary spores, but it appears that Frank was the first to recognize their true nature, and he gave to the organs of this class the name appressoria, or adhesion organs.

In order to clear up some of the uncertainty regarding these organs the author carried on experiments and observations on the appressoria of the apple bitter rot (*Glaucosporium fructigenum*). His experiments show that the formation of appressoria is induced by a contact stimulus, and in the presence of abundant nutrient material the germ tubes lose their power to react to contact stimuli, and the formation of appressoria is inhibited.

The appressoria were found to germinate readily on a slide when covered with nutrient solution, and the process of penetration was studied by sowing spores on berries of *Berberis thunbergii*. From the pore on the lower flattened side of the adhesion disc a slender tube was observed to protrude, which dissolved a narrow channel in the wax covering of the cuticle. Although at first very slender, the hypha soon became larger and dissolved large cavities in the wax. Finally the cell wall was perforated and the mycelium branched freely within the cells. The penetration of the germ tube through the cuticle of the apple has been frequently observed, but contrary to former supposition no previous injury or puncture of the fruit is necessary.

The behavior of the appressoria of the bitter rot fungus under natural conditions is biologically interesting. The spores of this fungus are embedded in a gelatinous substance, which causes them to stick together in waxy masses when dry. By reason of this condition the spores can not be distributed by the wind, but are almost entirely dependent on rain for dissemination. This has been shown in the conelike distribution areas observed on apple trees due to the washing of the spores from the limb cankers to the apples below.

Since rain is the chief factor in distributing the bitter rot spores, the effect of wetting and drying on the vitality of the spores and the appressoria was studied. It was found that the appressoria are much more resistant to the injurious effect of drying than the spores.

In conclusion the author states that the sporelike organs formed by germ tubes of the anthracnoses are adhesion organs, by means of which the fungus is attached to the surface of its host during the early stages of infection. They are not suited for dissemination and are therefore not to be regarded as spores. The adhesion discs are formed as a result of stimuli from mechanical contact acting on the germ tubes, and under natural conditions the appressoria are formed as soon as the germ tube emerges from the spore.

A disease of the Carolina poplar, G. DELACROIX (*Bul. Trimest. Soc. Mycol. France*, 22 (1906), No. 4, pp. 239-252, pl. 1).—A description is given of a disease of poplars due to *Dothichiza populea*, a previous account of which has been noted (E. S. R., 18, p. 551).

"Cluster-cup" disease of conifers, G. MASSEE (*Roy. Bot. Gard. Kew, Bul. Misc. Inform.*, 1907, No. 1, pp. 1-3, pl. 1).—A description is given of the cluster-cup on certain species of conifers, the fungus being *Calyptospora gæppertiana*. In the alternation of generations, the fungus occurs also on *Vaccinium*, but it has been found that where conifers are not present the fungus can reproduce itself entirely on its *Vaccinium* host.

The cluster-cup stage is reported as occurring on various species of fir, in all 10 species having been observed as host plants, while the resting spore condition

occurs chiefly on *Vaccinium vitis-idaea*, but it has been reported upon other species.

The fungus seems to be rather destructive to young conifers, both in the seed bed and in plantations, and the author recommends care in selecting sites for the seed bed or nursery and the destruction of diseased plants as far as possible.

A sclerotium disease of China asters, F. GUÉGUEN (*Bul. Trimest. Soc. Mycol. France*, 22 (1906), No. 4, pp. 254-265, pl. 1, figs. 5).—A description of a sclerotium disease of China asters in which the fungus attacks the plant at the collar, causing it to be easily decorticated and sooner or later resulting in its destruction. The fungus, which was studied in various media, is designated as *Acrostalagmus vilmorinii* n. sp., a technical description of which is given.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Wolves in relation to stock, game, and the national forest reserves, V. BAILEY (*U. S. Dept. Agr., Forest Serv. Bul.* 72, pp. 31, pls. 3, figs. 5).—The purpose of this bulletin is to furnish information to the hunter, trapper, forest ranger, and ranchman regarding trapping, poisoning, and hunting wolves.

The wolves of the United States are commonly divided into 2 groups, including coyotes and gray, or timber, wolves. The gray wolf of the plains is the more destructive to stock. This animal breeds and builds its dens below the edge of forest reserves or in the open foothill country.

Statements are given regarding the present abundance of wolves in the various States where they occur. Wolves cause the greatest destruction to calves and yearlings, but also attack and kill horses, sheep, goats, hogs, and various game animals. The losses due to the attack of wolves upon calves sometimes amount to 10 per cent.

The protective measures which have been adopted include the use of wolf-proof fences, granting bounties, direct destruction by hunting, poisoning, trapping, and killing of the young in dens. The bounty system has not proved very satisfactory and hunting is too expensive of time and labor. Locating the dens and destroying the young is a very effective way of destroying wolves. The size of the litter ranges from 5 to 13. The breeding season appears to be in January and February. In poisoning wolves the best results are obtained from the use of strychnin, of which from 2 to 4 grains are required to kill a 100-pound wolf. The strychnin should be inclosed in a gelatin capsule and inserted in a piece of beef suet. Directions are also given for the use of traps and the preservation of wolf skins, which are worth from \$4 to \$6 for rugs.

Eleventh annual report of the State entomologist of Minnesota, 1906, F. L. WASHBURN (*Ann. Rpt. State Ent. Minn.*, 11 (1906), pp. VIII + 88, pls. 7 figs. 59).—During the year under report especial attention was given to a study of the cabbage maggot, which caused great injury to cabbage, cauliflower, turnip, and radish plants.

The life history of the insect was studied and experiments were carried out to develop successful methods in controlling it. It seems somewhat impracticable to apply remedies after a field becomes infested. Better results are obtained by preventive methods, particularly cultural ones. Some benefit was obtained from immersing the roots of the plants at the time of setting in hellebore and water, and also from the use of glue and sawdust or bran. The natural enemies of this pest furnish some assistance. Further experiments will be made in developing remedies.

A list is given of insects reported as injurious during the year and also a brief statement of the laws prevailing in different States concerning nursery

inspection. The author also discusses orchard spraying and presents a short entomological calendar. Notes are given on the life history and means of combating a number of injurious insects, including cottony maple scale, soft plum scale, army worm, cutworms, stalk borer, household insects, and white grubs.

Some insects of orchard and other fruits, C. F. ADAMS (*Arkansas Sta. Bul.* 92, pp. 17, figs. 21).—Brief biological and economic notes are given on codling moth, San José scale, apple-twig borer, flat-headed apple borer, buffalo tree hopper, twig girdler, woolly aphid, pear-tree slug, plum gouger, plum curculio, peach borer, peach twig borer, blackberry crown borer, strawberry weevil, etc.

Report of the division of entomology, R. C. L. PERKINS (*Hawaiian Sugar Planters' Sta. Rpt.* 1906, pp. 43-50).—A brief statement is made regarding the work of the traveling entomologists, the distribution of beneficial insects in Hawaii, the inspection of plantations, and miscellaneous entomological work.

Problems in economic entomology in the Philippines, C. S. BANKS (*Philippine Jour. Sci.*, 1 (1906), No. 10, pp. 1067-1074).—Attention is called to some of the economic problems which have arisen in the study of insects in the Philippines. It is believed that special attention must be given to locusts, rice insects, white ants, insects affecting domestic animals, pests of sugar cane, sorghum, tobacco, and forests, and to the study of silkworms and bees.

Entomological notes, J. M. HAYMAN (*Rpt. Cawnpore [India] Agr. Sta.*, 1906, pp. 32, 33).—A pod borer is reported as causing considerable damage every year to chick-peas. The larvæ appear first on the leaves and might be controlled by arsenical sprays applied at that time. Brief notes are also given on a species of *Cecidomyia* found on wheat.

Biological division, C. M. G. JOHNSTON (*Orange River Colony Dept. Agr.*, *Ann. Rpt.*, 2 (1905-6), pp. 243-259, figs. 10).—Attention has been given to the destruction of locusts by spraying and the use of poisoned baits as well as by other methods. Mention is made of the insect parasites of the migratory locust.

Notes are also given on insects injurious to stock and orchard, garden, and field crops, including ticks, bollworm, cutworms, and potato tuber moth. A brief description is included of certain plants which are supposed to be poisonous to stock.

The pests of sugar beets in Bohemia in 1905, H. UZEL (*Ztschr. Zuckerindus. Böhmen*, 31 (1907), No. 4, pp. 217-225, fig. 1).—A list is given of a considerable number of insects which attack sugar beets, and brief mention is made of the injury to sugar beets by nematodes and parasitic fungi.

The boll weevil, C. W. FLYNN, Jr. (*Crop Pest Com. La. Circ.* 11, pp. 19, figs. 2).—In cooperation with the Bureau of Entomology of this Department a number of cultural experiments were carried out in different sections of the cotton belt, during which it appeared that Triumph cotton is the best variety for use in sections infested with the boll weevil. Northern-grown seed, in order to retain its early maturing qualities, must be renewed from its northern sources at least every other year. The results obtained from these experiments confirm previous work along this line, and the author therefore recommends thorough preparation of the soil, early planting, the use of early varieties of cotton, abundant fertilizers, thorough cultivation of the crop, and the destruction of cotton plants in the fall.

Hibernation and development of the cotton-boll weevil, E. D. SANDERSON (*U. S. Dept. Agr., Bur. Ent. Bul.* 63, pt. 1, pp. 1-38, figs. 6).—Since many cotton-boll weevils die during hibernation, it was thought wise to study the effects of various conditions during hibernation upon the mortality of the weevil. It appears that the weevils can not be forced into hibernation until the mean average temperature drops below 60° F. If, therefore, the weevils are deprived

of food during the fall, the percentage of mortality among them may be greatly increased.

The cotton worm is considered of some benefit in this regard, since its chief attack is made upon the cotton plant late in the season, thus destroying the leaves and other edible parts upon which the weevils might otherwise feed. The same result may be brought about by cattle grazing.

The mortality of cotton-boll weevils during hibernation is so great in some instances that not more than 2½ to 15 per cent survive. The maximum rate of mortality in weevils occurs in December or January and is increased by large rainfalls.

The emergence of the maximum number of weevils takes place in Texas from May 20 to June 1. Notes are given on various other points in the biology of the cotton-boll weevil, including summer broods, rate of increase, injury to cotton squares, etc.

Notes on the biology of certain weevils related to the cotton-boll weevil, W. D. PIERCE (*U. S. Dept. Agr., Bur. Ent. Bul. 63, pt. 2, pp. 39-44, pl. 1*).—It is assumed that parasites useful in controlling the cotton-boll weevil may be found by studying its nearest relatives. On this account biological and economic notes are given on *Anthonomus disjunctus*, *A. fulvus*, *A. squamosus*, *Lixus musculus*, *Orthoris crotchii*, etc.

An ant enemy of the cotton-boll weevil, W. E. HINDS (*U. S. Dept. Agr., Bur. Ent. Bul. 63, pt. 3, pp. 45-48, fig. 1*).—Among the native species of ants which prey upon the cotton-boll weevil, *Solenopsis geminata xyloni* is considered to be the most important. This ant is described and notes are given upon its predaceous habits. It eats holes into infested squares and destroys the cotton-boll weevil in such squares in whatever stage they may be found. Among 137 squares entered by ants not a single weevil escaped destruction. The ants nest in the cotton field and appear to be widely distributed through the cotton belt including Texas and western Louisiana.

A predatory bug reported as an enemy of the cotton-boll weevil, A. C. MORGAN (*U. S. Dept. Agr., Bur. Ent. Bul. 63, pt. 4, pp. 49-54, figs. 2*).—A report was received that *Apiomerus spissipes* was attacking the cotton-boll weevil. A study was made of this bug, giving attention to its life history, food habits, distribution, and natural enemies.

The results were unfavorable to the supposition that the bug is of value in controlling the cotton-boll weevil. It is comparatively rare in cotton fields especially during the time when the weevils are most numerous and the young bugs show a high rate of mortality.

The brown-tail moth and the gypsy moth in New Hampshire in 1906, E. D. SANDERSON and L. O. HOWARD (*New Hampshire Sta. Bul. 128, pp. 211-230, figs. 8*).—A statement is made of the spread and present distribution of the brown-tail moth and of the work which has been done by various towns in combating it. During the season of 1905-6 about \$6,000 was spent by the towns in New Hampshire in this work. The best results are obtained from the destruction of winter webs, but spraying is effective if done in early May.

The State has not taken up the control of the gypsy moth and work thus far done against this insect has been under the supervision of this Department. The present status of the gypsy moth in New Hampshire is outlined. It is estimated that the preliminary work of inspection will cost about \$150 per town; putting on burlaps and attending them for 2 months, \$1,000 per town; and the total cost of thorough work of control about \$2,000 per town.

The oyster-shell scale, T. B. SYMONS (*Maryland Sta. Bul. 111, pp. 57-70, figs. 8*).—During the past 2 years the oyster-shell scale has attacked and destroyed a large number of mature maple trees. The insect is found chiefly

on the young branches and does not cause the death of the trees except after an infestation of considerable duration. Brief notes are given on the life history and food plants of this pest. The author tried, apparently for the first time, lime-sulphur-salt as a remedy for oyster-shell scale on maples. The trees were sprayed in November and April, and it was found that the insect could be controlled with satisfactory results and without injury to the trees.

If only one application is possible the fall appears to be the better time. A thorough application in the spring, however, may sometimes be even more effective. Lime-sulphur-salt should be used only during the dormant season. Kerosene emulsion gives excellent results if applied in May when the young scales are just beginning to crawl about.

Combating the oyster-shell bark-louse and other entomological problems, DUKE OF BEDFORD and S. U. PICKERING (*Woburn Expt. Fruit Farm Rpt., 6 (1906), pp. V + 235*).—On account of the extensive injury caused to fruit growers by the oyster-shell bark-louse, the authors organized an elaborate and thorough campaign for determining the most effective and practical remedies against this pest.

Winter applications of insecticides were made for the purpose of destroying eggs and removing moss and lichens from the bark. The alkali wash generally recommended for winter use is a 2 per cent solution of caustic soda and carbonate of potash. The experiments carried on by the authors, however, indicate that carbonate of potash has very little effect and that the value of the mixture is lessened by substituting any of it for a 2 per cent solution of caustic soda. The best results were obtained by a mixture containing 2 per cent caustic soda and 2 or 3 per cent of soap. The soda-soap wash destroys from 70 to 90 per cent of the eggs.

Less satisfactory results followed the use of kerosene emulsions, since when enough kerosene was added to be effective the trees were injured, and a sufficient quantity of soap appeared to be too expensive. Further experiments along this line, however, showed that a weak kerosene emulsion containing 2 per cent of caustic soda would destroy all of the eggs. This mixture contains 6 per cent of kerosene and 0.5 per cent of soap, the preparation being made of 1½ lbs. of soft soap, 2 gal. of kerosene, and 6 lbs. of caustic soda per 30 gal. of water.

The authors do not recommend the use of undiluted kerosene for spraying purposes. Fumigation with hydrocyanic-acid gas in ordinary proportions also had no effect on the eggs of the scale. For summer treatment the use of a weak kerosene emulsion containing 1.25 per cent of kerosene and 2.5 per cent of soap is recommended.

A summary is presented of the work which has thus far been done in this country and elsewhere on the San José scale. In destroying moss good results followed the use of a 2 per cent solution of caustic soda. The authors also obtained satisfactory results from the use of lead arsenate as an insecticide for leaf-eating caterpillars.

Treating San José scale, T. B. SYMONS and A. B. GAHAN (*Maryland Sta. Bul. 112, pp. 71-88, figs. 7*).—The aggressive orchardists of Maryland are able to control the San José scale, but in a number of localities this pest affords serious difficulties. Wherever osage orange hedges become infested the difficulty of eradicating the San José scale is increased.

A number of experiments were tried with different insecticides in combating the pest. Lime and sulphur mixtures were used containing from 20 to 30 lbs. of lime and from 15 to 25 lbs. of sulphur per 50 gal. of water. The lime-sulphur-salt mixture, tested by the authors, was made according to the formula 20-15-10-50.

Lime-sulphur-caustic soda preparations were also employed, as well as a mixture containing 15 lbs. sulphur and 10 lbs. of caustic soda per 50 gal. of water.

In most cases the weaker lime-sulphur preparations were about as effective as the stronger, but in a few instances an increased effectiveness was noticed where 35 lbs. of lime and 30 lbs. of sulphur were used per 50 gal. of water. Perfectly satisfactory results were obtained from the use of lime-sulphur-salt, and lime-sulphur-caustic soda also proved fairly effective. The sulphur-caustic soda mixture was not so satisfactory. Kerosene limoid did not prove to be a good substitute for lime-sulphur. Certain proprietary remedies were tested and notes were given on the preparation of the various insecticides which were used.

The black currant gall mite, W. E. COLLINGE (*Jour. Bd. Agr. [London]*, 13 (1907), No. 10, pp. 585-596).—The life history of this pest is described and a brief account is given of previous work which has been done in attempts to combat it. In the author's opinion no varieties of the currant are absolutely immune to its attacks.

Fumigation with hydrocyanic-acid gas is not very satisfactory and is too troublesome in large plantations. The author tested a considerable number of insecticides and comes to the conclusion that the application of lime and sulphur will keep the mite in check and, if the spray is applied repeatedly, will perhaps eradicate the pest.

The grape berry worm, H. A. GOSSARD and J. S. HOUSER (*Ohio Sta. Circ.* 63, pp. 16, figs. 12).—During the past 2 or 3 years the grape berry worm has been an unusually serious pest in Ohio, and along the shore of Lake Erie has caused the loss of about one-third of the grape crop. The eggs are minute translucent bodies found on the skins of the grapes in the summer, and the point of entrance of the larvæ into the grape is surrounded by a patch of reddened skin.

In order that the most effective remedies should be directed against the first brood, operations should begin during the fall, consisting of clean cultivation, the destruction of all trash about the vineyard, and thorough plowing. The authors are somewhat in doubt whether fall or spring plowing is best, but it is found that as good results can be obtained by plowing as by burning. The most important measure of all is believed to be spraying with arsenate of lead or Paris green. The arsenate of lead should be used at the rate of 3 lbs. to 50 gal. of Bordeaux mixture. It is recommended that the first application be made in early June, the second as soon as the grapes are through blooming, and the third early in July. The cost of spraying an acre of grapes ranges from \$3.75 to \$5.

Combating insects and other enemies of agriculture, F. LAFONT (*La Lutte contre les Insectes et Autres Ennemis de l'Agriculture*. Paris: Masson & Co. [1906], pp. 174).—The usual remedies adopted in controlling insects are outlined with formulas for a large number of insecticides and methods of applying them. The subject-matter concerning specific injurious insects is arranged according to the plants upon which the insects depredate and includes insects which have a wide range of food plants, and enemies of cereals, forage plants, garden vegetables, small fruits, and orchards.

The method for destroying larvæ in tree plantations, EBERHARDT (*Compt. Rend. Acad. Sci. [Paris]*, 144 (1907), No. 2, pp. 95-98).—Difficulties are everywhere experienced in combating the larvæ of beetles and other insects which bore in the twigs and trunks of trees. Such larvæ cause enormous losses in Indo-China, especially in plantations of tea, mulberries, and oranges.

In fighting these pests the author recommends that the larvæ be removed by means of a knife and that the wounds be subsequently treated with an anti-

septic wash. For wounds in growing twigs the author recommends a solution containing 4 parts glycerin and 11 parts formalin in 85 parts of water. For wounds in trunks of trees a formula is suggested calling for 6 parts of glycerin and 18 parts of formalin in 76 parts of water.

Third report on dust and liquid spraying, C. P. CLOSE (*Delaware Sta. Bul.* 76, pp. 19).—The work reported in this bulletin largely confirms previous results obtained by the station (E. S. R., 17, p. 994). A comparison was made between dusting with Paris green and full strength or half strength Bordeaux with Paris green and also between Paris green and arsenate of lead with Bordeaux mixture. The kerosene-lime-Bordeaux poison mixture was also tested. Applications of these insecticides were made on apple orchards, including several varieties. It was found that the total cost of spraying with dust was 2 cts. per tree, as compared with 4.75 cts. with the liquid application.

Details of results are presented in a tabular form. The comparison of full strength and half strength Bordeaux mixture showed that the half strength kept the fruit and foliage apparently as healthy as was the case when full strength Bordeaux mixture was used. The apples showed no russeting, but the amount of dropped fruit was somewhat less when the full strength mixture was applied. The liquid spray controlled bitter rot better than dust spray, but apple scab was entirely controlled by either method.

A preliminary account of the life history of the common house fly, C. G. HEWITT (*Mem. and Proc. Manchester Lit. and Phil. Soc.*, 51 (1906-7), pt. 1, No. 1, pp. 1-4).—According to the author's observations each female house fly deposits about 120 eggs in fresh horse manure. In hot weather it was found that the whole life cycle might be passed through in 15 days.

Apiculture, T. W. KIRK (*New Zeal. Dept. Agr. Ann. Rpt.*, 14 (1906), pp. 427-434, pls. 6, figs. 3).—The subject of poisonous honey was investigated. In samples of honey said to have been poisonous to native Maoris, pollen grains were found apparently belonging to *Ranunculus rivularis* or some related species and other honey-producing plants, particularly *Knightia excelsa*. The evidence obtained in this study was not conclusive, but indicates that the pollen grains of some of the plants may exercise a poisonous effect.

Notes are also given on the inspection of apiaries, the organization of a state apiary, foul brood, and the introduction of bees into New Zealand.

Bees, A. LUDWIG (*Usere Bienen*. Berlin: F. Pfennigstorff [1907], pp. VIII + 831, pls. 54, figs. 369).—The present volume constitutes an elaborate handbook covering all the points on which the bee raiser desires information. Special chapters are devoted to the biology and life history of bees, economic importance of apiculture, various methods of managing bees, bee apparatus and appliances, the utilization of honey, the history and present status of the varieties of bees, the diseases of bees, and other related matters.

Breeding bees by selection, F. W. L. SLADEN (*Brit. Bee Jour.*, 35 (1907), No. 1282, pp. 21-23).—In the author's first efforts to improve the honey-producing character of bees, little difficulty was experienced in making selection of the best honey-producing colonies on the queen side, but on the drone side the selection was much more difficult. At first it was almost impossible to identify the offspring of particular queens and drones. Finally differences in color were hit upon as furnishing a means for such selection.

It was soon found that there was little or no correlation between the color character and the honey-producing character. These two characters appeared to be inherited independently. There were dark and light colored bees of high and low honey-producing power. All the light-colored bees except the best honey producers were eliminated from the breeding experiments, and light-colored drones of good parentage were crossed on queens obtained in this way.

The color effects thus produced in breeding could be distinguished as soon as the first few hundred workers were hatched or within a month after the queen was fertilized. A bright-colored race of bees has been produced by this system of selection from crossing the black native bees and the American Golden Italian bee. The name British Golden bee has been given to the new race and a considerable improvement in honey production has been noted.

After the characters have been fixed in some of the offspring obtained from crossbreeding, it has been found that "the workers of the colony that produced the drones' mother show fairly accurately the characters that the drones are likely to transmit."

Sericulture in Indo-China, P. VIEIL (*Bul. Écon. Indo-Chine, n. ser., 9 (1906), No. 57, pp. 939-973, figs. 15*).—A general account is given of the culture of mulberries in Indo-China for feeding to silkworms and of the varieties of the mulberries planted for this purpose. The commonest race of silkworms in Indo-China is one with several generations a year and with golden cocoons. A description is also given of the diseases of silkworms and of various technical operations in connection with this industry.

Silkworms of Madagascar, GRANGEON (*Agr. Prat. Pays Chauds, 6 (1906), Nos. 44, pp. 362-369; 45, pp. 495-502, figs. 14*).—Notes are given on the races of silkworms observed in Madagascar and on the insect, fungus, and bacterial diseases which attack them.

On the polygamous habit of the silkworm, K. TOYAMA (*Bul. Assoc. Seric. Japon, 1907, No. 176, pp. 1-15*).—The belief prevails among many silk raisers in Japan that silkworms should be kept in monogamous condition in order to secure the greatest health of offspring. An experimental study of this, however, showed that there is no appreciable difference in the vigor of offspring whether the male moths are mated with one or six or more females. Further studies along this line are contemplated.

FOODS—HUMAN NUTRITION.

Instructions concerning trade labels under the meat-inspection law and regulations, A. D. MELVIN (*U. S. Dept. Agr., Bur. Anim. Indus., pp. 6*).—In this circular, issued Dec. 10, 1906, the instructions given are intended, so far as possible, to cover the interpretation of the meat-inspection law regarding trade labels and to give the tentative rulings made by the Pure Food Commission under the national pure-food law.

"The essential features of a label must be placed together in any desired order without interspersing any descriptive, qualifying, or advertising matter. The essential features are as follows:

"The true name of the product.

"The true name of the manufacturer, if given.

"The true name of the place of manufacture, if given.

"The name of the manufacturer is not required under the meat-inspection or pure-food laws, but if given it must be the true name.

"Persons, firms, or corporations owning subsidiary companies having legal entity may use the names of such companies, provided application has been made for inspection, and it has been granted; the inspection legend in such case to bear the establishment number of the parent firm or corporation."

Examples are given showing the application, of the feature outlined, to labels for ham, sausage, lard, lard compounds, substitutes, etc.

Food inspection, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 135, pp. 229-250*).—This bulletin contains the text of the State pure-food law enacted in

1905 and the revised standards of purity of food products which have been adopted for Maine.

Food inspection, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul.* 136, pp. 251-282).—Under the State pure-food law a number of samples of baking powders, spices, and vinegars were examined.

With the exception of 2 samples of old goods, the baking powders were correctly labeled. All the samples of allspice, cassia and cinnamon, ginger, cloves, and Cayenne or red pepper were genuine, though some samples of ginger were weak and may have contained exhausted ginger and some of the samples of cloves carried undue amounts of cloves' stems, and others may have contained exhausted material. Several samples of mustard and black pepper were adulterated. The vinegars on sale were in general more satisfactory than a year ago, "still the analyses show that vinegars were on sale in the State that were not correctly branded."

Food analyses: Report of chemist, J. T. WILLARD (*Bul. Kans. Bd. Health*, 2 (1906), No. 6, pp. 150-161).—A large number of samples of canned goods, pickles, flavoring extracts, condiments, dairy products, flour, and meat were examined and a method described for the detection of bleaching in flour.

Small quantities of flour are shaken with a few cubic centimeters of water and the mixture tested for nitrites. "One-half gram of sulfanilic acid is dissolved by heat in 150 cc. of dilute acetic acid. One-tenth gram of α -naphthylamin is heated with 20 cc. of strong acetic acid and the colorless solution poured off from the residue and mixed with 130 cc. of dilute acetic acid. For use, the 2 solutions are mixed in equal quantities and 2 cc. of the mixed solution added to the liquid to be tested."

Investigations on the properties of wheat proteids, J. S. CHAMBERLAIN (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 11, pp. 1657-1667).—The author's conclusions were in effect as follows: Dry gluten contains about 75 per cent proteids and 25 per cent nonprotein bodies. Of the total proteids present in wheat 60 to 65 per cent are present in the gluten and 35 to 40 per cent are lost in the washings.

The balance between the nonprotein present in the gluten and the loss of protein in washing makes gluten determinations agree roughly with total protein calculated from total nitrogen, but they will usually run below with whole wheat and above with flours.

The amount of total protein present in gluten is about 15 per cent less than the sum of the gliadin and glutenin determined by extraction of the wheat, and the loss of protein in washing out gluten is more than equal to the salt solution soluble protein. Therefore the loss of protein in the determination of gluten is at the expense of gliadin or glutenin, the true gluten protein of wheat.

On account of these losses and errors the author believes that the determination of gluten yields no information which can not be gained either from the determination of total protein or the determination of the alcohol soluble and insoluble proteids.

The constitution of Java cane-sugar molasses, H. C. P. GEERLIGS (*Internat. Sugar Jour.*, 8 (1906), Nos. 85, pp. 26-35; 86, pp. 86-95; 87, pp. 156-164).—Some of the conclusions follow which were drawn from an extended study of Java sugar cane and molasses:

"The constitution of the molasses is chiefly governed by the constitution of the sirup, and this again is dependent on the constitution of the raw cane juice and on the method of clarification.

"The percentage of inorganic elements in the raw juice, together with its glucose content, is one of the chief factors for the limit below which the molas-

ses can not be further desaccharified; in so far that a high quotient between glucose and ash coincides with a low quotient of purity, and vice versa.

"The amount of inorganic constituents, principally potash salts, in the juice is a consequence of the conditions of the soil, the climate, and the labor, and is to a certain extent constant for the cane from any given area.

"Generally, a low quotient of purity of the juice of ripe cane accords with a high content of inorganic bodies, chiefly potash salts. . . .

"Carbonatation removes gums, phosphates, and silica much more thoroughly than defecation."

The value of cocoa as a food and condiment. Experiments with man, R. O. NEUMANN (*Arch. Hyg.*, 58 (1906), No. 1, pp. 1-124, pls. 3, figs. 8; *München. Med. Wechschr.*, 53 (1906), No. 10, pp. 781, 782).—A large number of experiments with cocoa of different sorts were made in which the effect of the quantity eaten, the fat content, the amount of shell present, and other questions were studied. Among the conclusions drawn were the following:

The way in which cocoa is consumed, whether alone or with other foods, has a marked effect on its absorption. The minimum digestibility of protein, 45 per cent, was noted when cocoa was eaten alone. The presence of cocoa diminished the digestibility of nitrogenous constituents of the diet as a whole, the amount being proportional to the quantity of cocoa taken. This lowering of protein digestibility is due to the fact that cocoa increases markedly the amount of feces. This increase is accompanied by a corresponding decrease in the amount of nitrogen in the urine. The lower the fat content of the cocoa the greater the depression of the coefficient of digestibility of protein. A large proportion of shell in cocoa also has an unfavorable effect on the excretion of nitrogen. Cocoa protein may replace a part of the protein of the diet. The digestibility of cocoa fat varies considerably, the separated cocoa butter being 94.7 per cent digestible, as compared with 94.9 per cent in the case of the fat of a normal diet. When fat is taken as a part of the cocoa its coefficient of digestibility is somewhat lower. Cocoas rich in fat improve the digestibility of the fat of the entire diet. When large quantities of cocoa are taken the theobromin present produces transitory disturbances, but the amount present in small quantities of cocoa, such as the 20 or 30 gm. ordinarily taken per day, produces a pleasantly stimulating effect. No diuretic effect was noted.

In general, the experiments showed that cocoa was a satisfactory food material and, in the author's opinion, cocoa with a high fat content is to be preferred to one from which the fat has been very largely removed. He therefore suggests a fat content of 30 per cent as the minimum requirement.

Chemical composition of chestnut flour, and study of two sugars contained therein, R. PALADINO (*Rend. Accad. Sci. Fis. Mat. Napoli*, 3, ser., 12 (1906), pp. 117-123; *abs. in Jour. Chem. Soc. [London]*, 90 (1906), No. 527, pp. 624, 625).—One of the sugars identified gave crystals resembling those of sucrose and gave an osazone melting at 204° C. It had a specific rotation corresponding to that of sucrose. The aqueous extract yielded a reducing dextrorotatory sugar which gave an osazone melting at 204°.

The presence of formalin in foods, G. PERRIER (*Compt. Rend. Acad. Sci. [Paris]*, 143 (1906), No. 17, pp. 600-603).—The possible occurrence of formalin in smoked food products is pointed out and determinations reported of the amount present in a number of products; for instance, 0.03 to 1.20 mg. was found per 100 gm. in ham and 0.04 to 0.6 mg. per 100 gm. in smoked sausage. The necessity of taking into account in pure-food legislation the occurrence of formalin under such circumstances is pointed out.

The volume and specific weight of the human body, J. WENGLER (*Arch. Physiol.* [Pflüger], 115 (1906), No. 11-12, pp. 612-621, fig. 1).—Using specially constructed apparatus the author measured the volume and specific gravity of the human body as it is ordinarily considered and with the exclusion of the included air which is variable in quantity. According to his results the body volume of the person experimented upon, exclusive of the air contained in the body, was 71.76 liters, and the specific gravity of the body substance, air excluded, was 1.05.

On the influence of neutral salts upon the rate of salivary digestion, JANE B. PATTEN and P. G. STILES (*Amer. Jour. Physiol.*, 17 (1906), No. 1, pp. 26-31).—As shown by the experimental data, ptyalin is very active in the presence of many salts in high concentration, the effect being observed even in the case of some saturated solutions, notably those of magnesium sulphate and ammonium chlorid.

"The most striking instances of accelerating effects were obtained with salts of magnesium, calcium, and barium—belonging to a natural chemical group. But with increasing concentration these salts diverge in their behavior, and calcium chlorid at last restrains the enzyme, which never becomes true of magnesium sulphate.

"When we compare the retarding influence of salts of ammonium, potassium, and sodium we find the ammonium compound much less active in checking the digestion than either of the other two. There seems to be no marked difference between the sodium and the potassium salts. Sodium chlorid retards somewhat more than does potassium chlorid, and this order holds for the sulphates, but seems to be reversed for the benzoates."

Other questions were also considered.

Investigations in physical chemistry and their relation to digestion and resorption, E. REISS (*Zentbl. Gesam. Physiol. u. Path. Stoffwechsels. n. ser.*, 1 (1906), Nos. 12, pp. 353-360; 13, pp. 404-415, fig. 1; 14, pp. 438-447).—Recent advances in physical chemistry are summarized and discussed with special reference to the physiology of secretion, resorption, and digestion, and also the pathology of the subject.

The chemistry and biochemistry of creatin and creatinin, O. FÖLIN (*Upsala Läkareför. Förhandl. n. ser.*, 11 (1906), Sup. III, pp. 20).—Having shown by laboratory experiments that creatin can not be readily converted into creatinin, the author carried on experiments to determine whether the commonly accepted view is tenable that creatin is a waste product of protein metabolism, which is eliminated in the urine in the form of its anhydrid creatinin.

The conversion of creatin of the food into creatinin was not observed in the body. Neither creatin taken in the food nor the nitrogen equivalent to it was found in the urine when it was taken in a diet low in protein. It was, however, apparently utilized in the body, as none was found in the feces. When taken with a diet rich in protein creatin itself rather than its decomposition products appeared in the urine.

As a working hypothesis for subsequent experiments, the author suggests the theory that creatin as distinguished from creatinin is a food and not a waste product. Its behavior is clearly unlike that of an ordinary amino-acid, the nitrogen of which would appear as urea.

"It is possible that the nitrogenous substances which serve to maintain the nitrogen equilibrium in the living tissues are special products which do not easily take part in the urea-forming processes. Creatin may be one such product, is therefore retained in the general tissues, and consequently we find the muscles rich in creatin. When the organism is daily supplied with an abundance of protein it may then be preparing as much creatin as is needed

for the maintenance of its normal supply. The creatin given with the food is consequently not absorbed and retained by the muscles to the same extent as when the food contains an insufficient supply of protein."

Experiments on the origin of creatin in the animal body, M. JAFFÉ (*Ztschr. Physiol. Chem.*, 78 (1906), No. 5, pp. 730-768).—Glycoeyamin (guanidiu acetic acid) forms creatin in the body by the addition of a methyl radical. Arginin is probably not an intermediate product. The experiments were made with rabbits.

The excretion of creatin and creatinin by man, K. O. AF KLERCKER (*Beitr. Chem. Physiol. u. Path.*, 8 (1906), No. 1-2, pp. 59-61).—According to the author's experiments the consumption of protein had practically no influence upon creatinin excretion.

In general the author is of the opinion that although most of the creatin and creatinin supplied by the food is excreted through the kidneys, a little is utilized by the body, creatin being the more readily utilized of the two. His experiments furnish no evidence that any exogenous creatin is converted into creatinin.

The elimination of creatinin, O. E. CLOSSON (*Amer. Jour. Physiol.*, 16 (1906), No. 2, pp. 252-267, fig. 1).—The data reported indicate that creatinin is a constituent of the urine from an early period in man, dogs, and cats, and, independent of the ingestion of creatin and creatinin, forms a characteristic endogenous catabolic end product of metabolism.

Experiments on the physiological action and metabolism of anhydro-oxymethylene-diphosphoric acid (phytin acid), L. B. MENDEL and F. P. UNDERHILL (*Amer. Jour. Physiol.*, 17 (1906), No. 1, pp. 75-88).—According to the authors, a solution of anhydro-oxymethylene-diphosphoric acid, the acid radical of phytin, prepared from wheat bran, appears to be quite stable. When present in sufficient concentration it hinders growth of bacteria, but the salts of the acid are not noticeably bactericidal.

As shown by the experiments reported, "comparatively large doses of the phospho-organic acid, used as the sodium salt, can be introduced into animals either per os, subcutaneously, intraperitoneally, or intravenously, without unfavorable effects. The free acid is more toxic.

"No marked or immediate characteristic effects of the sodium salt upon general health or nitrogenous metabolism have been observed. The compound is readily absorbed and speedily transformed within the organism. Its phosphorus reappears in the excreta as inorganic phosphates. No constant relation between the metabolism of nitrogen and of phosphorus was observed. In these details our experience with the dog corresponds with the observations of Jordan, Hart, and Patten after feeding phytin to cattle. [E. S. R., 18, p. 568.] Our results differ in showing that in both the dog and rabbit the excess of phosphorus was almost entirely eliminated through the kidneys rather than in the feces. This may have an important bearing on the possibility of producing laxative effects with phytin.

"In our experimental animals purgative action could not be constantly provoked. Very large doses were frequently effective. No permanent generalizations can be drawn from the observations made on this point."

The effect of different factors upon the digestion of protein, P. SALECKER and A. STUTZER (*Jour. Landw.*, 57 (1906), No. 3, pp. 273-282).—A lowering of the digestibility of protein is noticed in many cases when nitrogenous materials heated for a considerable time at a temperature under that of boiling water are treated with pepsin hydrochloric acid. Apparently the lower digestibility is not due to the action of atmospheric oxygen, but to some molecular change in the proteid molecule. Peat lowers the digestibility of protein, so this material

is not a desirable one to use with molasses in the manufacture of feeding stuffs. When formaldehyde is used as a preservative for substances containing nitrogen the protein is rendered insoluble but, according to the authors, is not indigestible.

The cleavage of protein in the intestine, O. COHNHEIM (*Ztschr. Physiol. Chem.*, 49 (1906), No. 1, pp. 64-71).—Through the combined action of pepsin and erepsin very thorough and probably complete cleavage of protein is induced, according to the author's experiments. The reaction is comparatively rapid, being a question of minutes or hours and not of days.

Concerning proteid synthesis in the animal body, H. LÜTHJE (*Arch. Physiol. [Pflüger]*, 113 (1906), No. 11-12, pp. 547-604).—Since rabbits often live on roots and potatoes, which contain at least 50 per cent of their nitrogen in nonproteid forms, feeding experiments were made to learn the value of the different nitrogenous constituents. When the nonproteid nitrogenous material of potatoes was fed the rabbits died. In other words, this material did not prevent proteid starvation.

The importance of individual amino acids in metabolism, EDITH G. WILCOCK and F. G. HOPKINS (*Jour. Physiol.*, 35 (1906), No. 1-2, pp. 88-102, *dgm.* 1).—Zein, obtained by extracting corn meal with 75 per cent alcohol, the authors conclude from their experiments with mice "has no power whatever of maintaining growth in the young animal; loss of weight begins the moment it forms the sole nitrogenous supply. The addition of the missing tryptophan group to the zein has, it is also clear, no power to convert such loss into equilibrium or gain; a fact possibly due to other deficiencies in the zein molecule, such as the absence of lysin, or the lack of some other amino acid not yet observed. There was no close relationship in our experiments between the loss of weight and the length of survival period."

Can nitrogen equilibrium be produced in the animal body by heteroalbumoses? V. HENRIQUES and C. HANSEN (*Ztschr. Physiol. Chem.*, 48 (1906), No. 5, pp. 383-386).—The experimental data led to the conclusion that heteroalbumoses and also disalbumose serve as protectors of protein.

Experimental researches on the expiration of free nitrogen from the body, A. KROGH (*Skand. Arch. Physiol.*, 18 (1906), No. 5-6, pp. 364-420, *pl.* 1, *figs.* 8).—Using a Regnault closed-circuit respiration apparatus of special construction, which is described, experiments were made with chrysalides, eggs, and mice with a view to determining the possibilities of the excretion of free nitrogen. The experiments ranged in length from a few hours to nearly 3 days.

Experiments similar to the early series reported by Regnault and Reiset^a were also made with small animals confined under bell jars.

According to the author, his investigations as a whole show only "an extremely slight production of gaseous nitrogen, amounting in the case of eggs to 1.5 cc. during the whole period of incubation and in that of mice to 0.01 per cent of the absorbed volume of oxygen. The productions found may be accounted for, as being due to excretion of ammonia or, in the case of eggs, as the setting free of physically dissolved nitrogen. The albumin metabolism does not give rise to any excretion of free gaseous nitrogen from the body."

The sources of error in the work of earlier investigators, who reported a considerable excretion of free nitrogen are pointed out.

The physiological effect of organic bases derived from beef, F. KUTSCHER and A. LOHMANN (*Arch. Physiol. [Pflüger]*, 114 (1906), No. 11-12, pp. 553-568, *pls.* 4, *dgms.* 7).—Using small animals the physiological effects of oblitin, novain, ignotin, and neosin were studied.

So far as the experiments showed, ignotin had no physiological effect.

^a Ann. Chim. et Phys., 3. ser., 26 (1856), p. 310.

Marked effects were noted, however, with oblitin and novain and these bodies were apparently similar in their properties. Neosin also produced physiological effects, but, owing to a lack of material, it was not possible to determine whether or not this body was related to oblitin and novain.

The extractives of muscles. IV, The occurrence of carnosin, carnitin, and methylguanidin in meat, R. KRIMBERG (*Ztschr. Physiol. Chem.*, 38 (1906), No. 5, pp. 412-418).—From the experimental data the author concludes that the carnosin, carnitin, and methylguanidin found in meat extract exist in the living muscular tissue.

Muscle extractives. V, The constitution of carnitin, R. KRIMBERG (*Ztschr. Physiol. Chem.*, 39 (1906), No. 1, pp. 89-95).—A progress report of the study of the chemical constitution of carnitin. From data at present available it appears that carnitin is a derivative of trimethylamin or contains a trimethylamin group.

Intestinal gases of man, J. A. FRIES (*Amer. Jour. Physiol.*, 16 (1906), No. 4, pp. 468-474).—On an average the samples of intestinal gas analyzed contained by volume 10.3 per cent carbon dioxid, 0.7 per cent oxygen, 29.6 per cent methan, and 59.4 per cent free nitrogen. The author believes that the large amount of free nitrogen is not a decomposition product, but rather atmospheric nitrogen swallowed as air with the liquid and solid foods and with the saliva, the oxygen of the air having been absorbed into the blood or having been utilized in some way by the living body.

As to the value of these indifferent gases, carbon dioxid, marsh gas, and oxygen, in man and animals little is definitely known. "We can but conjecture and ascribe to . . . [such a mixture] a rôle of usefulness in the scheme of digestion and assimilation of the food, in that this gas mixture may serve as a regulating agency to regulate the growth of micro-organisms in the digestive tract, checking the growth of some, preventing the growth of others which may find their way into the intestines."

ANIMAL PRODUCTION.

Feeding stuffs, P. DECHAMBRE (*Les Aliments du Bétail. Paris: Asselin & Houzau, 1906, pp. XV+578*).—A handbook of information regarding materials of importance in feeding farm animals. Composition, digestibility, nutritive ratio, intensive feeding, and related questions are discussed, and the cereal grains and different feeding stuffs, including commercial by-products, are considered in detail.

Concerning the rôle of asparagin in nitrogen metabolism in the animal body, C. LEHMANN (*Arch. Physiol. [Pflüger]*, 112 (1906), No. 7-8, pp. 335-351, pl. 1).—Powdered asparagin and asparagin pressed into small tablets which were coated with celluloidin were compared as a part of the ration in experiments with a dog, the celluloidin being used to retard the action of the digestive juices. The conclusion was reached that when such action was hindered amids exercised a decided and favorable effect on nitrogen metabolism.

The author points out that in earlier experiments in which asparagin has been mixed directly with the feed and so taken in a form in which it was immediately soluble unfavorable results have been obtained and that, when asparagin occurs normally in feeding stuffs, it is inclosed in cells or is distributed in a large bulk of feeding stuff so that it is very slowly available to the bacteria which convert it into complicated nitrogenous compounds.

The utilization of beet tops and leaves in the feeding of farm animals, P. DIEFLOTH (*Soc. Aliment. Rationn. Bétail, Compt. Rendu 10. Cong., 1906,*

pp. 45-56).—A summary of data in which the feeding value of beet tops and beet leaves is pointed out.

Ensiling beets and beet pulp, L. MALPEAUX (*Soc. Aliment. Rationn. Bétail, Compte Rendu 10. Cong., 1906, pp. 9-13*).—The experiments reported and discussed have to do with the ensiling of beets and beet products, the extent and character of the losses sustained, and related topics.

According to the author, whole beets when ensiled may be kept in good condition, but, if kept for a long time, sustain a considerable loss, partly owing to the fermentation of carbohydrates and partly to the oxidation of organic material, which is transformed into carbon dioxide and volatilized. Cellulose is not the seat of such changes. Nitrogenous material is not lost, but becomes differently distributed, the albumins diminishing and the nonalbuminoid compounds increasing.

Sliced beets, chopped beets, and beet pulp sustain large losses when ensiled and mixing some absorptive material, like chopped hay, with the beet products does not remedy the matter. Drying is regarded as preferable for the chopped beets. In the case of the beet pulp, in the author's opinion, as much as possible should be fed while it is fresh.

Our lupines as a feeding stuff for farm animals (*Bol. Soc. Agr. Mericana, 31 (1907), No. 5, pp. 83-86*).—Analyses of lupines are given and the feeding value of these legumes discussed.

Gram as a stock feed (*Rhodesian Agr. Jour., 4 (1906), No. 1, pp. 56, 57*).—Gram (*Cicer arietinum*) is regarded in India as next to oats as a feed for horses, mules, sheep, and donkeys. It should not be fed until it is at least a month old and as it is very hard it should not be given whole to animals unless soaked.

"The morning and midday rations should soak all night, and the evening feed from early morning until required." The soaked material should be allowed to drain for half an hour before feeding, otherwise horses will sweat badly. Gram may also be ground, and in this case should be soaked for an hour and a half before feeding. "This softens the grain without causing it to ferment. Ground gram should never be soaked like the whole grain, as it ferments in the stomach when this is done, which means death to the horse or any other animal." Ten lbs. of gram per day is regarded as an ample ration for the small Rhodesian horses and is the amount fed to cavalry horses in India. Salt should always be fed with gram.

Grape marc as a feeding stuff, H. ASTRUC and E. BOUÇOIRAN (*Rcv. Vit., 26 (1906), No. 673, pp. 515-522*).—On the basis of experience and a summary of data recorded by other investigators, the feeding value of grape marc is pointed out.

Congress for the rational feeding of farm animals, proceedings (*Soc. Aliment. Rationn. Bétail, Compte Rendu 10. Cong., 1906, pp. 57-86*).—Routine business was transacted and papers were presented and discussed, among which were the following: The Use of Forage Crops which Generate Hydrocyanic Acid and the Seeds of Indian Vetch for Feeding Stuffs, by Mallevré, and The Employment of Denatured Sugar as a Feeding Stuff for Farm Animals, by Vivien. The author designated a mixture of sugar with a concentrated feed like corn meal and salt as "denatured sugar."

Types and breeds of farm animals, C. S. PLUMB (*New York and London: Ginn & Co., 1906, pp. X+563, pl. 1, figs. 256*).—This important volume, which is designed for the needs of live stock students, discusses breeds of horses, asses, mules, cattle, sheep, goats, and pigs. The better known breeds are discussed in more detail than those which are less well known, and a number of the breeds included, for instance, the ass, mule, and the Angora and milch goats, have not

generally received attention in text-books in English. A wide range of literature has been consulted in the preparation of the volume, and the discussion of each breed is followed by a list of reference works.

"During the past 20 years a great amount of evidence bearing on breed merit has been secured at the agricultural experiment stations, at expositions, on race courses, and at fair grounds. In the breed reviews in this work much of this recent evidence is given a place. Brief consideration is also given to some of the more important foundation families or tribes, and to individual animals that have made a deep impression upon the breed. The author has taken the liberty of commenting on the weak as well as on the strong points of the breeds, but this has been done in a nonpartisan spirit, in harmony with the views of capable critics.

"These brief studies of the types and breeds of farm animals are naturally far from complete. They are intended for the student or the stockman who sees the long road of education before him. The subject-matter is arranged with some regard to systematic grouping, with the hope that it may in a measure meet the requirements of the class room, the teacher, and the practical stockman on the farm."

The volume as a whole constitutes an important summary of available data regarding types and breeds of farm animals, and will prove generally useful to readers interested in the subject as well as to students of agriculture.

Farm animals in Montenegro, Bosnia-Herzegovina, and Dalmatia, A. PIROCCI (*Ann. Agr. [Italy], 1906, No. 246, pp. 155, figs. 34*).—A summary of statistical and other data regarding the production and management of farm animals in the Balkan states.

Balanced rations and the influence of nitrogen equilibrium on gains made by sheep, J. FABRE (*Ann. École Nat. Agr. Montpellier, n. ser., 6 (1906), Nos. 1, pp. 66-80, dgm.s. 2: 2, pp. 81-89*).—The digestible nitrogen supplied in the different experiments ranged from about 6 to 37.1 gm. per head per day. The balance of income and outgo of nitrogen was determined in the experiments and variations in weight were recorded. It was found that the rations furnishing the larger amounts of protein induced greater gains of nitrogen and larger gains in body weight.

Crossbreeding for mutton in the north of England, W. T. LAWRENCE (*Jour. Bd. Agr. [London], 13 (1906), No. 9, pp. 513-520, figs. 3*).—The general subject of crossbreeding mountain sheep for the production of mutton is discussed and some recent tests carried on by the author are briefly referred to.

In one test the Oxford-cross lambs matured more quickly and were less expensive than the other crosses. In the second test the Border-Leicester cross was regarded as preferable for fat lambs, though the Wensleydale cross was more satisfactory for the production of rapidly growing sheep for subsequent fattening.

As the author points out, "the wether lambs of the pure mountain breeds are allowed to take their time to grow and fatten on their native fells and do not come into the mutton market except as shearlings or two-shear sheep. A Herdwick two-shear fat wether is the acme of mutton production for quality and flavor."

The digestibility of barley grits by-products, F. BARNSTEIN and J. VOLHARD (*Landw. Vers. Stat., 65 (1906), No. 3-4, pp. 221-236*).—Using 2 sheep the digestibility of so-called barley feed meal, barley bran, and a by-product containing a very large proportion of the hull was studied. The basal ration was made up of meadow hay and cotton-seed meal and the digestibility of the feed-

ing stuffs under consideration was calculated in the usual way. The average coefficients of digestibility follow:

Digestibility of barley by-products—Experiments with sheep.

	Dry mat- ter.	Protein.	Fat.	Nitrogen- free ex- tract.	Crude fiber.
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Barley feed meal.....	90.7	72.2	37.5	99.3
Barley bran.....	76.7	84.6	87.2	86.0	20.3
Barley hull feed.....	67.4	88.7	97.6	73.1	31.2

The Arab horse, S. BORDEN (*New York: Doubleday, Page & Co., 1906, pp. XX+104, pls. 24*).—In his summary and discussion of data regarding Arab horses, the author has considered the early history of these horses, Arab horses outside of Arabia, Arab horses in America, and related questions.

A report on the horse-breeding industry of Wisconsin, A. S. ALEXANDER (*Wisconsin Sta. Bul. 141, pp. 162, figs. 39*).—The present condition of the horse-breeding industry is discussed as well as the effects and defects of the Wisconsin stallion law. The State law is quoted, with recommendations for new legislation. A directory is included of owners of licensed stallions, and a list of American and foreign stud books, as well as samples of the score cards used in the department of horse breeding at the Wisconsin College of Agriculture.

The State breeding-stock law, in the author's opinion, should be revised and should demand, among other things, the annual or biennial renewal of a license fee, and the adoption of a list of diseases to be considered "hereditary, transmissible, or communicable" and which would subject a stallion to rejection as unsound. Specific authority should be given for the department of horse breeding to refuse license to stallions known to be unsound and to revoke licenses granted to stallions since found to be unsound. There should also be authority to revoke the license of "scrub" stallions of "unknown breeding" and to refuse licenses to such horses in the future. The law should provide for State veterinary inspectors to inspect public service stallions and require State veterinary inspection of all stallions already granted licenses on the affidavit of the owner.

The use of artichokes as a feeding stuff for work horses, MAGEN (*Soc. Aliment. Rationn. Bétail, Compte Rendu 10. Cong., 1906, pp. 87, 88*).—Having noted that the peasants in southern France are in the habit of feeding Jerusalem artichoke tubers to work horses the author studied the feeding value of this material and obtained satisfactory results with a number of draft animals. In his opinion not over 12 liters of chopped artichokes should be fed. The artichokes were mixed with crushed grain and 10 to 15 liters of chopped hay which absorbs the moisture.

According to the author, when artichokes were thus substituted for barley or oats for 100 days no unfavorable results were noted. The ration is recommended as being very economical, both on account of the small value of the land on which the artichokes are grown and the ease with which the plant may be cultivated.

An approximate law of fatigue in the speeds of racing animals, A. E. KENNELLY (*Proc. Amer. Acad. Arts and Sci., 42 (1906), No. 15, pp. 275-331, figs. 15*).—As the author points out, an athlete, whose limit of racing speed is 100 yds. in 10 seconds, that is, who is physically exhausted by such an effort, can not run 200 yds. in 20 seconds. The fastest rate which can be maintained in order to complete the longer run, that is, which will just produce exhaustion at the end of the 200 yds., is obviously lower, and it is this value which the author has sought to determine by a study of various national and international racing

records and similar data collected for trotting, pacing, and running horses, as well as for men running, rowing, skating, and swimming.

From the data summarized a number of general deductions are drawn, from which the following are quoted:

"The time varies approximately as the ninth power of the eighth root of the distance. Doubling the distance means increasing the time 118 per cent.

"The time occupied in a record-making race varies approximately inversely as the ninth power of the speed over the course. Doubling the speed cuts down the racing time 512 times.

"The distance covered increases approximately as the eighth power of the ninth root of the time. Doubling the time of the race allows of increasing the course length by 85 per cent.

"The distance covered increases approximately as the inverse eighth power of the speed over the course. Doubling the speed cuts down the distance that can be covered 256 times.

"The speed over the course varies approximately as the inverse eighth root of the distance. Doubling the distance brings down the speed about 9.3 per cent.

"The speed over the course varies approximately as the inverse ninth root of the racing time."

The mule and its uses, J. L. JONES (*Breeder's Gaz.*, 50 (1906), No. 8, pp. 325-327, figs. 2; 9, p. 367; 10, pp. 414, 415; 11, pp. 650, 651, figs. 2; 26, pp. 1418, 1419, figs. 3).—The history of mule raising, methods of breeding, feeding, care and management of mules, and related questions are discussed on the basis of experience. According to the author, unshelled corn, ground barley, shelled oats, bran, corn, and similar materials are satisfactory feeds for mules and should be used in conjunction with hay and corn forage. Salt should be given regularly. Hulled oats and bran are regarded as essentials for fattening mules and for producing a fine coat.

Animal food for poultry, H. DE COURCY (*Jour. Bd. Agr. [London]*, 13 (1906), No. 8, pp. 457-461).—The value of different sorts of animal feed and related questions are considered.

"Fowls kept in confined runs should have an ample supply of animal food. This is not only necessary in order that they may lay good number of eggs, but also to prevent egg eating and feather pulling. These depraved habits are usually indulged in by fowls which are confined and fed on too carbonaceous a diet. In such conditions, fowls have an insatiable craving for animal food, or, in other words, for more protein, and they strive to satisfy the desire by eating their own eggs and plucking out and swallowing the feathers from each other's bodies."

The ostrich feather industry (*Brit. Trade Jour.*, 45 (1907), No. 529, pp. 17-19, figs. 4).—Breeding, feeding, and handling ostriches, feather plucking, and related questions are discussed. On the basis of personal experience, the author states that the eggs are very satisfactory for food purposes, being usually cooked in the form of omelettes. A native method is to cook the whole egg in the hot ashes of a fire built in a shallow hole in the ground.

DAIRY FARMING—DAIRYING—AGROTECHNY.

Feeding experiments with milch cows, J. HANSEN (*Landw. Jahrb.*, 35 (1906), Sup. 4, pp. 327-369).—Various feeding stuffs were compared in tests with 10 cows covering a period of 149 days. The work is a continuation of experiments previously noted (E. S. R., 17, p. 901).

Among the conclusions reached are the following: Feeding stuffs exert a

specific influence on milk production independent of the amount of nutrients they contain. This is manifested to some extent in the yield of milk, but more particularly in the fat content of the milk. The yield of milk is less favorably influenced by sesame cake, poppy-seed cake, and cotton-seed meal than by peanut cake, and more favorably by rape-seed cake than by peanut cake. Coconut cake, palm-nut cake, linseed cake, and peanut cake have about the same influence. None of the differences, however, are considered of importance.

The percentage of fat in the milk is increased by palm-nut cake, coconut cake, and cotton-seed meal, and decreased by poppy-seed cake as compared with peanut cake. Linseed cake, sesame cake, and rape-seed cake have the same influence as peanut cake. Rice meal exerts an unfavorable influence on the fat content of the milk.

As compared with peanut cake the daily yield of fat was, therefore, increased by coconut cake, palm-nut cake, linseed cake, cotton-seed meal, and rape-seed cake, and decreased by sesame cake, poppy-seed cake, and rice meal.

Demonstration experiments on the feeding of dairy cows, conducted at the expense and under the supervision of the government during the winter of 1905-6 (*Bul. Agr. [Brussels], 22 (1906), No. 6, pp. 657-822*).—This is a detailed report of numerous feeding experiments carried out in the different provinces of Belgium in the same manner as in previous years (*E. S. R., 17, p. 693*).

Feeding experiments with dried beet leaves, W. WREDE (*Deut. Landw. Presse, 84 (1907), No. 5, p. 32*).—This material was compared with brewery residue in a test with 51 cows lasting 21 days, the results indicating that 1 kg. of the residue may be replaced by 1.5 kg. of the dried beet leaves. The dried leaves were also compared with beet-leaf silage in a test with 49 cows lasting 32 days, the results indicating that 1 kg. of the former is equivalent to 5 kg. of the latter.

The influence of the condimental feed Enzymol upon the milk production of cows, M. DURÉ (*Ztschr. Landw. Versuchsw. Österr., 9 (1906), No. 11, pp. 1003-1014*).—In tests with 6 cows this material apparently prepared from yeast tended in nearly every instance to decrease the yield of milk. It was without influence upon the fat content of the milk, the amount of other feed consumed, or the live weight of the animals.

Tests of Swiss, Simmental, and East Friesian cows, J. HANSEN (*Landw. Jhrb., 35 (1906), Sup. 4, pp. 147-326, pls. 6*).—This is a detailed report of tests of 13 Swiss, 12 Simmental, and 14 East Friesian cows. The Swiss cows weighed on an average 567 kg. and produced during 1 year 5,150.04 kg. of milk and 185.33 kg. of fat; the Simmental cows weighed 659 kg. and produced 5,565.22 kg. of milk and 225.42 kg. of fat; and the East Friesian cows weighed 559 kg. and produced 6,451.75 kg. of milk and 199.31 kg. of fat. The data obtained are discussed from various standpoints and compared with similar data for other breeds.

Milk production and breast girth, E. SCHNABEL (*Österr. Molk. Ztg., 14 (1907), No. 1, pp. 2, 3*).—Comparing cows of the same age and stage of lactation a higher yield of milk was associated with a greater breast measure in 23 out of 34 comparisons and with a smaller girth in 7 comparisons. In 4 comparisons the girth was the same, but the yield different.

The development of the testing of cows by control associations, PETERSEN (*Illus. Landw. Ztg., 27 (1907), Nos. 5, pp. 29-32; 6, pp. 37, 38*).—This is a discussion of the progress made in Germany along this line.

The milking machine as a factor in dairying (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 92, pp. 55, pls. 4, figs. 6*).—This is a preliminary report on investi-

gations of the milking machine from the standpoints of actual practice and of bacteriology.

Practical studies of a milking machine, by C. B. Lane (pp. 9-32).—The author describes several milking machines, gives estimates of the cost of equipment for machine milking, reports in detail two experiments in which hand milking and machine milking were compared, discusses the effects of milking machines upon the cows and other problems, and in conclusion summarizes the results of experience with milking machines as reported by dairymen.

The first test reported was made with 8 cows and lasted 30 days. The herd of 13 cows from which the 8 were selected had been milked with machines for over 3 years. The second test, lasting 20 days, was made with 20 cows selected from a herd of 65 with a view to securing cows of different kinds, including hard and easy milkers, heifers and mature animals, cows in the first and last stages of lactation, and cows of nervous temperament.

In the first test the time required for milking 4 cows twice daily by hand averaged 40.59 minutes and by machine 26.59 minutes. The difference in yield of milk, not including strippings, was 3.9 per cent in favor of machine milking. Hand milking was less thorough than machine milking as an average of 4.55 oz. of strippings per cow for each milking was obtained in the former case, and 4.12 oz. in the latter.

In the second test the time required for milking 10 cows twice daily by hand averaged 154.9 minutes and by machine 37.07 minutes. The difference in yield of milk, not including strippings, was 7.59 per cent in favor of hand milking. The strippings per cow at each milking averaged 2.7 oz. in case of hand milking and 3.4 oz. in case of machine milking. The average fat content of hand-drawn milk was 3.77 per cent and of machine-drawn milk 3.49 per cent.

The author offers a number of suggestions for the improvement of milking machines and points out the objections and difficulties to their use as well as their advantages. The need of further investigation is emphasized.

The experience of 11 dairymen who made reports was favorable to machine milking as compared with hand milking.

Bacteriological studies of a milking machine, by W. A. Stocking, jr. (pp. 33-55).—The results are summarized by the author as follows:

"(1) Unless sufficient care is used in cleaning the machines, decaying milk and bacteria accumulate in the rubber tubes and contaminate the milk as it passes through them.

"(2) The few dairymen now using these machines are not exercising sufficient care in washing and sterilizing the machines to keep them in sanitary condition; their milk is therefore of poorer quality from the sanitary standpoint than that drawn by hand under the same stable conditions.

"(3) Good sanitary conditions in a stable may be completely counteracted by the insanitary condition of the milking machine.

"(4) When kept in fairly clean condition the machine-drawn milk contains decidedly smaller numbers of bacteria than the corresponding hand-drawn milk.

"(5) When the machines are not well cleaned both the number and percentage of acid-producing bacteria are higher than in the hand-drawn milk, but when they are fairly well cleaned both the total number and the percentage of these bacteria are decidedly lower than in the corresponding hand-drawn milk.

"(6) Both the total number and the percentage of liquefying bacteria found in the milk were in most cases greatly reduced by the use of the machines. This fact is of special significance in milk designed for direct consumption.

"(7) When properly cared for, drawing the milk by means of the machine increases its keeping quality.

" (8) Washing the machines with cold water and then with hot water containing sal soda is not sufficient to keep the rubber tubes clean. Under this treatment the inside of the tubes becomes coated with decaying milk, thus forming ideal conditions for the multiplication of various species of bacteria.

" (9) Scalding the machines by pumping boiling water through them just before use had little or no effect in reducing germ content of the milk.

" (10) Boiling in clear water for three-quarters of an hour was not sufficient to keep the rubber tubes in a sterile condition.

" (11) Subjection to steam without pressure for 30 minutes was not sufficient to sterilize the rubber tubes.

" (12) Placing the rubber parts in brine for several hours after being washed reduced the germ content of the machine-drawn milk to about one-half that of the milk drawn by hand.

" (13) Boiling in water containing a small amount of powdered borax had about the same effect in reducing the bacterial content of the milk as did the brine treatment, but the use of borax is dangerous unless extreme care is exercised.

" (14) The machines may be very effective in the production of sanitary milk if they are properly cleaned and sterilized.

" (15) The results of these experiments indicate that the machines may be kept in such an insanitary condition that the keeping quality will not be improved, but may be seriously impaired. They also indicate that with properly cleaned and sterilized machines the keeping quality of the milk may be very materially improved."

The variation in the composition of milk, A. LAUDER (*Edinb. and East of Scot. Col. Agr. Bul. 11, pp. 52*).—Causes of variation in the composition of milk are briefly discussed, and the results of a systematic examination of the milk of two well-kept private dairy herds in the East of Scotland are reported. The investigation with one herd of 22 cows began in May, 1905, and is being continued. Another herd of 30 cows was tested from June to October, 1905. Both herds were of the dairy Shorthorn type.

The average composition of the mixed milk of the smaller herd for 1 year was 12.34 per cent of total solids and 3.15 per cent of fat for the morning's milk, and 12.96 per cent of total solids and 3.91 per cent of fat for the evening's milk. The cows were milked at 6.30 a. m. and 4 p. m. During the months of February, March, and April, the milk of individual cows fell below the legal standard of 3 per cent of fat 99 times in the morning and 45 in the evening. When the cows were milked at equal intervals for a short period the differences in percentages of fat and total solids between the morning's and evening's milk were much reduced. Increasing the amount of feed had practically no effect on the fat content of the milk.

The average composition of the mixed milk of the other herd was 12.83 per cent of total solids and 3.95 per cent of fat for the morning's milk and 12.77 per cent of total solids and 3.88 per cent of fat for the evening's milk, but here the intervals between milkings were equal.

Opsonins in milk, G. S. WOODHEAD and W. A. MITCHELL (*Jour. Path. and Bact., 11 (1907), No. 4, pp. 408-414*).—Using human leucocytes the opsonic index of the blood of a nontuberculous cow was found to be 0.8 and that of the milk 0.6. The figures in another case were, respectively, 0.96 and 0.57. The milk of an apparently healthy cow showed an opsonic index of 2.2, while the indices of the milk of 3 cows in a comparatively low state of health were, respectively, 0.51, 0.44, and 0.48. The opsonin content of whey prepared by either rennet or hydrochloric acid was found to be greater than that of an equal volume of

milk, indicating, in the opinion of the authors, that the gastric secretions are not likely to lower the activity of the opsonins. The opsonic indices of milk, rennet whey, and whey prepared by adding hydrochloric acid in several experiments were, respectively, 0.72, 1.03, and 1.2.

It is considered possible that the high opsonic index of milk may play an important part in protecting young children against tuberculosis.

The heat value of milk as a test of its quality, J. MALCOLM and A. A. HALL (*Jour. Agr. Sci.*, 2 (1907), No. 1, pp. 89-95).—Experiments were conducted to determine the value of the direct estimation of the caloric value of milk by combustion in a bomb calorimeter as a practical means of judging the quality of milk. The process is said to require little chemical knowledge, to be easily learned, very accurate, and to occupy a relatively short time.

The results show a general relationship between the percentages of fat or total solids and the caloric value. The method is, therefore, considered an important means of detecting the removal of fat and estimating total solids. It is suggested that the legal definition of milk might be improved by the adoption of a minimum caloric value. While the determinations so far made are too few for establishing a standard, it is estimated that in order to correspond with the present legal standard in Great Britain it should not be below 650 calories per cubic centimeter, or 5,650 calories per gram of solids.

Fermentation of milk, F. BLUMENTHAL and WOLFF (*Abs. in Jour. Chem. Soc.*, [London], 90 (1906), No. 539, p. 879).—It is stated that milk kept for years may contain 50 per cent of the lactose originally present. Proteids are not peptonized in spontaneous acid fermentation, but large amounts of amino acids are formed. Tryptophan is also present. Prolonged putrefaction increases the lactic acid more than the succinic acid.

Comparative investigations on the lactic-acid bacteria of the *Bacterium gūntheri* type from different sources, L. MÜLLER (*Centbl. Bakt.* [etc.], 2, *Abt.*, 17 (1906), Nos. 14-16, pp. 468-479; 19-21, pp. 627-633; 17 (1907), No. 22-24, pp. 713-755).—With one exception, the several cultures of *Bacterium gūntheri* studied showed no essential difference in morphological or cultural characteristics.

The prolonged culture of these organisms on a suitable medium failed to influence to any marked extent their acid-producing power. A close relationship was observed between *B. gūntheri* and *Streptococcus agalactiv* as regards morphology and ability to ferment different sugars. When grown on certain media, *B. gūntheri* resembled the streptococcus and when grown on other media the reverse was true. This explains, according to the author, the frequency with which the two forms have been confused. A streptococcus isolated from mastitis assumed in cultures forms resembling in different degrees lactic-acid bacteria.

Some investigations and observations on lactic-acid bacteria, T. GRUBER (*Centbl. Bakt.* [etc.], 2, *Abt.*, 17 (1907), No. 22-24, pp. 755-760).—Studies of a number of cultures of lactic-acid bacteria isolated from dairy products are briefly reported. The morphological and cultural characteristics heretofore used in distinguishing forms of lactic-acid bacteria are considered of little value. It is considered important to determine the behavior of the different races of lactic-acid bacteria toward milk sugar, dextrose, mannite, maltose, etc.

Aroma-producing bacteria in milk, J. VAN DER LECK (*Centbl. Bakt.* [etc.], 2, *Abt.*, 17 (1906), Nos. 11-13, pp. 366-373; 14-16, pp. 480-490; 19-21, pp. 647-660).—The author reports an extended study of *Bacillus aromaticus* in comparison with other organisms, from which he concludes that this bacillus plays an important rôle in the ripening of soft cheese. The work is being con-

tinued. Methods of studying this subject and results obtained by other investigators are discussed.

A note on the coagulation of milk by *Bacillus coli communis*, C. J. O'HEHR (*Jour. Path. and Bact.*, 11 (1907), No. 4, pp. 465-467).—Experiments by the author confirm the view previously expressed that the coagulation of milk by *Bacillus coli communis* is due to the production of an acid, presumably lactic, by the bacteria. While the subsequent formation of an enzyme rendering the coagulum insoluble may be common it is not considered universal.

Development of factory dairying in Wisconsin with map showing location of cheese factories and creameries, H. L. RUSSELL and V. S. BAER (*Wisconsin Sta. Bul.* 140, pp. 18, pl. I, map 1).—The station has issued at intervals of 5 years a map of Wisconsin upon which is marked the location of each factory in the State. The series, therefore, furnishes valuable data concerning the growth of the industry.

The bulletin which the present wall map accompanies discusses the relation of factory development to dairy development, the causes of the reduction in the number of creameries, the growth and output of cheese factories, and the regions of marked dairy factory activity which are designated the Swiss-cheese region, Richland County Cheddar region, Cheddar region of lake-shore and adjacent counties, brick cheese region of Dodge County, butter center of southeastern Wisconsin, and the new dairy region of central Wisconsin.

“While a study of this sort can not be taken as final evidence of the state of dairy development, a comparative study of the growth of creameries and cheese factories during the last five years shows a progressive development that bespeaks a healthy condition for the dairy industry. During the last 5 years the number of cheese factories has increased about 7 per cent, aggregating now 1,649 with 40 factories in addition that make both cheese and butter. The creameries have diminished some in number, because of the extension of the operating radius of the creamery through the conversion of many creameries into skimming stations. The introduction of the farm separator, and the natural centralization or syndicating of factories have been the main causes for the reduction of creameries. There are now 1,017 creameries and 260 skimming stations. . . .

“On the whole, factory growth is going on rapidly throughout most regions of the State. Not only is the number actually increasing, but the average output is much larger than formerly, while the aggregate amount of dairy products manufactured has increased in the last 5 years over one-half in the case of butter, and has nearly doubled in the case of cheese.”

Efficiency of cream separators under farm conditions, I. P. WHITNEY (*Oregon Sta. Bul.* 89, pp. 3-10).—Notes are given on the history of the cream separator and its efficiency with special reference to farm conditions is discussed. Comparative tests of different separators conducted in the fall and again in the spring are reported.

The author concludes that the farm cream separator is a thoroughly practical machine and much more effective than any of the gravity methods. The separation of the cream was more thorough in the spring when the cows were pastured, than in the fall when fed dry feed. The average fat content of skim milk under the two conditions was respectively 0.02 and 0.045 per cent. The different sizes of separators were about equally efficient. No information of particular value regarding the durability of the different separators was secured.

Dairy school cream separator tests, F. L. KENT (*Oregon Sta. Bul.* 89, pp. 10-17, figs. 7).—Tests of 7 makes of cream separators by students during 4

years are reported, as are also similar tests by the author, assisted by W. W. Grant, special dairy instructor, made with a view to securing data regarding the accuracy of the students' tests. The results showed that it would be necessary to separate about 5,000 lbs. of milk in order to make a difference of 1 lb. of fat, lost in the skim milk between the most efficient and the least efficient machine tested. Notes are also given on the advantages and disadvantages of the machines.

The hand separator and the gravity systems of creaming, O. F. HUNZIKER (*Indiana Sta. Bul. 116, pp. 341-364, figs. 10*).—The purpose of the work reported in this bulletin, as stated in the introduction, was to determine the skimming efficiency of the various systems of creaming; to study the effect of these systems on the quality of the cream and skim milk; to determine the influence of such factors as the steadiness of running and the care of the machine, the speed of the bowl, the temperature and physical condition of the milk, the rate of inflow and the richness of the cream, on the skimming efficiency of the hand separator; and to point out to Indiana dairymen those methods and conditions that will reduce the loss of butter fat in skim milk to the minimum and improve the quality of the cream.

The author summarizes the results obtained as follows:

"The use of the hand separator in the place of the gravity systems of creaming will effect a saving of \$3.50 to \$7 worth of butter fat from one cow in one year.

"With the hand separator a richer cream and a better quality of cream and skim milk can be produced than with the gravity systems.

"Of the gravity methods the deep setting system is the least objectionable. It produces a more complete separation and a better quality of cream than either the shallow pan or the water dilution systems.

"Any neglect to thoroughly clean the separator after each separation reduces the skimming efficiency of the machine and lowers the quality of the cream and butter produced. Wash the separator after each separation.

"A trembling machine, insufficient speed, sour, curdled, slimy, or cold milk, and overfeeding the separator caused a loss of butter fat in the skim milk amounting to from 8 to 12 lbs. of butter per cow in one year.

"Other things being equal, high speed and a small rate of inflow tend to produce a thick cream. Insufficient speed, a trembling machine, and a large rate of inflow result in a thinner cream."

The evolution of gas during churning, R. D. WATT (*Jour. Agr. Sci., 2 (1907), No. 1, pp. 96-99*).—According to the author's conclusions a considerable quantity of carbon dioxid is produced by bacteria during the ripening of cream. This gas which is held in a state of supersaturation is liberated to a large extent during the beginning of the churning process. The amount of carbon dioxid produced was found to bear no very constant relation to the lactic acid or to the total acidity.

The constants of bog-butter found in the peat of Ireland, L. G. RADCLIFFE and W. H. MADDOCKS (*Jour. Soc. Chem. Indus., 26 (1907), No. 1, p. 3*).—The analyses of 2 samples reported show the changes undergone by butter preserved, possibly for centuries, in peat water.

On the cause of a brown-red coloration of hard and soft cheese, T. GRUBER (*Centbl. Bakt. [etc.], 2, Abl., 17 (1907), No. 22-24, pp. 761-764*).—The author gives the morphological and cultural characteristics of *Bacterium casei fusci*, which was found to be the cause of this fault in cases under investigation.

On some phenomena observed in the peptic digestion of caseins, J. H.

LONG (*Jour. Amer. Chem. Soc.*, 29 (1907), No. 2, pp. 223-230).—Preparations of casein from cow's milk and goat's milk were compared as regards their digestibility with pepsin and dilute hydrochloric acid. The two forms were found to be very much alike in general behavior. The artificial digestion of the casein from goat's milk was much slower than that of the casein from cow's milk. Other points of difference were observed, the most marked of which was the larger amount of the so-called pseudo-nuclein obtained from the casein from goat's milk.

The fermentations of casein and their applications, A. RODELLA (*Arch. Hyg.*, 59 (1906), No. 4, pp. 337-354, pls. 2).—The author maintains as the result of his investigations that the fermentations of casein are dependent upon anaerobic bacilli. These give rise to a large number of products, including volatile fatty acids. Aerobic bacteria, such as *Bacillus subtilis*, *B. megatherium*, and *B. mycoides*, may, however, decompose casein, but no volatile fatty acids are produced.

The anaerobic fermentation of casein is marked by the appearance of a black color, due to the formation of an inorganic compound containing iron and sulphur, although this may not appear if the medium is acid. The control of anaerobic fermentation in cheese ripening by the addition of acid or salt is therefore desirable. The significance of aerobic tyrothrix forms in the ripening of cheese is considered entirely different from that of the anaerobic forms, and the two classes of organisms should not, therefore, be grouped together. It is suggested that a satisfactory classification of the different varieties of cheese might be based upon anaerobic fermentations.

Casein: Its preparation and technical utilization, R. SCHERER, trans. by C. SALTER (*London: Scott, Greenwood & Son; New York: D. Van Nostrand Co.*, 1906, pp. XI+168, figs. 11).—This is the translation of the German edition to which reference has already been made (E. S. R., 17, p. 400). The book deals with the preparation and properties of casein and its use as a painting material, as a mucilage or cement, as a substitute for horn, ivory, celluloid, etc., as a dressing for textiles, as a foodstuff, and for other purposes. A summary is also given of the known compounds of casein.

Annual report on the investigations and progress in sugar making, J. BOCK (*Jahresber. Zuckerfabrik. [Stammer]*, 45 (1905), pp. X+321).—This report for 1905 is similar in character to the preceding one (E. S. R., 17, p. 907).

Cane juice defecation, 1905, W. L. BASS, trans. by S. F. DE VELASCO (*New York: Polydore Barnes Co. Press, 1905, pp. 205, pls. 2, figs. 39*).—This subject is treated in simple language for the use of managers and others engaged in practical sugar making. The text is in both English and Spanish.

The influence of sulphurous acid, free and in combination with acetaldehyde, on the different organisms in wine, W. SEIFERT (*Ztschr. Landw. Versuchsw. Österr.*, 9 (1906), No. 12, pp. 1019-1059).—This gives the results of an extended investigation on the amount of sulphurous acid free and in combination with acetaldehyde in wine resulting from fumigation with sulphur fumes, and the influence of each form on yeast, fungi, and acetic-acid bacteria.

The methods of examination and the organisms of vinegar and the materials from which made, F. ROTHENBACH (*Die Untersuchungsmethoden und Organismen des Gärungsessigs und seiner Rohstoffe*, Berlin: Paul Parey, 1907, pp. XI+237, figs. 118).—The first part of this treatise takes up some of the elementary principles of chemistry and then details methods for such determinations as alcohol and acetic acid. The second part describes the organisms concerned in vinegar making and discusses their use.

VETERINARY MEDICINE.

Special pathology and therapy of domestic animals, F. HUTYRA and J. MAREK (*Spezielle Pathologie und Therapie der Haustiere. Jena; Gustav Fischer, 1905, vol. 1, pp. XI+873, pls. 3, figs. 132; 1906, vol. 2, pp. X+971, figs. 138*).—The basis of this work was first published in Hungarian by the senior author.

In its present form it covers in great detail the essential points in connection with all of the common diseases affecting farm animals. The subject matter is arranged according to the usual systematic plan, viz. infectious diseases of general, exanthematic, or local character, and of an acute or chronic nature, whether caused by bacteria or protozoa, and organic diseases classified according to the part or structures affected. The etiology, pathology, and treatment of these diseases are thoroughly discussed and well illustrated.

Notes on blood-serum therapy, preventive inoculation, and toxin and serum diagnosis for veterinary practitioners and students, W. JOWETT (*Chicago: W. T. Keener & Co., 1907, pp. VII+204, figs. 37*).—The subjects discussed in this volume have, within recent years, assumed such importance and made such great advancement in practical application in the diseases of animals that a handbook covering the technical details of this work was needed for laboratory investigators and veterinary practitioners.

The present volume contains an account of the three prominent theories of immunity, methods of conferring immunity, diseases due to ultraviolet virus, diseases caused by the protozoa, and diagnosing by means of toxins and serums. The essential points are presented in a remarkably clear and concise manner and convey effectively the information which the laboratory worker or practitioner needs along this line.

Killing and attenuating micro-organisms by chemically indifferent bodies, E. LEVY ET AL. (*Centbl. Bakt. [etc.], 1. Abt., Orig., 42 (1906), No. 3, pp. 265-270*).—In most schemes of attenuation materials or methods are used which may change the chemical composition of the bacteria and may, therefore, render them less capable of exercising a vaccinating effect. The authors therefore decided to test the effect of indifferent bodies in attenuating bacteria without changing their chemical composition or interfering with their vaccinating powers. For this purpose sugar and glycerin were selected, preference being given to sugar on account of the fact that the bacteria in a sugar solution could be readily dried at any desirable time.

It was found in the experiments carried out by the authors that the attenuating effect of either sugar or glycerin was considerably increased by maintaining the cultures in an apparatus in which they could be continually shaken. In working with tubercle bacilli it was found that a temperature of 37° C. in an 80 per cent solution of glycerin was sufficient to produce a pronounced attenuation within 5 days. Guinea pigs were inoculated with tubercle bacilli which had been treated in this way and subsequently received cultures treated for shorter periods ranging from 4 days down to 1 day. Animals treated in this way were found to be immune to fatal doses of virulent tubercle bacilli.

The same method was tried with glanders bacilli, the organisms being shaken for from 13 to 72 hours in an 80 per cent glycerin solution at a temperature of 37° C. Large doses of glanders bacilli treated in this way produced a complete immunity against 4 to 5 times the fatal dose of virulent glanders bacilli. The first experiments were carried out on guinea pigs, but later 5 horses were treated in the same way and proved to be immune to glanders.

The method will be tested on a number of other pathogenic organisms.

Annual report on the distribution of animal plagues in the German Empire (*Jahresber. Verbr. Tierseuch. Deut. Reichs*, 20 (1905), pp. VIII + 210, pls. 4, figs. 19).—A discussion is presented of the extent and distribution of all the important animal diseases in the German Empire, including particularly anthrax, blackleg, rabies, glanders, foot-and-mouth disease, pleuro-pneumonia, mange, tuberculosis, and infectious diseases of hogs and poultry.

Details concerning the distribution of these diseases in different parts of the German Empire are presented in tabular form. The recent meat inspection regulations of Germany are given and a brief outline is presented of laws relating to animal diseases in various countries.

Notes from the Berlin medical clinic, E. FRÖHNER (*Monatsh. Prakt. Tierheilk.*, 18 (1906), No. 3-4, pp. 134-137).—A number of cases which came under the observation of the author are reported. In one instance a case of tetanus which had developed in a horse as a result of docking was not checked by the amputation of the tail. The only result of this operation was to delay the death of the animal for a few days.

Notes are also given on intermittent lameness in horses as a result of sarcoma in the mediastinal space, on chronic nephritis following hemoglobinuria, mercuric poisoning in horses, abscesses of the spleen, and tuberculosis in the horse complicated with pneumonia. This combination of tuberculosis and pneumonia is of very rare occurrence.

Veterinary hygienic principles applicable to stock in South Africa, A. THEILER and C. E. GRAY (*Transvaal Agr. Jour.*, 5 (1906), No. 17, pp. 96-110, pl. 1).—Attention is called to the highly contagious nature of sheep scab and the ravages which it has caused. An improved sheep-dipping vat is illustrated and described by T. H. Dale. Brief accounts are also presented of epizootic lymphangitis, hog cholera, and mange in horses.

New treatment of serious wounds and injuries, particularly synovial lesions by crystallized boric acid, BUSY (*Rec. Méd. Vét.*, 83 (1906), No. 17, pp. 623-627).—In the author's experience the best results have been obtained from the use of pure boric acid by means of which a complete acidification and saturation of wounds and surrounding tissue are accomplished in such a way as to relieve the inflammation of the affected part. This treatment not only allays inflammation but acts as a local anesthetic and is particularly well adapted for use in cases of injury to the joints or tendons.

An apparatus for the intravenous injection of large quantities of fluids, W. FLATTEN (*Berlin. Tierärztl. Wchnschr.*, 1906, No. 38, pp. 697, 698, fig. 1).—The chief features of the apparatus described by the author are a graduated glass cylinder, rubber tube, clamp for holding the apparatus firmly attached to the animal's neck, and the needle which penetrates into the blood vessel. The advantages claimed for the apparatus are that it is easily cleansed and that the operation is simple.

Tuberculosis: Its origin and extinction, W. P. TURNER (*London: Adam & Charles Black*, 1906, pp. XII + 96, pls. 4, figs. 18).—A general plan, believed by the author to be novel and original, is suggested for the eradication of tuberculosis in man and animals.

The author holds, in the first place, that tuberculosis in man is acquired always by ingestion or inoculation and never by inhalation, and that the disease is derived primarily from cattle. Cattle in turn are believed to be infected from eating forage contaminated with the tubercle bacillus. It is also maintained that the tubercle bacillus is naturally a saprophyte, and that it only becomes pathogenic when protected from the actinic rays of the sun. The author's scheme, therefore, for the total eradication of tuberculosis con-

sists simply in providing all cattle barns with glass roofs in order to expose them to the action of the sun.

The relation of tuberculous lesions to the mode of infection, E. C. SCHROEDER and W. E. CORTOX (*U. S. Dept. Agr., Bur. Anim. Indus. Bul.* 93, pp. 19).—The experiments reported in this bulletin were carried out chiefly to obtain evidence as to the susceptibility of the lungs to infection with tubercle bacilli without regard to the point of inoculation. The work was in continuation of similar investigations already reported (*E. S. R.*, 18, pp. 82, 378).

In these experiments 3 hogs and 2 calves were given subcutaneous injections of virulent tubercle bacilli in the tip of the tail. This point was selected as being farthest removed from the lungs. A study of these cases showed that the tubercle bacilli were taken up either by the capillary blood vessels or by the lymphatic system and were carried to the lungs, which became excessively diseased in all cases, while the inguinal glands, liver, and spleen were affected to a less extent.

It appears, therefore, that the inhalation theory, to explain the frequent infection of the lungs in tuberculosis, is becoming more and more unsatisfactory, and more evidence is being accumulated for the belief that tuberculous infection reaches the lung as well as other organs through tubercle bacilli taken with the food. These conclusions are believed to apply both to animals and man.

Tubercular infection, W. T. D. BROAD (*Vet. Rec.*, 19 (1906), No. 955, p. 252).—The author raises an objection to the frequent statement that direct experiments in the transmission of tuberculosis from animals to man are impossible. He argues that many instances are known where such transmission has taken place through the agency of milk and considers the evidence in some of these cases as very conclusive. One instance is cited.

The investigations of Dammann and Müssemeier on the relation between human and bovine tuberculosis, H. KOSSEL (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 42 (1906), Nos. 5, pp. 491-495; 6, pp. 489-495).—The author reviews in a critical manner the experimental data and the conclusions drawn from them in the investigations of Dammann and Müssemeier.

It is believed that the conclusions as to the unity of tubercle bacilli rest upon the assumed impossibility of determining constant morphological differences between tubercle bacilli obtained from different sources and also upon the apparent similarity of different races of bacilli in so far as pathogenic action is concerned. The author argues that these facts are not demonstrated and that, therefore, the conclusions as to unity of the different races of bacilli should not be drawn.

Tubercle bacilli in the apparently unaltered lymph glands of tuberculous animals, J. SWEINSTRÄ (Ztschr. Fleisch u. Milchhyg., 17 (1906), No. 2, pp. 27-42).—In the investigations reported by the author guinea pigs, rabbits, goats, pigs, and calves were used as experimental animals. A careful examination was made of apparently normal lymph glands in these animals after they had been infected with tuberculosis, the animals being inoculated with material from the glands of hogs to determine the presence or absence of tubercle bacilli. Positive results were obtained for tubercle bacilli in 7 cattle and 2 hogs, while negative results were obtained in the case of 11 cattle and 6 hogs.

As a result of this study, the author recommends the sterilization of the meat in all cases of tuberculosis in which great emaciation is seen, in all cases with extensive softened foci, in cases showing a recent blood infection, and in tuberculosis of the bones.

Primary tuberculosis of the larynx, H. HOLTERRBACH (*Deut. Tierärztl. Wchuschr.*, 14 (1906), No. 44, pp. 541, 542).—Tuberculosis of the larynx in the primary form is not of common occurrence. On this account the author describes in detail an undoubted case in a cow resulting in death after 1 year and causing a complete loss of voice, which persisted for 10 months before death. The tuberculous infection in the region of the larynx was of an acute and rapidly extending nature, but there were no lesions in the lungs or even in the lymph glands in the region of the larynx.

Immobility in cattle as a result of tuberculosis, E. BESNOIT (*Rev. Vét. [Toulouse]*, 31 (1906), No. 11, pp. 701-710).—Considerable attention has been given by the author to cases of tuberculosis affecting the brain and causing some form of meningitis which results in a loss of the power of motion on the part of the affected animal. In the cases which have come under his observation there were tuberculous lesions in the lungs and other organs and the cerebral symptoms were so pronounced as to indicate serious lesions in the brain.

Cases of apparent recovery from experimental tuberculosis, L. MARTIN and A. VAUDREMER (*Compt. Rend. Soc. Biol. [Paris]*, 61 (1906), No. 28, pp. 260-262).—As a result of treatment with tubercle bacilli from which the fatty substances had been removed, apparent recoveries took place in rabbits, but in some cases the tubercles which apparently had healed subsequently showed virulence. The authors, therefore, recommend caution in experiments of this sort to avoid mistakes of judgment after the use of tubercle bacilli of low virulence.

The actual status of vaccination and serotherapy for tuberculosis, G. MOUSSU (*Rec. Méd. Vét.*, 83 (1906), No. 21, pp. 741-758).—In this article the position is taken that the views commonly expressed regarding the present methods of serotherapy for tuberculosis are much too optimistic. The author expresses the opinion that a reliable method of treatment is still to be found.

Quantitative relations of agglutination of tubercle bacilli, L. KARWACKI and W. BENNI (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 42 (1906), Nos. 3, pp. 252-254; 4, pp. 345-348).—The agglutinating power of tuberculous sera for tubercle bacilli is much less than in the case of such diseases as typhoid and cholera. In general the absorption coefficient diminishes as the concentration of the serum increases. The agglutinins were apparently destroyed by heating the serum to a temperature of 100° C. diluted in 3 parts of water to which 3 per cent of glycerin had been added.

Abdominal zooglic tuberculosis of birds, J. ROGER (*Rev. Vét. [Toulouse]*, 31 (1906), No. 12, pp. 761, 762).—Quite frequently, supposed cases of tuberculosis of the internal organs of fowls prove to be due to mites or some other organism than the tubercle bacillus. In most cases of true tuberculosis of fowls, the spleen is affected and the liver is almost invariably attacked.

Experiments with fish tubercle bacilli cultivated at a temperature of 37° C., A. AUJESZKY (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 42 (1906), No. 5, pp. 397-401).—Considerable difficulty has been experienced in getting tubercle bacilli from fish to live at a blood temperature. The author began with a medium containing potatoes and glycerin water at a temperature of 28 to 30° C. and after 6 weeks, or at the end of the fifth generation, the temperature was increased to 37° C. In the meantime the cultures had ceased to be white and glistening, as is the case with ordinary tubercle bacilli from fish, and had assumed a yellowish-gray color resembling that of the ordinary mammalian tubercle bacilli.

These bacilli after cultivation on the media maintained at a temperature of

37° C. were pathogenic for guinea pigs, producing death within 38 to 63 days. Three calves were inoculated with the same material and 2 remained healthy while the third developed a local tuberculous infection.

Chronic pseudotuberculous enteritis in cattle, B. BANG (*Berlin, Tierärztl. Wchuschr.*, 1906, No. 42, pp. 759-763).—Considerable controversy has prevailed regarding the exact nature of tuberculous enteritis in cattle. It appears that the author has demonstrated its infectious nature and that it is often associated with cases of true tuberculosis affecting other organs of the body. Positive results were obtained in a number of cases by feeding portions of the mucous membrane of the intestines from animals affected with the disease. The symptoms produced in this way were identical with those which appear in spontaneous cases.

Anthrax, PROFÉ (*Fortschr. Vet. Hyg.*, 4 (1906), No. 7, pp. 145-149).—The author presents a report of a conference of official veterinarians regarding the effectiveness of the laws of Prussia relating to the control of anthrax. It is recommended that the compulsory notification provision be extended to all cases in which the symptoms resemble those of anthrax. This notification should be made immediately to the police authorities and the local official veterinarian should have authority to determine the method of procedure in the case.

The spread of anthrax in animals and man, J. DUNSTAN (*Vet. Rec.*, 19 (1906), No. 954, pp. 236-238).—Attention is called to the statement that anthrax appears to be on the increase during recent years. The reliability of statistics on the spread of anthrax is questioned on account of the fact that local authorities are often unwilling to report cases and incur the expense of disposing of carcasses. The symptoms of the disease are described and facts are presented relative to the intertransmission of the disease between man and animals.

The inoculability of anthrax, E. LECLAINCHE (*Rev. Gén. Méd. Vét.*, 8 (1906), No. 94, pp. 539-544).—A historical account is presented of some of the early experiments which showed that anthrax could be transmitted by inoculating healthy animals with infected blood.

The action of anthrax serum, E. GOTTSTEIN (*Hyg. Rundschau*, 16 (1906), No. 29, pp. 1113-1120).—An enormous variation in the agglutinating power of different sera for anthrax bacilli has been noted by different investigators. In some cases it is claimed that agglutination took place in dilutions at the rate of 1:500,000. The author, however, was unable to get any positive results or to demonstrate any difference in the action of normal and immune serum upon anthrax bacilli.

East coast fever, S. B. WOOLLATT (*Natal Dept. Agr. Bul.*, 11, pp. 14).—The author presents in a condensed form the most important points which have been demonstrated regarding the nature, occurrence, and treatment of this disease. It is believed that one of the chief agencies in spreading the disease is to be found in the oxen used for draft purposes and driven about the country from place to place.

Cattle tick eradication in northwest Arkansas, W. G. VINCENHILLER (*Arkansas Sta. Bul.*, 93, pp. 17-29, figs. 3).—During 1906, a preliminary survey of northwest Arkansas was made by the officials of the experiment station and the Bureau of Animal Industry for the purpose of determining the extent of infestation with cattle ticks. In Benton County 7,474 cattle were inspected, of which 481 were found to be infested, while in Washington County 903 cattle were infested out of 2,003 inspected.

The slight infestation of cattle as observed in the Texas-fever regions of Arkansas indicate that the eradication of the ticks and the control of Texas

fever would be a comparatively easy problem in that State. Infestation of cattle with ticks persists by reason of driving herds in from Indian Territory and from the lack of control of cattle on the public range.

Progress made in exterminating the cattle fever tick in North Carolina. T. BUTLER (*Raleigh: N. C. Dept. Agr.* [1907], pp. 5, figs. 3).—The author calls attention to the progress which has been made since 1902 in exterminating cattle ticks in North Carolina.

During the past 5 years 20 counties of the State have been freed from ticks and this is held as indicating what can be accomplished in all sections where stock laws prevail. The price paid for cattle below the quarantine line is from $\frac{1}{4}$ to $\frac{1}{2}$ ct. per pound less than for cattle of the same quality above the line and this alone would mean a loss of \$50,000 annually in the area which has been freed from ticks. This amount is about three times the total cost of the work of eradicating ticks in these counties during the entire 5 years. For the most part the ticks have been eradicated by the use of the starvation method.

Malignant catarrhal fever of cattle. E. DIEM (*Wechschr. Tierheilk. u. Viehzucht*, 50 (1906), No. 42, pp. 826, 827).—This disease has been almost unknown in the region of Burghausen for the past nine years, but occurred to a limited extent during the present season. The author treated 3 animals by injecting 1.5 liters of physiological salt solution subcutaneously for 3 days in succession. The treatment was without result. In this case it was believed that infection came through the ground water, and a suitable system of drainage was, therefore, recommended.

An unusual case of chronic tympanites in cattle. H. HOLTERBACH (*Berlin. Tierärztl. Wechschr.*, 1906, No. 37, pp. 679-681).—The usual symptoms of tympanites are described with particular reference to a chronic case which came under the author's observation. In this case the abdomen of the cow became considerably distended with gas after each feed. Remedial treatment was of no avail and the animal was slaughtered. An examination of the intestines showed that the duodenum was firmly attached to the liver, at which point the lumen was very small. The intestine also made a sharp turn almost at right angles at about the same level.

Pathogenesis and treatment of railroad disease of cattle. J. SCHMIDT (*Berlin. Tierärztl. Wechschr.*, 1906, No. 43, pp. 775-779).—According to the observations reported in this article, railroad disease attacks chiefly pregnant cows which have been maintained on pastures until the time of shipment. The symptoms include fever, loss of appetite, and cerebral anemia.

The author concludes that railroad disease of cattle should be described as an anemia of the cerebral nervous system and disturbances of the vasomotor nerves as a result of transportation in cars. No suitable preventive treatment has been devised, but cases which have developed may be treated with much success by pumping air into the udder in the same manner as recommended for treatment of milk fever.

An investigation in the County of Wexford of a disease in young cattle. J. H. NORRIS (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 7 (1906), No. 1, pp. 17-25, pls. 8).—Earlier investigations along this same line have already been noted (E. S. R., 16, p. 1027). The author has confirmed his previous view that the presence of *Strongylus gracilis* in the stomach of young cattle may cause a serious wasting disease and death if no attention is given to the animals.

Medical treatment of the disease appears to be of little value, but the trouble may best be prevented by providing small clean pastures, in which the calves may be maintained for the first year.

Diseases of the stomach in cattle. A. EBER (*Ztschr. Tiermed.*, 10 (1906), Nos. 5, pp. 321-355; 6, pp. 401-427).—The author presents in a succinct form a

monographic account of the various diseases which may affect the stomachs of cattle.

Gid of cattle, E. DIEM (*Wehnschr. Tierheilk. u. Viehzucht*, 50 (1906), Nos. 45, pp. 881-887; 46, pp. 903-906).—The symptoms of gid in cattle are described with particular reference to its early diagnosis and operation. The author maintains that in nearly all cases where the value of the animal is considerable it is well worth while to remove the bladder worm from the surface of the brain, especially since the operation is comparatively simple and the animal recovers within a few days.

Milk fever and treatment with air infiltration, ALBRECHT (*Wehnschr. Tierheilk. u. Viehzucht*, 50 (1906), No. 38, pp. 741-747).—The literature relating to this disease was briefly reviewed with particular reference to the condition of the udder observed in cases of milk fever. In a case reported at some length by the author the udder remained unusually flabby during the last 3 weeks before parturition and was not greatly distended after parturition. The symptoms of milk fever which developed were relieved by the infiltration of air and a prompt recovery took place.

Cystitis and its treatment, GMEINER (*Monatsh. Prakt. Tierheilk.*, 18 (1906), No. 1-2, pp. 61-79).—The usual forms of cystitis in domestic animals are described and clinical notes are given on a number of cases.

During the author's experiments with remedies it was found that mercuric oxycyanid in the proportion of 1:5,000 to 10,000 in water, with the addition of salt, constitutes the most satisfactory antiseptic for relieving the inflammatory conditions and bringing about a cure of all ordinary cases of cystitis. Among the medicines suitable for internal use the best results were obtained from urotropin in doses of $\frac{1}{2}$ to 1 gm. three times daily for small animals and 5 to 10 gm. for larger animals. Both of these lines of treatment may be combined with excellent results.

Septicemia of swine, J. PEKAR (*Tierärztl. Zentbl.*, 29 (1906), No. 31, pp. 489-491).—The controversy regarding the development of septicemia or swine erysipelas as a result of vaccination for the latter disease makes it necessary to examine carefully into the cause of death in cases where claims for indemnity are made. In most cases claimed to be swine erysipelas as a result of vaccination, the disease was believed by the author to be septicemia and disinfection measures are recommended for preventing this trouble.

Lesions of chronic swine erysipelas, S. EISENMANN (*Jour. Méd. Vét. et Zootech.*, 57 (1906), pp. 530-538, 577-588, figs. 5).—Brief descriptions are furnished of the lesions which arise in chronic cases of swine erysipelas in the joints, liver, stomach, intestines, and skin. The great differences observed in the effectiveness of vaccination in different hogs are ascribed to variations in the strength of the vaccine used, the extreme susceptibility of some hogs to the disease, and variations in the length of time during which the vaccinated hogs are kept under observation.

Pathological changes in the crystallin lens in various forms of cataract in horses, F. METTE (*Monatsh. Prakt. Tierheilk.*, 18 (1906), No. 3-4, pp. 97-133, pls. 4).—The literature relating to cataracts in horses is carefully reviewed in connection with a short bibliography.

The histological pathology of different forms of cataracts is described in detail. It appears that in general the anatomical changes cause a cloudiness of the capsule of the lens, the substance of the lens, or both. The pathological changes may consist in a deposition of coloring matter in the interior part of the capsule, in the formation of fibrous tissue on the inner surface of the capsule, or in the proliferation of the epithelium of the inner surface of the lens.

Recurrent mange in horses, T. B. GOODALL (*Vet. Rec.*, 19 (1906), No. 955, pp. 251, 252).—The author has noted a number of cases of this disease in which the symptoms were quiescent during the cold months but reappeared in the spring and summer for 3 years in succession. It has been observed that chicken mites will live for a year or more in close confinement without any food being given them. In such cases the mites found alive at the end of the period must have maintained themselves by cannibalism. The same may be true for the mites of horse mange.

Horse sickness, L. E. W. BEVAN (*Rhodesian Agr. Jour.*, 4 (1906), No. 1, pp. 46-51, pl. 1).—The symptoms of this disease are described in detail. A system of vaccination has been devised which protects horses quite successfully. On an average somewhat less than 4 per cent of vaccinated animals die. There is little hope of good results from the use of any medicinal treatment of horse sickness.

The distribution of equine piroplasmosis in Italy, L. BARUCHELLO and A. PRICOLO (*Clin. Vet. [Milan]*, 29 (1906), No. 42, pp. 1009-1015).—This disease, which also passes under the name of typhoid fever or typhoid influenza, occurs quite generally throughout Italy. Notes are given on the symptoms and pathological processes which accompany the disease.

The use of mercury in the treatment of equine piroplasmosis, G. BARONI (*Clin. Vet. [Milan]*, 29 (1906), Nos. 43, pp. 1033-1046; 44, pp. 1057-1066).—Repeated experiments were made in testing bichlorid and biniodid of mercury in intravenous inoculation for the treatment of equine piroplasmosis. The results obtained were quite promising, but the author does not feel justified in recommending this treatment as certain to give desirable results.

Piroplasmosis in dogs, J. WETZL (*Ztschr. Tiermed.*, 10 (1906), No. 5, pp. 369-379, figs. 3).—*Piroplasma canis*, which has frequently been demonstrated in dogs, closely resembles the blood parasite of Texas fever in cattle. The morphology and biology of this parasite is described and notes are given on symptoms in cases of piroplasmosis in dogs. Inoculation of healthy dogs with the blood of affected animals readily produces infection.

Rabies and the capture of stray dogs, H. MARTEL (*Rev. Vét. [Toulouse]*, 31 (1906), No. 11, pp. 710-720).—Statistical data are presented regarding the extent of rabies in parts of France as related to the number of stray dogs. The results of an organized crusade against stray dogs are very striking. Since 1885 the total number of dogs in Paris has greatly increased, while the percentage of rabies among dogs has fallen rapidly. The author argues, therefore, for the great advantage of the destruction of all stray dogs.

Rabies in rats and field mice, B. GALLI-VALERIO (*Ccuttbl. Bakt. [etc.]*, 1. Abt., Orig., 42 (1906), Nos. 3, pp. 203-208; 4, pp. 297-303, fig. 1).—In a study of rabies in rats and field mice it appears that Negri's bodies are exceedingly rare and small as compared with the same structures in dogs and most other animals susceptible to rabies. The attenuated virus obtained from the medulla oblongata of infected rats and mice did not always have the power of protecting other rats and mice against the disease.

Nagana in poultry, O. GOEBEL (*Compt. Rend. Soc. Biol. [Paris]*, 61 (1906), No. 30, pp. 321-323).—Poultry are considered by most investigators to be immune to nagana. The author found, however, that fowls inoculated with nagana virus obtained from guinea pigs retained the virulent blood in the body for a period of nearly 2 months. When removed the virus was found to have retained its virulence and to be fatal for guinea pigs.

Filaria clava in the domestic pigeon, L. G. NEUMANN (*Rev. Vét. [Toulouse]*, 31 (1906), No. 10, pp. 661-664, figs. 2).—This parasitic worm was first described

as occurring in pigeons in 1856. The author has made a study of the anatomy and biology of the pest, which are described in the present article. The parasite is found most commonly in the connective or subcutaneous tissue about the trachea and elsewhere in the region of the neck.

RURAL ENGINEERING.

Can the yield of crops be increased by irrigation under the climatic conditions of Germany? GERLACH (*Mitt. Deut. Landw. Gesell.*, 21 (1906), No. 49, pp. 384-386).—The writer takes up this question in a general way, giving some results already found and suggesting lines along which research should continue to determine if irrigation is practicable and profitable in Germany. German experiments are quoted which give the absolute water requirements of different crops per pound of dry substance, as follows: Wheat, 338 lbs. of water; rye, 353 lbs.; oats, 376 lbs.; barley, 310 lbs.; peas, 273 lbs.; red clover, 310 lbs.

From experiments with and without fertilizers, it is concluded that irrigation is of little value in increasing the yield when there is a deficiency in plant-food material. Thus, without fertilizers, 1,665 lbs. and 3,330 lbs. of water resulted in an increase in yield of 1.48 lbs. and 1.59 lbs. of dry substance, respectively; and with fertilizers, 2.89 lbs. and 7.9 lbs., respectively.

The rainfall necessary to produce a normal development of field crops in Germany is given as follows: Winter grain, 23.6 in. per year; barley, 20.8 in. per year; oats, 25.2 in. per year; potatoes and beets, 23.6 in. per year.

A table is also given showing the ideal distribution of rainfall through the year by months. The results are not applicable for all parts of Germany, since for Pentkowo in 1903-4 the following crops were grown with only 15.65 in. of rainfall: Rye, 3,740 lbs. per acre; wheat, 4,460 lbs. per acre; oats, 3,740 lbs. per acre.

With regard to the most successful way of retaining soil moisture, the author states that it is doubtful if much can be added to the present knowledge of the effects of cultivation and tillage. He thinks, however, that in case of drained lands the common German practice is to drain too thoroughly, particularly in spring and summer, in localities having but little precipitation during these seasons.

On automatic puddling of channels, [H. MARSH] (*[Proc.] Irrig. Conf., Simla, 1904, 1, pp. 130-133, figs. 4*).—The necessity is stated of providing some means of lessening the 50 to 60 per cent loss in water between the canal head and the fields. Lining the channels by manual labor is not considered practicable, since it is estimated that the lining of a 3-ft. lateral would cost about \$2,500 per mile and would lead to a return of only \$75 per mile. In the writer's opinion the only practicable method is the puddling of the perimeter of the channel by the running water. This he effects by giving the main canals a slope of about 0.5 or 0.6 ft. per mile. Deposition of silt in distributaries is said to be due more to excessive erosion in the main canals than lack of velocity in the distributaries.

Instances of the success attendant upon reduction of canal slope are given. In one case on the Ganges canal the breaking up of a rapid slope probably is responsible for a saving of 19 cu. ft. per second out of a total of 42 cu. ft., the net outcome being that an expense of about \$10,500 produced a capitalized economy of water amounting to \$190,000. In another instance a channel with a gravelly bed experienced a loss of 27 per cent in the discharge when water was first turned in. The percolation thereafter diminished to 1.8 per cent, due to gradual silting up.

The artesian wells of Australia, P. PRIVAT-DESCHANEL (*Génie Civil*, 49 (1906), No. 20, pp. 309-312, figs. 5).—A study of the peculiar conditions which in Australia have favored the extensive use of artesian wells. Sections are given showing the geological formation, which is a typical half basin, with the infiltration zone on the west slope of the dividing range on the east coast, and with a continuous flow toward the Gulf of Carpentaria. At the present time Queensland possesses 960 wells, public and private, of which 628 are flowing. Their total depth is 357 km., and total daily flow is 1,750,192 cubic meters. In New South Wales the total daily discharge is 631,744 cubic meters. With those of Queensland, they furnish the enormous total of 2,381,936 cubic meters per day.

The legislation on the subject is unique. The government upon petition and after investigation of the practicability of the scheme will drill wells in any locality, the expenses being met by special tax upon the proprietors benefited. The tools, superintendence, and transportation of supplies are furnished by the government. Although the latter exercises no supervision over private wells, a special system has been devised whereby the State leases very large tracts at a modest rental, \$4 to \$10 per hectare, for a period of 24 years, with privilege of indefinite renewal, upon condition that the lessee bore artesian wells, from which he is to profit during the term of lease but which become the property of the State after abandonment.

Artesian water is applied in Australia to three purposes, briefly: (1) The establishment of public watering places on the long overland trails; (2) cultivation by irrigation, patterned after California methods, fruit being extensively grown on blocks of 15 to 20 acres surrounding artesian wells and to which the government rents a certain quantity of water at a profitable price; and (3) stock raising.

In spite of the number of wells the level is not appreciably lowered, even in periods of exceptional drouth, and the prospects of this water supply when so developed as to make possible the settlement of central Australia are considered very good.

The wind engine for pumping, G. PHELPS (*Surveyor*, 30 (1906), No. 779, pp. 702, 703).—In a paper read before the Association of Water Engineers in London the writer discusses the modern windmill in connection with its use in the pumping of water for the supply of small rural communities.

The cost of oil and attendance for such mills is figured at from \$25 to \$30 per year, but it is considered necessary, in order to secure a constant supply, that reservoir capacity be provided, as well as auxiliary machinery, which in some cases may be a horse gear arranged to be coupled to the pump during long-continued periods of calm. A table is given showing an approximate average duty of wind-pumping engines, with an assumed lift of 100 ft., including friction, from which the following figures are taken:

Average duty of wind-pumping engines.

Diameter of wheel in feet.	Revolutions of wheel per minute in a 15-mile wind.	Water raised per day in gallons, 100-foot lift.
10	18	1,200
12	40	2,000
14	34	3,500
16	30	6,500
20	24	16,000
40	12	80,000

These figures are given as the result of actual experience and in the opinion of the writer may be relied upon, assuming the site to be reasonably good and

the pump proportioned to the work. The calculations for total quantities raised are based on an assumed average of at least 8 hours per day, with a wind sufficiently strong to work the mill at average speed, which in practice is found to be a safe assumption.

With regard to wind velocity it is stated that intermittent working only can be expected with velocities of 5 to 10 miles per hour. With velocities of 10 to 15 miles per hour steady working at about average speed should be obtained.

A typical example of a village supply pumped by wind power is given, from which the following particulars are abstracted: Wind wheel 18 ft. diameter, with hinged canvas sails, working a single-acting, deep-well pump $4\frac{1}{2}$ in. diameter and 8-in. stroke, well 55 ft. deep; total lift from water level to reservoir 130 ft., exclusive of friction. Reservoir capacity 30,000 gal., equivalent to 6 days' supply for a population of 400 people. Auxiliary machinery consists of a triplex pump, worked by horsepower. The cost of pumping was found to be less than \$15 per annum. Cost of windmill, horse gear, pumps, and well fittings, \$1,725, and total cost of whole scheme, \$11,000; cost of attendance, \$25 per annum.

The trials of suction gas plants at Derby, 1906 (*Engineer (London)*, 102 (1906), Nos. 2659, pp. 608-611; 2660, pp. 625, 626).—The Royal Agricultural Society conducted a number of tests of suction gas plants in June, 1906, at the annual show at Derby, England. The declared object of these tests was to determine as well as possible in the short time allowed whether suction gas plants would work as reliably under agricultural conditions as the steam engine and with as small an amount of attendance as the oil engine. A satisfactory answer to these questions would prove the suitability of such plants for agricultural purposes, since their advantages from the standpoint of economy are accepted without question. The deciding factor in judging the merits of the different plants tested was their simplicity, since it was expected that the plants in many cases would be placed in charge of farm hands who would be unable to make adjustments which lead to small economies in working.

The regulations surrounding the tests were fairly stringent, it being intended to duplicate, as nearly as possible, the running conditions of actual practice. The plants tested were limited to sizes ranging at and below 20 horsepower, and a variation of not more than 5 per cent from the declared horsepower was allowed. The engines were run for 9 consecutive hours under constant load, when they were shut down for the night, to resume running next day. Special attention was paid to the following points: (1) Attendance necessary; (2) general design, including facility of cleaning and space occupied; (3) regularity of work; (4) fuel consumption and water consumption; (5) price; (6) relative proportions of gas producer and engine; (7) volume swept by piston relative to brake horsepower.

The results of observations upon several of these points are briefly given, as follows:

1. It was found that, without considering the additional help in turning over the engine at starting, one attendant only was required, and his time could largely be spent in other duties. Although less manual labor is required than in the case of the steam engine very intelligent care is necessary, however, to produce gas of good quality.

3. Although regularity of working, so far as the engine was concerned, was found to be dependent upon the amount of tar present in the gas, the gas producer itself is evidently the portion of the plant requiring most attention, since the gas is made as required and consequently difficulty is experienced in responding quickly to changes from light to full load.

4. In testing the fuel consumption the fact was kept in mind that it is important to know not only the amount consumed during the run, but also the amount consumed during the night when the fire was banked. It was concluded that where coke could be obtained it would be a more desirable fuel than anthracite coal, even when not considering the greater tendency of the latter to produce tar. In the 11 plants tested the consumption per brake horsepower at full load varied between 1.04 and 1.48 lbs.; at half load between 1.38 and 1.98 lbs.; and at full load with coke between 1.21 and 1.65 lbs., while the difference between the best and the worst plants at full load was less than $\frac{1}{2}$ lb. of coal. The difference among the better plants was almost insignificant, amounting to no more than 0.04 lb. Questions of economy can, therefore, be left out of account in deciding upon the make of plant to use, the decisive factor being cost per brake horsepower. This varied in the tests given between \$44 and \$85, the winners of the awards both pricing their plants at about \$56 per brake horsepower.

An interesting fact developed at the trials was that as much water was required for the operation of these plants as would be necessary for a steam engine plant. Various tables are presented, giving details of the test, such as compression, explosion, and suction pressures, and other data, making the report one of unusual interest and value.

Additional information on the durability of wooden stave pipe, A. L. ADAMS (*Engin. News*, 56 (1906), No. 15, p. 378, fig. 1).—A wooden stave pipe at Astoria, which is buried in the earth and is under constant water pressure, has proven deficient in durability, contrary to preconceived ideas as to the behavior of wood under such conditions. The pipe in question deteriorated so much in ten years that extensive renewals and repairs became necessary during 1905. The facts made prominent from the experience with this pipe are as follows:

" (1) Staves, which are constantly subject to water pressure from within and are buried in the ground, may be very short-lived.

" (2) The magnitude of the water pressure, beyond a moderate head, has had little or no influence in preserving the timber.

" (3) The pipe laid above ground has not deteriorated to any considerable extent, nor has the pipe laid in the tunnels leading from the distributing reservoir.

" (5) When the depth of backfill has exceeded 2 ft. above the pipe, and the material has been free from vegetable matter, and has been of a fine and impervious character, much less deterioration has taken place.

" (7) Decayed staves have been found all around the pipe.

" (8) Sound staves have been frequently found contiguous to badly decayed staves.

" (10) The bruising of the staves during the process of erection seems to have been one of the chief agencies in hastening decay.

" (11) Decay has been confined to the outside of the pipe.

" (13) The malleable cast band fastenings have been found to be in good condition."

Economics of road construction, H. P. GILLETTE (*New York: The Engineering News Pub. Co., 1906, 2, ed., pp. 39, figs. 9*).—In this work the author undertakes to point out certain defects in current road engineering practice and to correct certain common errors in estimates and specifications. He advises designing the cross section of the road in such a way that modern excavating and grading tools can be used in construction. It is claimed that deep side ditches are unnecessary, since the heaving action of frost is said not to affect materially a macadam road with a foot of dry soil beneath it. In view of the

fact that the tractive power of a team may be as great as 1,000 lbs. for a short time, grades as heavy as 7 per cent are said to be allowable, thus frequently avoiding the necessity of constructing deep cuts.

A new theory is advanced as to the cause of the binding which takes place when a broken stone road is rolled and sprinkled, it being claimed that the surface tension of water in the capillary voids of the screenings is the true binding agent, from which it is argued that there should be considerable fine dust in the binder. Certain economies in the construction of macadam roads are pointed out, and the laws under which roads are built are briefly discussed.

Corn-harvesting machinery, C. J. ZANTHO (U. S. Dept. Agr., Office Expt. Stat., *Bul. 173*, pp. 48, pls. 4, figs. 24).—In this bulletin the author reviews the history of corn-harvesting machinery, tracing the development of the present types of machinery from the earliest inventions and appliances and discussing the various methods of harvesting corn in use at present.

The several machines for cutting and shocking corn are described and data are given as to their draft, cost, and operating expenses. Some of the objections and advantages of the corn pickers which have been invented from time to time are briefly touched upon. Cutting and shredding machines and huskers and shredders are described and their operation from the standpoint of safety of the operator is gone into with some detail. Following this the author takes up the economics of corn-harvesting problem, and gives data on the cost of harvesting by hand and machines, the cost of filling silos, and of shredding and preparing fodder.

In conclusion, the author states that "the best way to preserve the greatest quantity of food materials of the original corn fodder for feeding of farm animals is by means of the corn harvester, ensilage cutter, and the silo. The cost of placing 1 acre of corn in the silo is about the same as that of an acre of cured fodder. . . ."

"By the use of the proper machinery for harvesting the corn crop, the farmer may increase the net income from his crop \$8.72 per acre over hand methods of harvesting the ears and wasting the stalks and still allow full price for the use of the different machines."

Cost notes on a reinforced-concrete silo (*Engin. Rec.*, 54 (1906), No. 22, p. 607, figs. 2).—A cylindrical-shaped silo recently built at McLean, Ill., has the following dimensions: Height, including footing, 28 ft.; inside diameter, 22 ft. 3 in.; thickness of wall, 6 in.; footings extend 2 ft. below ground level and are 9 in. thick; total quantity of concrete 38.2 cu. yds.

The silo was built up by the aid of forms consisting of 2 concentric rows of T-shaped posts held erect by guys, each row supporting two thicknesses of weatherboarding, which in turn formed the backing of the curbing. The latter consisted of 2 in. by 8 in. sticks 4 ft. long, supported vertically and which were removed after the completion of each successive section of the work by loosening the rings from the posts, the rings then being moved up to the next section, the curbing replaced, and more concrete filled in. The work progressed at the rate of 4 ft. vertically per day, the forms being filled in the afternoon and moved up the following forenoon. The work was done by farm laborers hired by the month and required 100 man-days of such labor. A mason spent 7 days at \$3.50 per day brushing and troweling the surface. The concrete used was in the proportion of one of cement to six of sandy gravel, the former costing \$100, the latter \$35. The reinforcing consisted of ten iron hoops ($2\frac{1}{2}$ by $\frac{5}{8}$ in.) equally spaced in the lower half of the structure. In the upper half 1 ring of 4 ft. woven wire fencing was placed in each section. The total cost of reinforcing was \$5.20, which does not include the hoops, or the new lumber

necessary (weatherboards), which cost \$18. With farm labor at \$1.75 per day, the total cost of the silo, not including old material made use of, was \$360 or \$9.42 per cu. yd.

RURAL ECONOMICS.

The relations of rents, wages, and profits in agriculture, and their bearing on rural depopulation, J. S. NICHOLSON (*London: Swan, Sonnenschein & Co., 1906, pp. 176; rev. in Jour. Roy. Statis. Soc., 69 (1906), No. 4, pp. 763-765*).—This is a series of lectures delivered at Cambridge University on the history and economics of agriculture.

The history of agriculture is traced from the mediæval period to the present time, and the economics of agricultural rent, wages, and profits are compared. As a result of these studies the author maintains that modern rents in money terms are not as onerous as when tenant-farmers paid rent in labor and in produce; that a steady augmentation has occurred in the price of farm labor, while otherwise the agricultural industry is depressed; and that there has been no wholesale depopulation of the rural districts of England. "The relative increase of the urban population is shown to be world-wide and due to far-reaching economic causes, and not to any peculiarities of land tenure or systems of cultivation or property."

The return to the land, J. MÉLINE (*London: Chapman & Hall, 1906; rev. in Jour. Roy. Statis. Soc., 69 (1906), No. 4, pp. 765-768*).—This is a description of the relations of industry and agriculture in France, with a plea for the promotion and improvement of agriculture as a relief from the overcrowding of French cities and the internecine struggle of nations for industrial supremacy.

To encourage the repopulation of rural districts, the author suggests among other means greater facilities in securing agricultural credit, a larger extension of cooperative methods, governmental relief from oppressive taxation on agricultural lands, better rural education, the enactment of a homestead law, and other measures.

Report of the Agricultural Organization Society for the 18 months ended June 30, 1906, R. A. YERBURGH and J. N. HARRIS (*Rpt. Agr. Organ. Soc. [London], 1906, pp. 127, figs. 12, map 1*).—This report reviews the progress of the agricultural cooperative movement in England and Wales from its origin in April, 1901, to June, 1906, and gives a review of the work of the Agricultural Organization Society for the 18 months ended June 30, 1906.

The organization had at this latter date 134 affiliated societies in 41 counties, and at the close of the year 1905 reported 7,439 members and a business of £221,524 for that year.

The work of the societies embraces the purchase of agricultural supplies, cooperative ownership of machinery, cooperative sale of produce, experiment plats, improvement of live stock, agricultural credit, motor service, and the regulation of the tenure of allotments and small holdings. Every branch of the work was prosperous and of great advantage to farmers, but the committee believes that "if the A. O. S. had larger funds the development of agricultural cooperation in England and Wales would proceed with far greater rapidity than at present." To overcome this difficulty a central cooperative agricultural bank has recently been organized and registered, the sole purpose of which is to advance money to local credit societies which "will be able to play to the full their function of collecting the savings of country districts and returning them in the form of the much-needed capital for the exploitation of the land."

Agricultural cooperative societies [in Brazil], C. BORGES, Jr. (*Bol. Dir. Agr. Bahia, 8 (1906), No. 5, pp. 460-467*).—The author points out in this article the

advantages that have resulted to farmers in European countries through cooperative and credit societies, shows the difficulties in the way of agricultural organization in Brazil, and urges upon the government the advisability of improving rural educational conditions. The establishment of research stations and cooperative societies he maintains would be of great advantage to the agricultural class and to the economic welfare of the country at large.

The use and objects of agricultural societies, E. B. DENHAM (*Trop. Agr. and Mag. Ceylon Agr. Soc.*, 27 (1906), No. 6, pp. 500-503).—The author discusses the origin, development, and aims of the Ceylon Agricultural Society.

This society was founded in November, 1904, and at the close of 1906 had 1,120 members and 45 branches with a membership of about 3,500. Besides publishing leaflets from time to time on agricultural topics in the Singhalese, Tamil, and English languages, the society has selected the *Tropical Agriculturist* as its official organ. This publication is issued in English and Singhalese, and is sent free to members of the society.

Among the aims of the society are the introduction of new varieties of paddy from India and Japan, the introduction of new products, the encouragement of cotton cultivation, and the distribution of vegetable seeds. "The use of the branch societies as cooperative centers for experiments and for the adoption of the cooperative credit system is another side of the society's work." In general, the main purpose of the society and its branches is to accumulate and disseminate among Singhalese farmers the most advanced and practical information on all phases of agriculture.

The "Dông-Loi" native cooperative societies in Tonkin, C. PRÊTRE (*Bul. Écon. Indo-Chine, n. ser.*, 9 (1906), No. 58, pp. 1025-1057).—This is a report by the civil-service administrator to the governor-general of French Indo-China regarding the progress of the cooperative agricultural societies of Assam during the 4 years of their existence, with suggestions as to the best means of promoting the welfare of the native farmers through cooperative societies.

It is shown that the native farmers have been for years at the mercy of unscrupulous money lenders, who charge high rates of interest, and the societies were organized for the purpose of enabling the members to buy seed rice and other agricultural necessities at reasonable rates and to sell their products at better advantage. For the future development of these societies it is recommended that the government encourage the establishment of district cooperative banks, as has been done in France, for the purpose of accumulating the savings of the peasants and of purchasing and supplying seed rice to the members at an amount equal to the value of their deposits, and also for the establishment of a rice granary under government control to provide seed and food to the natives at reasonable prices in times of scarcity or famine.

A series of appendixes give the by-laws of representative societies, a statement of accounts showing their financial condition on December 31, 1905, and a table showing the quantity and value of paddy sold to the society by producers in the province of Kiên-an in 1905 and 1906.

Crop Reporter (*U. S. Dept. Agr., Bur. Statist. Crop Reporter*, 9 (1907), Nos. 1, pp. 1-8; 2, pp. 9-16).—These numbers for January and February, 1907, contain, in addition to the usual statistics on the yields and condition of crops in the United States and foreign countries, special articles on: Tobacco crop by types—average price; exports of wheat, July to November, 1906; stocks of American cheese, December 31; high price of India jute; number and value of farm animals, January 1, 1907; colonial cotton production; the 1906-7 wheat and flaxseed crops of Argentina; foreign trade in farm and forest products, 1905 and 1906; and other agricultural topics.

Comparison of English and foreign agriculture (*Jour. Roy. Statis. Soc.*, 69 (1906), No. 4, pp. 746-751).—In this article attention is called to certain leading contrasts in the agriculture of typical European countries.

Statistics are presented and discussed which show the acreage in cereals, potatoes, root crops, and fallow per 1,000 acres in 8 countries of Europe, and a comparison is drawn between the agricultural position of Germany and Great Britain. From statistics on the wheat areas, it would seem that there are 110,000,000 acres of this cereal under cultivation in Europe, "of which much more than half is to be found in Russia, Hungary, and the Danubian states." Russia, Poland, and Germany together have 83 per cent of the rye crop.

Data are also compared as to the number of cattle and sheep in 13 European countries. Belgium leads in the number of cattle and the United Kingdom in sheep, with 245 and 374 per 1,000 acres of land, respectively.

Agricultural statistics and chattel mortgages, N. MONTEITH (*Ann. Rpt. Bur. Indus. Ontario, 1905*, pp. 48).—In addition to meteorological phenomena for 1905, this report gives in part 1 detailed statistical data of the acreage, yields, and market value of the staple field crops grown in each county of Ontario in 1905, together with the totals for the province for the past 10 years and the average for the 14 years 1892-1905.

From bulletins issued by the Ontario department of agriculture abstracts are given on the season and crops for the year, live stock and dairying, labor and wages, etc. A scarcity of farm labor prevails, notwithstanding the presence of fresh immigrants from Great Britain. "Farmers are utilizing improved machinery and newer methods more and more in order to get along with less manual aid. Skilled farm laborers receive from \$30 to \$40 a month, and from \$1.50 to \$2 a day, during harvesting, but inexperienced men get as low as half these wages."

Part 2 consists of tabulated data regarding chattel mortgages in the province for the years 1896 to 1905, inclusive. The prosperity of the farmers in the province is shown by the reduction of the number of mortgages from 11,638 in 1896 to 7,403 in 1905, securing indebtedness of \$3,826,582 and \$2,758,046, respectively.

Agricultural statistics of Ireland, with detailed report for the year 1905 (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statis, 1905*, pp. 166).—This report contains statistics on the acreage under crops, crop production, number of land holdings in each county and province, live stock, dairy industry, bee keeping, milling industry, forestry, wages of laborers, and other matters relating to agriculture in Ireland.

Agricultural statistics, Ireland, 1906 (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statis, 1906*, pp. 23).—Data are presented regarding the acreage under crops and the number and kind of live stock in each county and province of Ireland for the years 1905 and 1906.

Agricultural statistics of India for the years 1900-1901 to 1904-5 (*Agr. Statis. India, 21 (1904-5), I, pp. 420; II, pp. 90*).—This publication gives detailed data of British India and native States relating to area of all provinces, forest lands, and cultivable and uncultivable lands; crops irrigated and sources and extent of water used in irrigation; area under crops and yields of crops; number of live stock and implements; land revenue of the provinces; transfers of lands; tea and coffee production; and other agricultural statistics.

The basis of rural industry and bookkeeping, J. B. LAMBL, trans. by G. EDANGE (*La Substance de la Propriété Rurale et la Comptabilité Agricole, Paris: Librairie des Sciences Agricoles, 1906*, pp. 32).—The author points out in this pamphlet that the constituents of air and soil, which largely enter into the composition of plants and animals, are to a great extent gratuitously supplied

by nature, and that on this account the cost of production of agricultural products can not be definitely determined. He maintains, therefore, that the double-entry system of bookkeeping employed in industrial pursuits, where all economic factors which enter into the cost of manufactured articles are definitely known, is not suitable for keeping agricultural accounts.

Bookkeeping for farmers, T. C. ATKESON, edited by H. MYRICK (*New York: Orange Judd Co., 1905, pp. 30*).—In this volume a comprehensive system of keeping accounts by Professor Atkeson is supplemented by a practical outline of the Stockbridge system. The two methods are believed to offer to the farmer a system of bookkeeping that will enable him to know at any time "how the business of the whole farm, or any part of it, stands."

AGRICULTURAL EDUCATION.

The education of the farmer, D. KINLEY (*Ill. Agr., 11 (1906), No. 3, pp. 61-66*).—In this paper the dean of the graduate school of the University of Illinois discusses the education of the farmer from the three considerations of success, happiness, and highest social service. In order to be successful it is important that he shall be trained along the technical lines now receiving attention in the agricultural colleges and also in the commercial side of farming—the education which treats of farming as a business and is concerned with the principles of prices, market organizations, transportation routes and rates, competitive sources of supply, farm organization, and similar subjects. To this end he should study among other things economics and industrial history.

The farmer should also be taught the cultural studies—history, literature, language, mathematics, and the like "for the training and the pleasure and the recreation that they bring," and he should be educated for citizenship in order to have an intelligent comprehension of matters of public policy, such as the tariff, the trusts, railroad rates, and the banking problem. Knowledge and right thinking along these lines come largely with the study of history, home economics, and political economy.

The writer recognizes the possibility of educating away from the farm, but thinks that this will be only a temporary effect, that gradually, as more educated men take up farming and social life in the country becomes more agreeable to educated men, there will be less tendency to leave the country on account of the intellectual and social attractions of the city.

The education of the farm boy, G. L. BISHOP (*Bien. Rpt. Okla. Bd. Agr., 2 (1905-6), pp. 285-290, fig. 1*).—An argument for an agricultural education for all farm boys, in which the ways of getting such an education are pointed out and attention is called to its advantages.

Agriculture in public schools, A. M. SOULE (*V. P. J. Agr. Jour., 1 (1906), No. 1, pp. 17-19*).—A plea for nature study in the smaller public schools, agricultural subjects in consolidated rural schools, and regular courses in elementary agriculture and the sciences pertaining thereto in all high schools. The writer considers that the main difficulty in carrying out such a program is not inability on the part of teachers to teach agriculture, but indifference toward the subject. He favors the development of suitable courses in agriculture in the secondary schools of the State rather than the establishment of separate agricultural schools.

Agricultural education, A. C. SCOTT (*Bien. Rpt. Okla. Bd. Agr., 2 (1905-6), pp. 261-271*).—An address before the Oklahoma Board of Agriculture comprising a discussion of (1) the education of the man who stays on the farm—elementary agriculture in all public schools, college short courses, the agricultural papers, experiment station bulletins and other literature, and (2) "the

education he could aspire to as a man and a citizen"—the full college course with not only the technical training it implies, but also the culture and refinement that comes from higher training in history, literature, and other subjects of study.

Agriculture in the public schools of Oklahoma, E. E. BALCOMB (*Bien. Rpt. Okla. Bd. Agr., 2 (1905-6), pp. 276-279*).—An address before the Oklahoma Board of Agriculture in which the speaker argued for agriculture in all public schools, not to teach the science or the art of agriculture, but the underlying principles of plant and animal breeding, cultivation of crops, selection of seed, etc., by means of the text-book and practical experiments.

How agriculture is taught in the schools of other lands, and how it may best be introduced into the schools of Texas, A. C. ELLIS (*Texas School Jour., 24 (1906), No. 3, pp. 24-33*).—This is an address delivered October 20, 1906, before the Texas Industrial Educational Convention by the Associate Professor of Education in the University of Texas.

Agricultural education is defined and a course based on the syllabus given in Circular 60 of this Office is outlined and amplified. It is shown that there is a very definite and useful body of knowledge concerning some of the important phases of agriculture, that this can be taught in public schools, and that it ought to be taught not only because of the information given, but also on account of the training given to the mind and body of the pupils.

As regards the programme with reference to this work in Texas schools, it is argued that it would be inadvisable to require the teaching of agriculture in all the one-teacher rural schools. Instead of this it is recommended that (1) all teachers be required to learn something about scientific agriculture and how it is taught, and that the capable and fortunately located teachers be definitely encouraged to introduce agriculture into their schools; (2) the teaching of agriculture be required in rural schools possessing more than one teacher, of which there are about 2,000 in the State, and (3) the 1,000 independent districts in the State be encouraged to introduce agriculture. For the 8,000 one-teacher rural schools in Texas consolidation and more efficient superintendence are recommended.

In order to procure teachers for the work suggested, it is recommended (1) that for the teachers of agriculture in high schools and for the directors and general leaders of this work, the agricultural and mechanical college employ a professor of pedagogy, introduce training courses, and be allowed to grant State life certificates. It is stated that the State university has not the equipment for training these leaders and the normal schools are not doing work of high enough grade. Furthermore, the university and the three normal schools are unable with their present facilities to train all of the teachers needed for the public schools. (2) "For the training of teachers in elementary agriculture there should be established at once short winter and short summer courses especially arranged for teachers." It is thought that in one short session of two months a teacher can get a fair knowledge of what is taught in elementary agriculture, and in two such sessions, with a year of reading and of practice in the school intervening, he may become a really good teacher of the elements of agriculture, such work as is possible in the elementary rural schools having more than one teacher. Such short courses could be given not only at the agricultural and mechanical college, but also at the college of industrial arts, the three normal schools, and, if necessary, at the State university summer school.

Professor Ellis does not believe in the establishment of special high schools to provide secondary instruction in agriculture. He believes such schools have a tendency to create class distinctions, and cites in evidence of this the schools of

Germany and Japan. A large part of a child's education comes from his association with his school companions and with his teachers out of class, and the election of special courses in agriculture is sufficiently narrowing without putting the boy "off in a school in which all the pupils and all the teachers are studying exactly the same subject." In his opinion it would be wiser and more economical to develop a system of agricultural education within the present common school system in harmony with the social organization and social ideals of these schools. He would therefore introduce elective courses in agriculture in the existing high schools of Texas, and provide extra teachers and extra laboratory facilities for this work.

Why agriculture should be taught in the high school, K. L. HATCH (*Wis. Jour. Ed.*, 39 (1907), No. 2, pp. 73, 74).—The reasons given by the author are to prepare students to teach the subjects in the common schools, to prepare students for the work of the agricultural college, and to direct attention to life on the farm and its ever increasing possibilities.

Report of committee on extension work (*U. S. Dept. Agr., Office Expt. Stas. Circ.* 72, pp. 8).—This is the first report of the committee on extension work of the Association of American Agricultural Colleges and Experiment Stations. It includes a definition of extension teaching in agriculture as interpreted by the committee, and a grouping of the divisions of this work as follows: (A) Farmers' institutes, (B) itinerant lectures other than farmers' institutes, (C) literature, (D) object lessons or outdoor practicums, (E) rural societies, and (F) other associations. The report also outlines 42 lines of extension work, and makes a number of recommendations with reference to the future work of the committee.

History of farmers' institutes in the United States, J. HAMILTON (*U. S. Dept. Agr., Office Expt. Stas. Bul.* 174, pp. 96).—This bulletin brings together data respecting the origin and progress of the farmers' institute movement in the several States and Territories up to the year 1904, since which time the progress of the institutes has been recorded in the annual reports of the Farmers' Institute Specialist of this Department. It contains historical data concerning Government aid to institutes, the American Association of Farmers' Institute Workers, and institutes in the several States and Territories, the latter prepared largely by the different State directors of farmers' institutes.

Farmers' institutes (*Ohio Sta. Circ.* 62, pp. 4).—A list of officers of the station and the subjects they are prepared to discuss at farmers' institutes.

MISCELLANEOUS.

Report of the Secretary of Agriculture, 1906, JAMES WILSON (*U. S. Dept. Agr., Rpt.* 83, pp. 94).—A general review of the work of the Department of Agriculture during the fiscal year ended June 30, 1906.

Annual Report of Florida Station, 1906 (*Florida Sta. Rpt.* 1906, pp. LXIV).—This includes the organization list of the station, a financial statement for the fiscal year ended June 30, 1906, a general review of the work of the station during the year, statements concerning cooperative work undertaken, reports of different members of the station staff including in some instances the results of observations and experiments, a list of periodicals received by the station, a subject list of station publications, and an article on pineapple culture abstracted elsewhere.

Report of the Experiment Station Committee of the Hawaiian Sugar Planters' Association, 1906 (*Hawaiian Sugar Planters' Sta. Rpt.* 1906, pp. 55).—The general work of the station during the year ended September 30,

1906, is reviewed by the committee in charge and more detailed reports of the officers in charge of the divisions of agriculture and chemistry, entomology, and pathology and physiology are appended. Some of these reports are abstracted elsewhere in this issue.

Eighteenth Annual Report of South Carolina Station, 1905 (*South Carolina Sta. Rpt. 1905*, pp. 28).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1905, and reports of the director and heads of departments.

Nineteenth Annual Report of South Carolina Station, 1906 (*South Carolina Sta. Rpt. 1906*, pp. 28).—This includes the organization list, a financial statement for the fiscal year ended June 30, 1906, and reports of the director and heads of the departments reviewing the work of the station during the year.

Interim report of the Canada Experimental Farms, December 1, 1905, to March 31, 1906 (*Canada Expt. Farms Interim Rpt., 1905-6*, pp. 98).—This report, issued primarily on account of a change in the date of closing the fiscal year, summarizes, in a general way, the more important results secured by the experimental farms since their establishment in 1887. Reviews of this nature are submitted by the director, W. Saunders, the agriculturist, J. H. Grisdale, the horticulturist, W. T. Macoun, the chemist, F. T. Shutt, the entomologist and botanist, J. Fletcher, the cerealist, C. E. Saunders, and the poultry manager, A. G. Gilbert. Although the report contains no new work, it is nevertheless of considerable interest, inasmuch as it outlines the progress that has been made in experimental agriculture in Canada during a period of about 19 years.

Experiment Station Work, XXXVIII (*U. S. Dept. Agr., Farmers' Bul. 273*, pp. 32, figs. 4).—This number contains articles on the following subjects: Loss of nitrogen from soils, manure as affected by food, continuous corn culture, pasturing wheat, storage of sweet potatoes, rotting of potatoes in storage, hog cots, the disinfection of stables, the effect of horsetail weeds on horses, treatment of calf scours, preserving eggs, wheat bran, testing individual cows, clean milk, cleanliness in the dairy, grading cream, and paraffin in dairying.

The experiment station building, A. Goss (*Indiana Sta. Circ. 4*, pp. 10, figs. 5).—The condition of the experiment station building is described and illustrated. An appropriation for a new building is being asked for.

NOTES.

Alabama College and Station.—In order to relieve the crowded condition at the college, the total enrollment of which has now reached 600 students, the legislature has made an appropriation of \$56,500 per year for the next four years to be used exclusively for buildings and equipment. Of this amount \$75,000 is to be expended in the erection and equipment of an agricultural building for the joint use of the college and station. In lieu of fees heretofore derived from the analysis of fertilizers, a fixed annual appropriation for maintenance has been made approximating in amount that previously obtained. The veterinarian of the college and station has been made *ex officio* State veterinarian. A live stock sanitary board has been created, with an annual appropriation of \$5,000. The greater part of this sum will be used in eradicating the cattle tick, the work being conducted in cooperation with the Bureau of Animal Industry of this Department.

California University and Station.—An appropriation of \$132,000 has been made by the State legislature for the equipment of the new farm at Davisville, and the establishment of an agricultural high school on its grounds.

Colorado College.—At the recent session of Congress a quarter section of land was ceded to the college for use in experiments in forestry.

Connecticut College and Stations.—In a special message to the legislature the governor advocated moving the agricultural college at Storrs to a more central and accessible site, and the State experiment station "to the same place, from its present too valuable site in an aristocratic residential section of New Haven, where land values are increasingly high." He asks that the legislature authorize the appointment of a special committee "to consider the problem of unifying, coordinating, and collecting the various agricultural forces of the State's related agrarian establishments and commissions," and recommends that only such appropriations be made for the agricultural college as are necessary to meet fixed charges due to the operation of the college during the next two years, all proposed improvements to await the report of the suggested committee.

A. L. Winton, chief chemist of the State station, has been appointed chief of the Chicago laboratory of the Bureau of Chemistry of this Department, in connection with the administration of the national food law, and has entered upon his duties. J. P. Street, chief chemist of the New Jersey stations, has been appointed to succeed him.

Delaware College and Station.—The State legislature has authorized the issuing of \$20,000 worth of State bonds, the proceeds of which are to be used for purchasing and equipping a farm for the use of the college and station. A legislative commission was appointed to purchase the farm and turn it over to the agricultural committee of the board of trustees. This commission has selected a farm of 220 acres, situated about a mile from the college.

At a recent meeting of the board of trustees it was decided to abolish the governing board of the station as at present constituted, and the agricultural committee was given control of all matters pertaining to the station and to the agricultural department of the college. Dr. C. F. Dawson, formerly of the

Bureau of Animal Industry, and more recently of the Florida University and Station, has been elected professor of veterinary science in the college and veterinarian to the station, and C. A. McCue, of the Michigan College, professor of horticulture and horticulturist. Dr. M. T. Cook, recently connected with the station in Cuba, has been appointed botanist of the college and plant pathologist to the station, succeeding F. D. Chester, resigned.

Illinois University and Station.—A laboratory of physiological chemistry has been established in the animal husbandry department of the college of agriculture. Dr. H. S. Grindley is to be in charge of this department, with the title of chief in animal chemistry, and assistants are to be provided for physiological, bacteriological, and analytical work. It is intended to confine the laboratory investigations entirely to studies in animal nutrition.

Indiana Station.—The legislature has appropriated \$100,000 for the erection and equipment of a station building. A feeding stuffs control law has also been enacted, to be in charge of the station, with a tax of 20 cents per ton to meet the expense. Any surplus revenue from this inspection is made available for general purposes.

Kansas College and Station.—Appropriations aggregating \$544,000 for the college and \$57,000 for the Fort Hays substation have been granted by the legislature for the next biennium. The appropriations include \$70,000 for the erection and equipment of a building for domestic science and art, a like sum for a veterinary building, \$80,000 for an engineering building, and \$11,500 for farmers' institutes. The aggregate is one-half as large as the entire amount given by the State during the previous forty-four years' history of the college. Bills were also passed providing for the inspection of feeding stuffs and fertilizers. The administration of these acts is to be in the hands of the station, which is authorized to collect a tonnage tax and apply the surplus for general purposes.

Louisiana University and Stations.—A small addition has recently been made to the pathological laboratory at the Baton Rouge Station for the purpose of giving additional room and better control of incubators and sterilizers. A hospital 26 by 20 feet, and a breeding room of the same size, are being erected for work in animal pathology. An Angus bull and heifer have recently been purchased for breeding purposes.

H. P. Agee, assistant chemist and sugar maker at Audubon Park, is spending the grinding season with one of the largest mills in Cuba.

A new chemical laboratory to cost \$40,000 is to be erected for the use of the university.

Maine University.—An appropriation of \$130,000 has been made by the legislature for maintenance during the next biennium, besides \$90,000 for new buildings, including an agricultural building and a central heating plant. A protracted contest to compel the abolition of the B. A. degree was unsuccessful.

Maryland Station.—Raymond Outwater, assistant chemist, died February 9. The vacancy has been filled by the appointment of Lewis W. Fetzer, Ph. D. (Munich), of New York. M. N. Straughn resigned March 1 to accept a position with the Bureau of Plant Industry of this Department, in connection with the sweet corn investigations. He will be succeeded as assistant chemist by J. J. T. Graham, at present assistant in the State work of the college.

Massachusetts College and Station.—James Draper, trustee of the college and for many years chairman of the committee on the experiment station, died March 14. C. S. Pomeroy has been appointed assistant horticulturist in the station, and E. C. Proulx, assistant chemist, has resigned to accept a position at the Indiana Station. The governor has approved the bill changing the name of the station to Massachusetts Agricultural Experimental Station.

A chair of floriculture has been established, and is to be in charge of E. A. White, now botanist at the Connecticut College and Storrs Station, who will enter on his duties at the close of the college year. Francis Canning, instructor in floriculture, has accepted a commercial position in Pennsylvania.

A summer school of agriculture for teachers is to be held, commencing July 8 and continuing four weeks. This is in line with the recommendations of the State Industrial Commission and recent acts of the legislature. Special attention will be given to the methods of teaching school and home gardening and general nature study.

Montana College and Station.—Increased appropriations for maintenance during the next biennium and for new buildings were made by the legislature at its recent session. The college received for maintenance \$50,000, an increase of \$14,000, besides an appropriation of \$80,000 for an agricultural building. For farmers' institutes \$15,000 was appropriated, an increase of \$7,000, and for the purchase of pure-bred stock, \$5,000. The station was given \$15,000 for maintenance and \$6,000 for experiments in dry farming, an increase in each case of 50 per cent.

A permanent substation for dry farming was established in Fergus County, with \$1,000 per year for maintenance. The county is to contribute 160 acres of land and at least \$3,000 for buildings. Cooperative work has been arranged for with the Bureau of Plant Industry of this Department and the cooperative work with the Northern Pacific and Great Northern railways will be continued, these corporations having offered to contribute from \$4,500 to \$5,500 for this purpose.

In response to a demand for fruit investigations \$500 was appropriated for the establishment of a horticultural substation. A perpetual water right and 15 acres of land must be given by the community in which it is located.

New Hampshire College and Station.—E. L. Shaw, associate agriculturist, has been appointed to a position in the Bureau of Animal Industry of this Department, and will take up the work July 1.

New York State Station.—M. P. Sweeney, of Colgate University, and P. W. Flint, of the Pennsylvania Station, have been appointed assistant chemists. A. W. Clark has resigned to take up commercial work.

Cornell University.—James G. Needham, Ph. D., professor of biology in Lake Forest University, and also connected with the New York State Entomological Field Station, has been appointed assistant professor of limnology in the department of entomology of the college of agriculture. His duties will include largely research work on the study of life in marsh and inland waters. It is said that the course has heretofore never been offered in any university.

North Dakota Station.—An annual appropriation of \$7,500 has been made by the legislature for additional bulletins, the establishment of 12 demonstration farms, experiments in the manufacture of denatured alcohol, and other purposes.

Ohio Station.—D. L. Sampson has been reappointed a member of the board of control. At its annual meeting T. C. Laylin was elected president, D. L. Sampson, secretary, and John Courtright, treasurer. A department of nutrition investigations was established under the direction of E. B. Forbes, of the Missouri University and Station, who is expected to begin his work during the summer. An extension of one of the station buildings has provided additional office facilities.

Oklahoma College.—The short course held this winter was an unprecedented success, there being about 500 farmers in attendance. The keynote of the meeting was agricultural education of the farmer, both at home and in college.

A plan for movable schools, suggested by Prof. John Hamilton of this Office, aroused special interest.

Pennsylvania College.—Gen. James A. Beaver, ex-governor of the State, judge of the superior court, and president of the college board of trustees, has been elected president of the college, and Dr. Judson P. Welsh, principal of the Bloomsburg State Normal School for many years, vice-president and business manager.

Rhode Island College and Station.—G. E. Adams, associate agronomist in the station, has been elected professor of agriculture in the college to succeed F. W. Card, whose resignation takes effect June 30. L. F. Whipple succeeds W. F. Purrington, whose resignation has been previously noted, as assistant chemist in the station.

South Carolina Station.—C. C. McDonnell has resigned as assistant chemist to accept a position in the Bureau of Chemistry of this Department.

South Dakota Station.—The legislature has passed a bill directing the selection of common school, endowment, or indemnity lands in 3 sections of the State for experiment stations. A bill was also passed granting 25,000 acres of land to these stations for their support.

Tennessee University and Station.—A State appropriation of \$100,000 has been made for the next biennium. Of this amount, \$25,000 is to be used for salaries, \$40,000 for an agricultural building, \$22,000 for repairs and equipment, \$3,000 for the transportation of the holders of scholarships, of which three have been established for each member of the legislature, and \$10,000 for cooperative experiments in agriculture and agricultural extension work in middle Tennessee. A separate bill also appropriates \$40,000 for the establishment of a permanent substation in West Tennessee.

Virginia College and Station.—A. M. Soule, dean of the college and director of the station, has tendered his resignation, to take effect September 1, at which time he will go to Georgia to take charge of the agricultural work at the university.

Utah College and Station.—J. A. Widtsoe has been elected to succeed W. J. Kerr as president of the college, and E. D. Ball director of the station in succession to P. A. Yoder.

Washington College and Station.—An appropriation aggregating \$575,754 has been made by the State legislature for the ensuing biennium. Of this \$130,000 is for a library and auditorium, \$125,000 for a general recitation building, \$25,000 for a domestic economy building, \$12,000 for an engineering laboratory for hydraulics and irrigation, \$11,000 for a wing to the veterinary hospital, \$12,000 for additional farm lands, \$7,000 for barns, \$10,000 for farmers' institutes, \$4,000 for investigations with cereals and in dry-land farming, \$2,500 for irrigation investigations, \$20,000 for the Puyallup Substation, and the balance for maintenance. A two-year forestry course has just been arranged, and a chair of farm management is to be established.

West Virginia Station.—E. B. Copeland, who, as previously announced, was elected horticulturist, has decided not to accept the position, but will continue in his present position with the Philippine department of agriculture.

Wyoming University and Station.—The property formerly belonging to the State penitentiary, which has been occupied by the university and station for some time, has been formally granted by the legislature to the university, together with an appropriation of \$5,000 for its equipment for experimental work. An appropriation of \$2,500 for farmers' institutes was also made.

Office of Experiment Stations.—C. B. Smith, for several years in charge of the departments of horticulture and forestry of *Experiment Station Record*, has

been transferred to the Farm Management Investigations of the Bureau of Plant Industry, and has been succeeded by E. J. Glasson of that Bureau. B. P. Fleming has been appointed irrigation engineer in the New Mexico Station.

New Experiment Station at Grignon.—An experiment station of vegetable physiology and pathology is to be established at Grignon, France, under the directorship of Doctor Griffon. It will be quite distinct from the agronomical station founded by Deherain, and will be devoted entirely to work with plants.

Commission on Organization and Policy in Agricultural Research.—President L. H. Bailey, of the Association of American Agricultural Colleges and Experiment Stations, has appointed the commission provided for at the last convention to inquire into the organization and policy which should prevail in the expenditure of public funds in agricultural research, as follows: As representatives of scientific men not connected with official agricultural research, President David Starr Jordan, of Leland Stanford University, and President Carroll D. Wright, of Clark College; from the research workers of the association, Dr. H. P. Arnsby, of the Pennsylvania Station, and Dr. W. H. Jordan, of the New York State Station; and from this Department, Gifford Pinchot, of the Forest Service. President Jordan is to be chairman of the commission.

Agricultural Measures Passed by Congress.—In addition to the agricultural appropriation act, which contained considerable legislation and is summarized elsewhere in this issue, provision was made for the establishment of an agricultural bank for the Philippines, the removal of certain restrictions on the manufacture of denatured alcohol, and for the printing of 250,000 copies of the report of this Department on the diseases of the horse. Agricultural colleges were also made depositories for all public documents. Among the measures which failed of passage were the various bills for the support of branch experiment stations, agricultural high schools, agricultural instruction in normal schools, and additional agricultural colleges in Congressional districts.

Agricultural School at St. Lawrence University.—Additional plans have been announced concerning this institution. According to *American Agriculturist* a school of secondary grade is contemplated, which will cooperate, rather than compete, with the college of agriculture of Cornell University. The leading objects will be the training of practical farmers and farmers' wives. A common school education will be required for admission, but there will be no entrance examinations. Particular attention will be given to the needs of northern New York. Special farmers' courses are contemplated, and various forms of extension work are to be carried on so far as practicable.

A tract of land adjoining the university has been secured for the school and negotiations are proceeding for a farm of 70 acres for experimental purposes. A main building is to be erected at once. This will be a substantial three-story stone structure, and will contain recitation and lecture rooms, laboratories, libraries, an assembly hall, and rooms for domestic science, manual training, and blacksmithing. It is hoped to undertake some instruction of a preliminary nature next fall and to have a formal opening in the spring of 1908.

K. C. Davis has accepted the position of dean which, as previously announced, was tendered him some time ago.

Graduate School of Agriculture in 1908.—The committee on graduate study of the Association of American Agricultural Colleges and Experiment Stations has decided to hold the next session of the graduate school at Ithaca in the summer of 1908. Dr. A. C. True, of this Office, has again consented to serve as dean.

Agriculture at Cambridge University.—The professorship in agriculture at Cambridge was established in 1899, in consequence of an offer by the Worshipful Company of Drapers to contribute \$4,000 a year for ten years for its support.

This offer has just been renewed for a second period of ten years, and the chair is henceforth to be designated the "Drapers' Professorship of Agriculture." As previously noted, the Drapers' Company has also offered \$25,000 toward buildings and equipment, for which \$100,000 is desired. From other sources \$35,000 has already been pledged. It is also hoped to increase the annual income by \$3,000, as the number of students in agriculture is rapidly increasing and additional aid is required. Efforts to establish a department of forestry are under way and a beginning has been made toward a forestry museum.

Rural Education in England.—At a special meeting of the Lincolnshire Chamber of Agriculture resolutions were passed urging that a more decided agricultural tone should be given to the teaching in the rural elementary schools, and that a complete and consecutive system of secondary education should be established in the rural districts.

The Lincolnshire Farmers' Union recently submitted to all candidates for the county councils in Lincolnshire a series of questions as to their attitude on the introduction of nature study into the rural schools, the keeping of school gardens, and the providing of more definite instruction in rural economy.

A New Experiment Station in the French Kongo.—An order has been issued for the establishment of the Trial Garden of Como at Agonenzork to investigate the culture of cacao and rubber trees. The garden is to be in charge of a sub-inspector of colonial agriculture. M. Buchet has been designated for this position and also as director of the Trial Garden at Libreville.

New England Conference on Rural Progress.—The first conference on rural progress in New England was held at Boston March 8. Its purpose was outlined by President Butterfield, of the Massachusetts Agricultural College, with whom the idea originated, as a demonstration of the unity of New England in its interests which make for progress. He urged especially closer cooperation of existing agencies, such as the State boards of agriculture, the agricultural colleges and experiment stations, the State federations of churches, State departments of education, and the grange. All of these interests were represented at the conference, the speakers, including E. D. Howe, of Massachusetts, and H. O. Hadley and N. J. Bachelder, of New Hampshire, for the grange; H. J. Wheeler, of the Rhode Island Station; G. H. Martin, secretary of the Massachusetts State Board of Education; L. R. Jones, of the Vermont University and Station; W. D. Hurd, of the University of Maine; E. T. Hartman, secretary of the Massachusetts Civic League; Rev. E. T. Root, field secretary of the Massachusetts Federation of Churches; G. M. Twitchell, of the *Maine Farmer*, and A. E. Stene, of the Rhode Island College. It was decided not to attempt a permanent organization at that time, but to hold another meeting in the spring of 1908, at which time a committee is to report a detailed plan of organization.

New Forestry Journal.—We note the establishment of the *Quarterly Journal of Forestry*, under the auspices of the Royal English Arboricultural Society in conjunction with the Irish Forestry Society, and edited by A. C. Forbes. The publication is said to be the result of the rapid growth of the first-named society, together with the increasing interest taken in all matters relating to forestry. The initial number includes the transactions of the Royal English Arboricultural Society, an explanation of the purpose of the Irish Forestry Society, current topics and articles, notes on practical forestry, and reviews and abstracts of forestry literature.

Second International Congress of Agricultural Mechanics.—Official announcement is made that this congress will meet as a section of the Eighth International Congress of Agriculture, to be held in Vienna May 21-25, 1907. Special attention is to be given to the establishment of uniform international rules for the examination of agricultural machinery, and a report on this subject is to be

submitted by a committee appointed at the last congress at Liège. Other problems to receive consideration will be the organization of exhibits and competitions of farm machinery and the promotion of conditions tending toward its more extensive use, and the development of instruction in agricultural mechanics. The secretary of the congress is Prof. Josef Hausler, Schlauffergasse 6, Vienna, to whom applications for registry should be addressed.

Argentine Republic to Test von Behring Treatment for Tuberculosis.—According to *Breeders' Gazette* the Argentine Republic is to make an extensive trial of the von Behring treatment for tuberculosis. P. H. Römer, an assistant of Doctor von Behring, has been secured for one year to equip a hospital in Buenos Ayres for the treatment of cattle in quarantine which have reacted to the tuberculin test on importation. Animals failing to respond to the treatment after six months will be destroyed. "Cures" will be kept under supervision for three years and then killed and given a thorough post-mortem examination. It is hoped in this way to decrease materially the present heavy losses from tuberculosis.

Boys' and Girls' Contests in Kansas.—An attempt is to be made to extend the boys' corn contest held last year in 47 of the 105 counties of Kansas to the entire State, and to arrange for additional boys' and girls' contests in growing dwarf milo maize, durum wheat, sugar beets, garden crops, potatoes, and flowers, and in baking, sewing, mending, and canning. This movement is under the supervision of the State superintendent of farmers' institutes, but the details of the contest will be left largely with the county organizations. It is recommended that the prizes consist in part of trips to the agricultural college at the time of the winter institutes and State contests.

Department of Nutrition of the Carnegie Institution.—The Carnegie Institution has decided to locate its laboratory for the study of problems in human nutrition in Boston, where a site has been obtained in close proximity to the new buildings of the Harvard Medical School and near several hospitals. The laboratory will contain a respiration calorimeter and is to be equipped with complete accessory apparatus.

Necrology.—Sir Michael Foster, the distinguished physiologist, author of the well-known Textbook of Physiology, and the successor of Huxley as Fuller professor of physiology in the Royal Institution, died January 29 in his seventy-first year. For twenty-two years he was secretary of the Royal Society of Great Britain, professor of physiology in the University of London since 1869, professor of physiology at Cambridge from 1883 to 1903, and since 1901 president of the Royal Commission on Tuberculosis. He was well known and held in high esteem in the United States, where he delivered a series of lectures on the history of physiology before the University of California.

J. Vilbochevitch, founder and editor of the *Journal d'Agriculture Tropicale*, died January 27. He was born at Bielostok, Russia, June 24, 1868, and educated at the Agricultural Academy of Moscow. In 1889 he made a study in France of alkali soils, their flora and culture, publishing a work entitled *Les Plantes Utiles des Terrains Salés* in 1892. On his return to Russia he assisted in the organization of the horticultural exposition in St. Petersburg, and was for several years attached to the Russian ministry of agriculture, studying reforestation and related problems. In 1901 he founded in Paris the *Journal d'Agriculture Tropicale*, which soon became an important factor in the development of tropical agriculture, particularly in the French colonies.

The death is announced of Prof. William von Bezold, director of the Prussian Meteorological Institute. In 1878 he was made director of the Central Meteorological station in Bavaria and organized the meteorological service in that country, remaining in that position until 1885, when he accepted the director-

ship of the Prussian Institute. Among his contributions to meteorology were papers on the thermo-dynamics of the atmosphere, which are the classical memoirs on that subject. He was also greatly interested in the theory of terrestrial magnetism.

Dr. Allen MacFayden, a distinguished English bacteriologist, died March 1, as the result of accidental infection in the laboratory. Among his investigations were studies of the bacteria in the digestive tract, bacteria thriving in high temperatures, and the effect of low temperatures on micro-organisms. He devised a method of grinding bacteria with liquid air and showed that the "endotoxins" thus obtained could be used for immunizing. The application of his results to the treatment of human diseases had occupied his attention in recent years. He was prominently connected with the establishment and management of the Lister Institute of Preventive Medicine, and from 1901-1904 was Fuller professor of physiology at the Royal Institution.

Dr. Guido Krafft, professor of agriculture in the technical high school at Vienna and a well-known agricultural writer and editor, died February 22, at the age of 62 years.

Miscellaneous.—We note from *Science* that a gift of \$400,000 has been received by Teachers College of Columbia University for a building for its school of domestic economy.

The Society for Horticultural Science and the American Pomological Society will hold their next meetings on the grounds of the Jamestown Exposition, September 25 and 26.

Dr. D. E. Salmon, formerly chief of the Bureau of Animal Industry of this Department, has sailed for Montevideo, Uruguay, where he will assume charge of the veterinary department in the university of that city.

A. F. Burgess, secretary of the Association of Economic Entomologists, has resigned as State inspector of orchards and nurseries for Ohio and taken up experimental work in Massachusetts with insecticides for the destruction of the gypsy and brown-tail moths.

Silas C. Mason, for several years professor of horticulture and forestry at Berea College, Kentucky, has resigned to accept a position in the Bureau of Plant Industry of this Department, in connection with the work upon plant life history. He has been sent to Arizona, where he will make a field study of plants of economic importance in the semiarid and arid regions.

The Goldsmiths Company has given \$50,000 to the Rothamsted Experiment Station for investigations on soils.

A subscription has been opened in Austria for the erection of a monument to Gregor Mendel, the discoverer of the laws of heredity bearing his name. Prof. E. von Tschermak is president of the committee, the American members of which are W. A. Cannon, Desert Laboratory, Tucson, Ariz., and C. B. Davenport, Cold Spring Harbor, N. Y.

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau requests and remittances should be directed to the Chief of the Bureau. The price of the Record is \$1 per volume, or 10 cents per number. The prices of other technical publications are given in the list above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XVIII.

MAY, 1907.

No. 9.

The completed plans of the experiment stations for investigations under the Adams Act contain much of interest and encouragement to all who have a high ideal for experiment station work. These plans have been worked out with unusual care and deliberation, and, taken as a whole, they embody a large amount of investigation in the true sense, which will place agricultural science and research upon a higher plane. Considering the conditions under which the first year's work had to be planned, the difficulties of securing men, the lack of uniform standards, and the like, the programme must be regarded as very satisfactory.

While it is not planned to publish the projects presented by the different stations, a review of the list as a whole, with some of its salient features, will indicate the character and high grade of the work proposed, and the broad field which these investigations cover. When it is considered that most of the subjects are to be studied through a period of several years and that the plans for many of them will be further developed as the investigation progresses, it will be evident that a new régime has been entered upon in the conduct of our stations, which will make them contribute in a large way to the unfolding of the principles upon which agricultural development and practice rest. Not only is the amount of investigation vastly increased, but the outlining of the various undertakings in advance has had the effect of systematizing our work more thoroughly than ever before, and ultimately this should reflect favorably upon the activities of the station as a whole.

As was natural to expect from the present interest in the subject, a large number of projects were proposed in plant breeding. Investigations in this line must, of course, discriminate clearly between random efforts at improvement in a broad way and the more systematic effort to attain a definite end. Breeding for improvement should have an ideal in view and be conducted in the endeavor to attain that object in a scientific way, taking advantage of all that is known, and keeping such records that the manner in which the ultimate result is attained can be definitely described. The element of

chance is prominent enough in plant breeding at best. The breeding work projected under this new fund has been given a definiteness of purpose, has been restricted to limits within which it could be carefully followed, and in a considerable number of instances has been so planned as to contribute to a better understanding of the principles of breeding.

It is proposed, for example, to make thorough studies upon heredity in plants, the variability in morphological characters in cultivated wheat, the extent of hybridizing in nature and the environmental conditions associated therewith, effects of external environmental factors upon heritable morphological characters, and the correlation of visible morphological characters with the presence and distribution of such constituents as gliadin, glutenin, and starch in the grain. Corn breeding for the semiarid region is being taken up from the standpoint of the factors which constitute drought resistance as a basis for such breeding, and the development of immune or disease-resistant strains of crops on the basis of studies upon what constitutes immunity in different cases, and the principles underlying development of disease resistance. These physiological studies will take up anatomical and chemical phases of the subject, such questions as the functions of tannin in the economy of the plant, its presence in pathological tissues, effect on parasites, etc.

In general, the pathology and physiology of disease is to be studied in a more comprehensive way than heretofore, taking up such matters as the relation between the character of the soil and certain diseases, notably the relation of marly soils and of lime to chlorosis of citrus fruits, the specific influence of the different factors which go to make up climate upon health and susceptibility to disease, and the relation of nutrition to the latter. Naturally a quite large number of plant diseases are to be made the subject of systematic study. In some cases these are new or little understood diseases, and in others the object is to clear up doubtful points as to the organisms inducing them, their life cycle, relationships, susceptibility to various influences, means of dissemination, etc., as a more intelligent basis for combating them. There is opportunity for much profitable work of this kind, for in the pressure for results which should indicate remedies to be applied it has often been impossible to go as deeply into the nature and cause of the disease and the influences affecting it as is clearly desirable.

The same is true to a considerable extent in the case of economic insects, and the use of sprays and other treatment. Now that the opportunity is offered, it is found desirable to go back to some of our most common insect pests and study more thoroughly certain points in their habits and life histories, environmental conditions which affect them, and similar matters, as bearing ultimately on

methods of control. The entomological work proposed is, as a whole, of high order, indicating for the most part a clear conception of the features of research and an appreciation of its importance as applied to that branch of science. The list of projects is also relatively large and varied. Several investigations have to do with the toxicity of various insecticides, the manner in which they act, and similar points, as well as their physiological effects on the trees and plants receiving the treatment.

The number of investigations proposed in horticulture, aside from those in breeding, is not large, a fact which is somewhat disappointing in view of the opportunities which this division of agriculture presents for thorough investigation and the undeveloped state of horticultural science. There are several physiological studies, however, which are of special interest and importance, such as the causes and means of control of fruit-bud formation on the apple, the physiology and philosophy of pruning and of grafting, both of which as planned involve extensive systematic studies, the elimination of the color of peach twigs by breeding to make them less susceptible to early frost, the factors affecting the setting of fruit on the tomato, to determine the cause of failure to set in dry localities where the plants bloom freely, and other studies of the effect of environmental conditions.

The subject of dry farming, in which there is such active interest of late, naturally suggested a considerable number of projects, and here the necessity for the differentiation for scientific study is well illustrated. Dry farming, like farm management, is evidently not a division of agricultural science, but rather a branch of agricultural practice conducted under certain climatic conditions. The furnishing of a more scientific basis for it in place of the results of simple tests and demonstrations must depend upon investigations in chemistry, physics, agronomy, physiological botany, plant breeding, and various other lines, as related to definite phases of the general subject. Hence a number of special investigations have been undertaken, such as the absolute water requirements of plants, the periodicity of this requirement, the water-holding capacity of the soil and factors which affect it, the conservation of the soil moisture, the breeding of drought-resistant crops, and the like. Many of the problems in dry farming are mechanical and purely local, and the more general trials and demonstrations have been left to other funds.

Soil fertility is another topic which has attracted much investigation on account of the renewed interest in the subject; but here, as in dry farming, the necessity for differentiation of the broad subject has been apparent. The large number of soil investigations is a noteworthy feature of the list of projects. Aside from studies of the fertilizer requirements of soils by field and laboratory methods, and

the composition of certain crops as indicative of these requirements, the work includes the nature and extent of the influence exerted upon crops by the previous growth of other kinds of plants, the relation between soil conditions and the quality of crops, such as the staple of cotton, the effect of sodium salts applied to the soil upon the organic and inorganic constituents of plants, the rôle of phosphorus and of potassium in plant nutrition, and the rôle of lime in the soil.

There are also several projects dealing with humus, its nature and determination, relations to soil fertility, rate of formation under different conditions, behavior and conservation in the soil, and effect of various factors on the humus content. To these are added studies in soil bacteriology as related to humus formation and change, relation of microscopic life of the soil to fertility in general, nitrifying and other biological properties of the soil, determination of the number, character, and biochemic functions of bacteria within the zone of tillage, to ascertain the part these organisms play singly and collectively in the setting free of plant food, and the bacteriological conditions in irrigated and unirrigated soil in the arid region, with special reference to the formation of nitrates and to the decomposition of barnyard manure. The number and character of these investigations give much encouragement for a better understanding of the complex factors which go to make up soil fertility and adaptation.

Closely related to these studies are various chemical investigations on plants and their products, such as the nonsugars in sugar cane, their nature and amount, and the conditions which affect their formation, with special reference to sugar manufacture; the gluten content of wheat, cause of its deterioration and methods of correcting, the milling qualities of wheat as related to this and other factors, and the factors affecting the lupulin, volatile oils, and other active principles of hops. An investigation of the various sugars and coloring matters in cacti is also in progress, and the rationale of the ripening of the date is to be taken up.

Animal nutrition does not claim a large number of investigations, but these are of quite a different type from the ordinary feeding and digestion experiments to which the work has in the past been quite largely confined. Digestion experiments have been undertaken with reference to some particular point, rather than the determination of digestion coefficients for themselves. Among these are the behavior of the constituents of the nitrogen-free extract in digestion and their relation to nutrition, the influence of certain feeding stuffs in depressing the digestibility of rations, and the nature and cause of this effect, the process of digestion as influenced by certain factors, and the effect of treatment or preparation of the feed on the digestibility of its constituents. Among the fundamental studies in animal nutrition are the influence of age and individuality on metabolism in cattle, an

extensive investigation upon the use which animals actually make of their food at different periods of growth, considered from a physiological standpoint, the rôle of phosphates in animal nutrition, the effects and importance of various other mineral constituents, and the specific effect of certain foods on the product, such as the hardness or solidity of pork and the character of the fat in butter.

In dairying there are also comparatively few projects, which may be taken as an indication that attention is being turned in that direction far less than a few years ago, or that men are lacking to take up the more fundamental problems in this field. There are several quite elaborate projects dealing with the less understood properties of milk and their relation to differences in its nutritive value and the manner in which it agrees with people, but aside from these the dairy work is quite largely on the bacteriological side. Investigations are proposed upon bacteria other than disease germs in milk which are detrimental to digestion, the leucocytes in milk under normal and abnormal conditions and their sanitary significance, the constituents of cheese and their changes under the influence of certain classes of bacteria, and bacteriological and chemical investigations upon the disposal of creamery sewage, which is found much more resistant than municipal sewage, necessitating modification of the septic tank method.

In animal breeding investigations are to be made in heredity and upon the effects of inbreeding, the latter being planned to be the most systematic attempt ever made to study the effects of inbreeding upon domestic animals. In other investigations the breeding of animals under normal and abnormal conditions is to be studied, the effect of certain feeds like cotton-seed meal upon prepotency, and the whole problem of artificial impregnation. It is encouraging to see the breeding of animals taken up in a way to contribute more exact and reliable knowledge. Several other investigations in that field are being planned.

Veterinary science presents quite a list of undertakings of a thorough character relating to specific diseases, the immunizing of animals, with a study of the causes of natural immunity, stable ventilation in relation to the requirements of health, the active principles of plants poisonous to stock, and several quite elaborate studies upon the life history of the cattle tick as related to Texas fever eradication.

Several less usual topics are a study of the conditions in the incubation of eggs under the hen as regards gases and physical factors, and their reproduction in artificial incubation; the optimum conditions for artificial incubation in dry climates; conditions determining the egg-laying capacity of fowls, and the fertility of eggs; the cause of decay in eggs; and an investigation into the factors influencing wool production, the scouring of wool, and related topics.

This list is in no sense a complete one in scope or extent, and only hints at some of the salient features of the programme for investigation. It serves to show something of the variety of topics undertaken, and indicates in a general way the character of the work. It will be evident that the subjects have been selected in a discriminating manner, and are being attacked in a way to give a scientific answer which will disclose the various factors which are operative and something of their relative importance. In this respect a large proportion of the work is undertaken from a somewhat different point of view from that which has more commonly prevailed, and there is evident intention to systematize the inquiry and make it thorough as far as it goes. There is an absence of experiments or trials which aim solely at an immediately practical answer, without regard to the scientific aspects of the case. Throughout the list of projects there is an attitude of inquiry, an attempt to get at the reason for results and phenomena, in order that deductions and generalizations may be made on a sound basis of science.

The working out of these projects in considerable detail has in itself been a somewhat new experience for a considerable proportion of station men, whose work has not always been characterized by a systematic and well-digested plan. The plan has frequently grown up with the experiment itself, and this has affected the conduct of the work at different stages and necessarily the final result. If the system inaugurated for the Adams fund projects shall become more generally applied to the station work as a whole it will be an important result of the first year's operations under the new act. Its advantage to the station worker and in the administration of the station must be evident. Only by some such means can the director keep informed upon the work of various departments, arrange for necessary cooperation to strengthen the investigations, and follow up the investigations from year to year.

One of the great needs of our stations has been a more thorough systematizing of their work—not that the individual initiative of the workers is to be restricted or the position of the workers subordinated in any way; but viewing the work of the past it must be evident that quite a proportion of the station work has lacked in efficiency from not having a sufficiently definite aim and thoroughly considered plan, and not having the necessary continuity. Frequently much well-planned work has been interrupted or dropped before results of any value could be secured; and on the other hand the value of many experiments has been largely nullified by lack of support from some other department of the station. The control of these matters, so vital to the efficiency of station work, is an administrative function, and more than any other single thing calls for the guidance and inspiration of a competent administrative officer. The

interruption of experiments and investigations is by no means always attributable to the station worker, or to the director himself, but with a more systematic arrangement of the station work, and a closer and more sympathetic contact with it, many of the present disturbing factors might be avoided.

Now that every station has given serious attention to the planning of research and has made that an important phase of its activity, attention may well be turned to the strengthening of the station organization for such work and the bringing of the station work as a whole into harmony with it.

In a recent article, Doctor Pritchett, speaking of another subject, says: "Perhaps at our present stage of development in such matters no other preliminary work needs more to be done than some work of popular education relative to what research is." This applies with peculiar force to the subject of agriculture. "Our ideas are not yet entirely clear as to what research in agriculture really is, and the general public has only the faintest glimmer of its importance in comparison with other grades of work. Systematic effort will therefore be needed to develop an intelligent appreciation of research in agriculture and of its ultimate importance in making real progress possible.

The death of Prof. Robert Warrington, at Harpenden, England, on March 20, will call to mind the excellent course of lectures given before the Association of American Agricultural Colleges and Experiment Stations in 1891, by the first representative sent to this country under the provisions of the Lawes Agricultural Trust. Professor Warrington made many friends on that occasion, who gained from him inspiration for exact and painstaking investigation, as well as a clearer insight into the plan and method of the systematic work at Rothamsted. The news of his death will be received with much regret.

From an article in *Nature*, by the present director of the Rothamsted station, it is learned that Warrington was born in 1838, being the son of a chemist of prominence, from whom he learned his first chemistry. In 1859 he worked for some time as a voluntary assistant in the Rothamsted laboratory, and in 1862 went to the Royal Agricultural College at Cirencester as assistant to the late Dr. Augustus Voelker. In 1867 he became chemist at Sir John Lawes's tartaric acid works, and in 1876 returned to Rothamsted, where he remained until 1890.

"On his return to the Rothamsted laboratory in 1876, Warrington introduced several improved methods of analysis to save time or insure greater accuracy in the routine determinations; there also he carried out the investigations on nitrification by which he made his name. In 1877 appeared the paper of Schloesing and Müntz,

which showed that the production of nitrates in the soil must be due to living organisms. This work was repeated by Warington, who continued to investigate the conditions favorable to the process. He showed that light would inhibit the change and that the drying of the soil was sufficient to destroy the organism: he also investigated the distribution of the organism, and showed that it was confined to the surface layers of ordinary soil, being only present in any quantity in the portion usually stirred by the plow.

“Observing that the oxidation of the ammonia or urea employed sometimes stopped at the stage of nitrite, he succeeded in demonstrating that the process in ordinary soils takes place in two stages due to different organisms—one oxidizing ammonia to nitrous acid, the other completing the oxidation to nitric acid. Warington had actually accomplished the final step in the isolation of the two organisms, though he had not brought his work to the stage which satisfied himself, when his researches were unfortunately interrupted, and before he could resume Winogradsky published his elegant method of isolating the nitrous and nitric organisms by the use of a nutrient silica jelly. The circumstances which led to Warington thus missing the credit of the crowning point of his long researches on nitrification undoubtedly caused him bitter disappointment. He continued to live in Harpenden, but took no further part in research.

“In the course of his investigations on nitrification, Warington also observed and studied that other process of denitrification, by which previously formed nitrates are reduced again, often with loss of the nitrogen as gas. In later years this subject became very prominent for a time, but the essential conditions of the action had been laid down before in Warington's papers. He also investigated the method of estimating small quantities of nitrates by means of indigo, and devised a standard process which, in a simplified form, is now used by most water analysts. . . .

“Warington's scientific work is distinguished by clearness and precision. The range is not wide, but everywhere it shows the minute care and the regard for accuracy with which he worked. In these respects his work only reflected his personal character.”

He was Sibthorpeian professor of rural economy at Oxford from 1894 to 1897, a chair held for several years by Sir Henry Gilbert. His little book on the Chemistry of the Farm, first published in 1881, has gone through fifteen editions. He was a fellow of the Royal Society and the Chemical Society, being vice-president of the latter from 1889 to 1893. Since 1894 he had been examiner in agricultural science to the board of education.

Professor Warington's health began to fail about a year ago, when he underwent an operation, which greatly benefited him for a time, but eventually a recurrence of the malady led to his death.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

A single standardizing material for acidimetry and alkalimetry, E. RUPP (*Chem. Ztg.*, 31 (1907), No. 9, p. 97).—The author tested with success and recommends for this purpose weak solutions (preferably tenth-normal) of carefully purified borax to which glycerin or mannite is added.

On the rapid determination of carbon dioxide in confined and free atmospheres, A. MÜNTZ, E. LAINÉ, and R. GALLOIS (*Ann. Inst. Nat. Agron.*, 2. ser., 5 (1906), No. 1, pp. 13–30, figs. 4).—A titrimetric method is described in which the carbon dioxide evolved is absorbed in dilute alkali, the excess of alkali being titrated with a solution of sodium bicarbonate, using Poirrier's blue as an indicator. By means of a special apparatus, which is fully described, the carbon dioxide as it is evolved is made to pass through the alkali solution very slowly and in a very fine state of division, thus insuring perfect absorption. The fine division of the gas bubbles is secured by means of a special device which forces the gas to pass through a soap solution.

The method was successfully applied to confined air and to the free atmosphere in the garden of the National Agronomic Institute at Paris. In a series of observations in the latter case the amount of carbon dioxide in the atmosphere varied from 2.87 to 3.24 parts per 1,000.

On a new method for the determination of ammonia in waters, A. BUISSON (*Compt. Rend. Acad. Sci. [Paris]*, 144 (1907), No. 9, pp. 493–495; *abs. in Rev. Sci. [Paris]*, 5. ser., 7 (1907), No. 11, p. 338).—The method is based upon the fact that if mercuric chloride is added to a solution of an ammonium salt containing sodium carbonate in the proportion of 5 molecules of mercuric chloride to 2 molecules of the ammoniacal salts ammonia is completely precipitated in the form of a white amorphous compound having the formula $\text{CO}_3(\text{Hg}_2\text{N}_2\text{Cl}_2)_2\text{O} + 3\text{H}_2\text{O}$.

The method is carried out as follows: Add 5 cc. of a 1:4 soda solution to 1 liter of water and distill about 100 cc. into 10 cc. of 1 per cent hydrochloric acid, make the volume to 1 liter, add 10 cc. of a 5 per cent solution of mercuric chloride and 10 cc. of a 15 per cent solution of sodium carbonate, let stand for 24 hours, collect on a tared filter, wash with 5 cc. of water, dry at 100° C., and weigh. The weight thus obtained multiplied by 0.03 gives the ammonia in 1 liter of water. With water containing less than 1 mg. of ammonia per liter, precipitate in the 100 cc. distillate without dilution.

The results by this method are claimed to be as good as those by ordinary methods.

The determination of manganese in drinking water, H. LÜDRIG and W. BECKER (*Pharm. Centralhalle*, 48 (1907), No. 8, pp. 137–142).—The Knorre method, based upon the precipitation of the manganese by ammonium persulfate in boiling solution, dissolving the precipitate, and titrating the solution thus obtained, is recommended.

A delicate reaction for carbohydrates, H. J. H. FENTON (*Proc. Cambridge Phil. Soc.*, 14 (1907), No. 1, pp. 24–26).—It has been observed that when bromo

or chloro compounds of typical carbon radicals are acted upon by sodiomalonic ester in alcoholic solution considerable heat is evolved and the mixture turns bright red. When poured into water it gives a solution which exhibits an intense blue fluorescence.

"By taking advantage of the highly sensitive reaction with malonic ester, one may detect the merest trace of bromo-methyl-furfural and this test may consequently serve for the identification of all hexoses, whether aldose or ketose.

"The mode of operating is as follows: A minute quantity of the solid substance to be examined is slightly moistened with water, mixed with a drop or two of phosphorus tribromid gradually heated on a water bath to 90 to 100°, and kept at this temperature until the mixture has turned dark colored. It is then cooled, stirred with a little alcohol and a few drops of malonic ester; alcoholic potash is then added until the solution is alkaline. On now diluting the resulting mixture with a large volume of water, or alcohol, the fluorescence is at once apparent.

"The reaction is strongly marked even with the aldoses, but is, as might be expected, more intense with ketose sugars and with cellulose. In comparison with the other pure hexoses examined, galactose appears to give the weakest indications. . . .

"A saturated aqueous solution of hydrogen bromid may be employed in this test instead of phosphorus tribromid; the latter is, however, preferable in the case of substances which are less readily attacked, such as cellulose. The chlorids of phosphorus may also be used, but their action is perhaps less certain.

"Positive results were obtained with dextrose, levulose, galactose, sorbose, cane sugar, maltose, lactose, raffinose, starches, dextrans, cellulose in different forms, salicin, amygdalin, and the mixture of sugars resulting from the condensation of glycollic aldehyde.

"No indication was given by arabinose, xylose, glycollic aldehyde, mannitol, erythritol, glycerol, gluconic acid, mucic acid or inosite.

"It appears, therefore, that this test may be used for the identification of all hexoses or of other carbohydrates, glucosides, etc., which yield hexoses on hydrolysis."

In the author's opinion, this reaction possesses some advantages over the usual color reaction for carbohydrates in that the effect is restricted to the hexose or polyhexose nucleus.

On a characteristic reaction of milk with sodium or potassium hydroxid, F. KRÜGER (*Ztschr. Physiol. Chem.*, 50 (1907), No. 4-5, pp. 293-302).—The addition to cow's milk of one-fifth its volume of a 40 per cent solution of sodium or potassium hydroxid was found by Gautier and Morel to produce a cherry-red color in 24 hours. The same reaction was obtained with heated as with raw milk. It was not obtained by the use of ammonia. The author concludes from the results of his studies of this reaction that the color does not depend entirely upon the presence of proteids and lactose, but also upon one or more other constituents of the milk.

Contribution to the analysis of milk, E. CARLINEANTI and G. PIERANDREI (*Arch. Farmacol. Sper. e Sci. Aff.*, 6 (1907), No. 1, pp. 26-34).—Determinations of the specific gravity and the nitrogen content of milk serum obtained by means of rennet are considered valuable in detecting the adulteration of milk. The article has special reference to detecting the adulteration of cow's milk with the whey from goat's milk.

The determination of lactose in milk, C. PORCHER (*Rev. Gén. Lait*, 6 (1906), Nos. 3, pp. 49-56; 4, pp. 73-85).—The author describes various methods employed for this purpose, concluding that the most generally acceptable method

consists in treating the milk with mercuric nitrate and titrating against Fehling's solution.

The application of cryoscopy to the analysis of milk, E. GRÜNER (*Ann. Ist. Agr. [Milan], 6 (1901-1905), pp. 27-50*).—The freezing point of fresh cow's milk varies, according to the author, between -0.535 and -0.580° C. The variations for mixed milk are usually within -0.55 and -0.57 . The freezing point was not influenced by the age of the animals, the stage of lactation, or the feeding stuffs used. A slight influence, however, was attributed to the breed. The freezing point was not materially affected by the composition of the milk. Taken in connection with chemical analysis the determination of the freezing point is believed to afford valuable data in detecting the adulteration of milk with water.

The detection of added water in milk, C. REVIS (*Jour. Roy. Inst. Pub. Health, 15 (1907), No. 1, pp. 39-42*).—The author calls attention to the fact that when genuine milk is deficient in solids-not-fat the deficiency is due to an abnormally low percentage of milk sugar. In endeavoring to ascertain the cause of deficiency in the percentage of solids-not-fat in milk, it is, therefore, considered desirable to determine the amount of sugar. The difficulty lies in making the analysis before much of the milk sugar is decomposed. Adulteration with water is indicated when the amount of sugar is approximately $\frac{1}{2}\frac{3}{4}$ of the solids-not-fat, the total amount being less than 8.5 per cent. When the amount of sugar is considerably less than $\frac{1}{2}\frac{3}{4}$ of the solids-not-fat, the reduction in solids-not-fat is apparently due to natural causes.

Contribution to the refractometric detection of added water in milk, E. ACKERMANN (*Ztschr. Untersuch. Nahr. u. Genussmit., 13 (1907), No. 4, pp. 186-188, fig. 1*).—The value of determining the refractometer number of milk as a means of detecting adulteration with water is pointed out. In the author's method the serum is prepared by adding 0.25 cc. of a calcium chlorid solution (specific gravity, 1.1375) to 30 cc. of milk. This is thoroughly mixed and heated in a water bath for 15 minutes. The loss of water in the sample is prevented by means of a return-flow condenser.

With normal milk the author obtains constant numbers with the Zeiss immersion refractometer varying between 38.5 and 40.5. The addition of 5 to 50 per cent of water caused, according to the results reported, a reduction in this number of from 1.3 to 8.1.

The temperature correction of the Zeiss butyro-refractometer, H. D. RICHMOND (*Analyst, 32 (1907), No. 371, pp. 44-46*).—The following are offered as the most probable corrections:

Temperature.	Correction for scale reading.	Correction for refractive index.
15 to 20° C ...	0.620	0.000372
20 to 25° C600	.000372
25 to 30° C608	.000380
30 to 35° C615	.000393
35 to 40° C594	.000386
40 to 45° C585	.000380
45 to 50° C583	.000385

The Tolman and Munson factor 0.000365 for correcting refractive indices is, therefore, considered inaccurate. The author gives directions for the construction of a correction chart which it is claimed will give very accurate readings for all refractive figures and all temperatures.

A means of distinguishing cocoanut oil from butter and other fats and oils, J. HANUŠ (*Ztschr. Untersuch. Nahr. u. Genussmit., 13 (1907), No. 1, pp.*

18-24).—The method suggested tentatively in this preliminary communication depends upon the formation, separation, and saponification of the esters.

To 5 gm. of the melted fat is added 30 cc. of a tenth-normal alcoholic solution of sodium hydroxid. The mixture is thoroughly shaken, allowed to stand for 8 minutes, and neutralized with dilute sulphuric acid. It is then made up to 145 cc. with water and distilled, the alcoholic distillate of 30 cc. being kept separate from the aqueous distillate of 100 cc. The two fractions are washed into Erlenmeyer flasks, alcohol is added to the aqueous fraction, the free acids in both are neutralized, and saponification is effected by the addition of 40 cc. of tenth-normal sodium hydroxid and heating with a return-flow condenser for 45 minutes. The mixture is then titrated against tenth-normal hydrochloric acid, the difference between the number of cubic centimeters required for neutralization and 40 showing the number of cubic centimeters of the tenth-normal sodium hydroxid required for saponifying the esters in 5 gm. of fat.

The highest number of cubic centimeters required for saponifying the esters in the aqueous fraction was 10 in the case of pure butter, while it was very much in excess of that for cocoanut oil.

Detection of cocoanut oil in butter, F. VON MORGANSTERN and W. WOLFFRING (*Ztschr. Untersuch. Nahr. u. Genussmittel*, 13 (1907), No. 4, pp. 184, 185).—The method of Wijsman and Reijst (E. S. R., 17, p. 834) was applied by the authors to 20 samples of pure butter, the results showing no constant relation between the first and second silver numbers. In the majority of cases, however, the second silver number was higher than the first. This, according to the conclusions of Wijsman and Reijst, would indicate adulteration with cocoanut oil, which was not the case.

The silver index method of Wijsman and Reijst, H. SVOBODA (*Ztschr. Untersuch. Nahr. u. Genussmittel*, 13 (1907), No. 1, pp. 15-18).—This method proposed for the detection of cocoanut oil in butter (E. S. R., 17, p. 834) was applied by the author to 80 samples of pure butter. The Reichert-Meißl number with a distillate of 110 cc. averaged 27.29 and with a distillate of 300 cc., 31.03. The first silver index averaged 3.64 and the second 3.91. In 57 of the 80 determinations the second silver index was higher than the first, which was contrary to the results obtained by Wijsman and Reijst. This method is, therefore, considered of no value as a means of detecting the adulteration of butter with cocoanut oil.

On the determination of fat in cheese by the Gerber method, A. SCALA (*Staz. Sper. Agr. Ital.*, 39 (1906), No. 8, pp. 734-737).—Comparative determinations were made with the gravimetric method, the Gerber method, and the Siegfeld modification of the Gerber method. The results by the Gerber and Siegfeld methods were above those by the gravimetric method in 16.6 and 45.21 per cent, respectively, of the 42 determinations made and below in 83.33 and 54.76 per cent.

The chemistry of flesh. V, Methods for the determination of creatinin and creatin in meats and their products, H. S. GRINDLEY and H. S. WOODS (*Jour. Biol. Chem.*, 2 (1907), No. 4, pp. 309-315).—Using the colorimetric method described by Folin (E. S. R., 17, p. 165), determinations of the creatin and creatinin in a number of samples of meat and commercial meat extracts are reported. According to the authors, the colorimetric method employed has been successfully used with uncooked and cooked meats, meat products, and drippings. Recorded data show marked differences in the total amount of creatin and creatinin contained in different commercial extracts now on the market.

“Experiments upon meat extracts prepared upon a small scale in the laboratory, from fresh meat, are now under way to find out, if possible, the conditions

which produce the above difference in the relative proportion of creatinin and creatin."

Agricultural chemistry during the second half year of 1906, W. ZIEL-STORFF (*Chem. Ztschr.*, 6 (1907), No. 4, pp. 65-70).—Recent investigations relating to the nutrition of plants and animals are briefly reviewed.

Abstracts from current literature upon industrial chemistry, F. H. THORP (*Jour. Amer. Chem. Soc.*, 29 (1907), No. 3, pp. 349-382).—The part of this review of special interest to agriculture is that relating to the literature of electro-chemical fixation of nitrogen, fats and oils, fermentation, foods, sugar, and fertilizers (silica as a plant food).

Progress in cellulose chemistry, W. VIEWEG (*Chem. Ztg.*, 31 (1907), No. 8, pp. 85-87).—A summary of recent literature on the chemistry of cellulose.

The present development of the analysis of tanning materials, H. R. PROCTER and H. G. BENNETT (*Jour. Soc. Chem. Indus.*, 26 (1907), No. 3, pp. 79, 80).—This discusses the preparation of hide powders and gives the details of a method for the determination of tannins which, it is urged, should be adopted by the associations interested in this work.

Annual report of the government analyst for 1905-6, P. CARMODY (*Ann. Rpt. Govt. Analyst [Trinidad]*, 1905-6, pp. 16).—The report includes analyses of milk, a grass (*Rottboellia cruttata*) considered of some agricultural importance, banana stalks, a weed known as cane killer (*Alectra brasiliensis*), water, rum, and other materials.

Van Nostrand's chemical annual, 1907, edited by J. C. OLSEN (*New York: D. Van Nostrand Co.*, 1907, pp. X+496).—This is the first issue of a reference book consisting for the most part of numerical data. There are in all 93 tables which give the atomic weights, physical constants of the elements, calculation of volumetric and gas analyses, specific-gravity tables, equivalents of weights and measures, etc. In addition there are classified lists of the more important articles and books which have been published since January 1, 1905.

METEOROLOGY—WATER.

The meteorological elements and their observations in their relation to weather and climate, O. MEISSNER (*Die meteorologischen Elemente und ihre Beobachtungen, mit Ausblicken auf Witterungskunde und Klimalehre*. Leipzig and Berlin: B. G. Teubner, 1906, pp. VI+94, figs. 33; rev. in *Nature [London]*, 75 (1907), No. 1946, p. 366).—This is a text-book intended for higher schools and for self-instruction.

The question of the reorganization of the public weather service, GROHMANN (*Mitt. Deut. Landw. Gesell.*, 22 (1907), No. 6, pp. 43-45).—The weather predictions of the German weather service of particular agricultural interest are explained and their utilization briefly discussed.

Monthly Weather Review (*Mo. Weather Rev.*, 34 (1906), Nos. 11, pp. 505-555, figs. 15, charts 14; 12, pp. 557-607, figs. 16, charts 8).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of November and December, 1906, progress of climatology throughout the world, recent papers bearing on meteorology, recent additions to the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 11.—Records of the Difference of Temperature Between Mount Royal and McGill College Observatory, and a Method of Local Temperature Forecasting (illus.), by C. H. McLeod; Studies on the Thermodynamics of the Atmosphere—IX. The Meteorological Conditions Associated with the Cottage City Water-

spout—Continued (illus.), by F. H. Bigelow; Climatological Reports from the Philippines; Lunar Rainbow at Tampa, Fla., by J. S. Hazen; The Origin of Our Cold Waves; Meteorology in Austria; Mountain Stations for Forecast Work; Weather Bureau Men as Educators; The Study of Practice Forecasting, by J. L. Bartlett; The Evaporation of Ice, by F. C. Mitchell; and Harmonic Analysis of the Diurnal Barometric Curve at Washington, D. C. (illus.), by W. J. Bennett.

No. 12.—Salton Sea and the Rainfall of the Southwest, by A. J. Henry (see p. 815; Changes of Latitude and Climate; Tornadoes of June 6, 1906, in Minnesota and Wisconsin; Studies on the Thermodynamics of the Atmosphere—V. The Horizontal Convection in Cyclones and Anticyclones (illus.), by F. H. Bigelow; Villard's Theory of the Aurora (illus.), by W. R. Blair; Observations of Halos in England, by M. E. T. Gheny; Problems in Meteorology (illus.), by C. F. von Herrmann; Notes on the Climate of Kansas, by T. B. Jennings; Clayden's Cloud Studies; Weather Bureau Men as Educators; and T. S. Outram, deceased.

Meteorological observations, J. E. OSTRANDER and T. A. BARRY (*Musachusetts Sta. Met. Buls.* 217, 218, pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during January and February, 1907. The data are briefly discussed in a general note on the weather of each month.

Meteorological observations at the Michigan Agricultural College for the year 1905 (*Michigan Sta. Rpt.* 1906, pp. 117-130).—Tabulated daily and monthly summaries are given of observations during 1905 on temperature, pressure, precipitation, humidity, cloudiness, wind movement, etc.

Meteorological records for 1905 (*New York State Sta. Rpt.* 1905, pp. 385-391).—Tables are given which show the average monthly precipitation since 1882; average monthly temperature since 1882; tridaily readings of the standard air thermometer during each month of 1905; a monthly summary of maximum, minimum, and standard thermometer readings; and daily readings of maximum and minimum thermometers at 5 p. m. for each month of the year.

Meteorological summary for Bern, Switzerland, for the period 1894 to 1905 (*Mitt. Bern. Statist. Bur.*, 1906, No. 1, pp. 77-84).—A summary is given of observations on temperature, precipitation, and relative humidity at Zurich and Bern for the period 1894 to 1905, and summaries of observations on pressure, temperature, precipitation, and cloudiness during 1904 and 1905 at Beatenberg.

Observations at the meteorological observatory of the University of Innsbruck, 1903-4, W. TRABERT (*Beobachtungen des meteorologischen Observatoriums der Universität Innsbruck in den Jahren 1903 und 1904*. Innsbruck: University, 1906, pp. 133).—Detailed data for monthly, daily, and hourly observations on pressure, temperature, humidity, precipitation, sunshine, etc., are reported in tabular form.

Meteorological observations at Verona in 1905, G. FRACASTORO (*Atti e Mem. Accad. Agr. [etc.] Verona*, 5. ser., 5 (1906), Sup., pp. 51).—Observations on temperature, pressure, precipitation, humidity, direction of wind, etc., at the meteorological observatory of the Technical Institute of Verona are summarized in detail.

Influence of the ocean on climate (*Amer. Mo. Rev. of Reviews*, 35 (1907), No. 3, pp. 376, 377).—The cause and the influence on climate of the Gulf Stream and associated currents are discussed mainly on the basis of a contribution to the subject by W. Meinardus,^a it being asserted that the Gulf Stream, which to such a large extent controls the climate of Europe, is set in motion chiefly

^a Met. Ztschr., 22 (1905), p. 398.

by the winds that regularly blow from the west, and that these winds are themselves the result of regularly recurring low pressures in the region of Iceland. It is also explained that the more rapid this movement the stronger is the current of the cold stream which comes down along the northeast coast of North America.

The general conditions and their resultant effects are thus summarized: "A. (1) Feeble Atlantic circulation, from August to February, corresponds with (2) a low water temperature along the west coast of Europe from November to April, and with (3) a low atmospheric temperature in central Europe from February to April. (4) One result of this is bad harvests of grain in north-western Europe. At the same time there is (5) a great diminution of ice about Newfoundland during the spring and (6) an increased amount of ice in the region of Iceland. B. (1) Strong Atlantic circulation from August to February produces (2) a high water temperature along the coast of Europe from November to April and (3) high atmospheric temperature in central Europe from February to April. One result of this again is that (4) the weather is favorable for the raising of grain and that good harvests may consequently be expected. At the same time with this condition (5) there is much drift ice during the spring in the neighborhood of Newfoundland and (6) much less ice during the same season in the region of Iceland."

Salton Sea and the rainfall of the Southwest, A. J. HENRY (*Mo. Weather Rev.*, 3 $\frac{1}{2}$ (1906), No. 12, pp. 557-559).—An attempt is made in this article to show that there is no relation between the heavy rainfall of the last two years in Arizona and the Rocky Mountain States and the formation of the Salton Sea.

"The amount of vapor taken into the air over Salton Sea must be considerable in the course of a year, but to adduce definite and satisfactory proof that it has increased the rainfall is a very difficult problem. That it has increased the relative humidity in a slight measure, is undoubtedly true. Aqueous vapor in the absence of a strong wind circulation is diffused very slowly throughout the atmosphere. It is, therefore, improbable that any considerable portion of the local supply of vapor ever passes beyond the immediate confines of the desert."

Rainfall [in Bombay], P. J. MEAD (*Season and Crop Rpt. Bombay, 1905-6*, pp. 1- $\frac{1}{2}$, I-XVII).—Detailed data of rainfall during 1905 in the different districts of Bombay are reported and the general character of the season is discussed.

Composition of Barbados rainfall (*Rpt. Agr. Work, Imp. Dept. Agr. West Indies, 1903-1905*, pts. 1-2, p. 3).—The amount and composition of the monthly rainfall from December, 1903, to May, 1905, are tabulated. The total amount of rain falling in that period was 82.57 in., supplying approximately 239 lbs. of chlorin and 6.7 lbs. of nitrogen per acre.

Amount of chlorin in rain water, W. P. JORISSEN (*Chem. Weekbl.*, 3 (1906), pp. 647-649; *abs. in Chem. Centbl.*, 1906, II, No. 20, p. 1579; *Jour. Chem. Soc. [London]*, 92 (1907), No. 531, II, p. 48).—The average chlorin content of 154 samples of rain water was 32.5 mg. per liter.

Amount and composition of drainage waters, rain, dew, and canal water collected during the years 1903-4, 1904-5, 1905-6, J. M. HAYMAN (*Rpt. Calcutta [India] Agr. Sta.*, 1906, pp. 23-29).—Data are given for the amount and composition of water from rain and drain gages similar to those at Rothamsted, as well as for dew collected on a surface of $\frac{1}{1000}$ acre and of irrigation water used at the station during 18 months.

The rainfall during the year ended May 31, 1905, was 49.2 in., containing 0.5 part per million or 2.44 lbs. per acre of nitrogen as ammonia and 0.3 part or

0.76 lb. per acre of nitrogen as nitrates. The drainage during the same time from bare drain gages was as follows:

The quantity and composition of drainage water.

	Percolation.	Nitrogen as ammonia.		Nitrogen as nitrates.		Total nitrogen.
		Parts per million.	Pounds per acre.	Parts per million.	Pounds per acre.	Pounds per acre.
June 1, 1904, to May 31, 1905:	<i>Inches.</i>					
Six-foot gage	21.78	0.38	0.31	7.80	106.47	106.78
Three-foot gage	22.57	.19	.31	6.20	56.71	57.01
Do	8.34	.30	.35	1.70	10.87	11.22
June 1 to October 15, 1905:						
Six-foot gage	3.14	9.40	7.40	7.40
Three-foot gage	2.93	21.73	17.85	17.85
Do	3.57	22.56	23.66	23.66

During the period September 16, 1904, to March 15, 1905, the total dewfall on a surface of $\frac{1}{1000}$ acre was 0.17 in., containing 1.85 parts per million or 0.08 lb. per acre of nitrogen as ammonia and 1.72 parts per million or 0.06 lb. per acre of nitrogen as nitrates. The irrigation water used contained on the average 0.21 part per million of nitrogen as ammonia and 0.13 part per million of nitrogen as nitrates.

Nitrogenous compounds and silica in sea water, W. E. RINGER (*Chem. Weekbl.*, 3 (1906), pp. 585-608; *abs. in Chem. Centbl.*, 1906, II, No. 18, p. 1459; *Jour. Chem. Soc.* [London], 92 (1907), No. 531, II, p. 55).—It is recommended that samples of sea water be examined without delay by Raben's process, as follows: Distil 100 cc. of water with a few drops of acetic acid and examine the distillate colorimetrically for nitrous acid by the phenylenediamin test. Add 1 gm. of magnesium oxid, distil off free ammonia, and determine by the Nessler test. Reduce nitrates in the residue with aluminum foil and sodium amalgam and Nesslerize the ammonia formed. Determine silica by evaporating 3 liters of the water with hydrochloric acid in a platinum dish and taking up the residue with dilute acid.

Samples of water may be preserved by adding 1 per cent of mercuric chlorid.

The drinking waters of Vermont, G. H. PERKINS (*Rpt. State Geol. Vt.*, 1905-6, pp. 254-342).—Analyses of a number of samples of water, including some from Lake Champlain, are reported. The results show that Vermont is well supplied with good waters largely derived from springs.

Flowing wells and municipal water supplies of the Southern Peninsula of Michigan, F. LEVERETT ET AL. (*U. S. Geol. Survey, Water-Supply and Irrig. Papers Nos.* 182, pp. XI+292, pls. 5, figs. 44; 183, pp. XIV+393, pls. 5, figs. 69).—These bulletins record data obtained in examinations of several hundred flowing well districts and municipal and institutional water supplies in the State, and discuss the quality of the water supply of the Southern Peninsula of Michigan and the means of improving it.

The geology of Connecticut in relation to its water supply, H. E. GREGORY (*Ann. Rpt. Conn. Bd. Agr.*, 39 (1905), pp. 283-297).—The sources, amount, and distribution of the river, lake, and ground waters of Connecticut are briefly discussed. It is shown that while the State is in general well watered there are few farms* in it which would not give greater yields of hay and grain crops if the amount of available water were increased. It is predicted that in time irrigation will be generally practiced in Connecticut. "There is abundant water in rivers and lakes for the purpose; it needs only to be differently distributed."

Geology and underground water resources of northern Louisiana and southern Arkansas, A. C. VEATCH (*U. S. Geol. Survey, Prof. Paper No. 46, pp. 422, pls. 51, figs. 33*).—"The present report is based on the field work of the fall and winter of 1902 and 1903, supplemented by several years' field work with the Geological Survey of Louisiana and private work in eastern Texas. It covers southern Arkansas and northern Louisiana and small portions of adjacent areas in Mississippi and Texas."

The report contains six chapters, which are briefly outlined as follows:

(1) Geology, containing a discussion of the geologic history and topographic development, and including a comprehensive statement of the manner in which this portion of the coastal plain was formed and of the broader geologic facts on which the conclusions embodied in the succeeding chapters are based.

(2) General underground water conditions, containing a discussion of the fundamental principles governing underground waters and of their application to this region.

(3) Methods and cost of well making.

(4) Underground water prospects, by counties, giving well predictions and a short discussion of the underground conditions in each county.

(5) Detailed well and spring records, containing data in regard to wells, arranged in tables, by counties, with notes giving sections, etc., being, in fact, an alphabetical arrangement of all the well data collected.

(6) Dictionary of altitudes, containing a comprehensive dictionary, arranged by counties, and based on the precise levels of the United States Engineers, United States Coast and Geodetic Survey, and United States Geological Survey. To this net of precise levels the railroad levels have been connected and the corrections determined.

Geology and underground waters of the Arkansas Valley in eastern Colorado, N. H. DARTON (*U. S. Geol. Survey, Prof. Paper No. 52, pp. 90, pls. 28, figs. 2*).—This report deals briefly with the general geology of eastern Colorado and in detail with the geology and underground waters of the Arkansas Valley region.

The principal water-bearing formation of this region is the "Dakota" sandstone, but waters also occur extensively in the alluvial deposits along the valleys, in the sands and gravels mantling parts of the upland east of the mountains, and in the sandstones of the Fox Hills, Laramie, and overlying formations. Smaller amounts, mostly of bad quality, occur in the "Red Beds."

The quantity of water available from the "Dakota" sandstone in eastern Colorado is variable, and in portions of the region has been found inadequate. As a rule the pressure is too low to sustain a vigorous flow. The largest volume of water has been obtained from wells at Rockyford. In some districts the quality of the water is satisfactory, in others the waters are highly charged with minerals.

The bacterial examination of water supplies, W. G. SAVAGE (*London: H. K. Lewis, 1906, pp. XVI+297, figs. 13*).—The author of this treatise states his purpose to be to present "a book dealing, not merely with the details of practical procedure, but also with the data upon which these methods are based, and with the deductions held to be justifiable from them. . . . Dogmatic opinion has been avoided, the subject being considered from a critical standpoint, and practical conclusions drawn only when they seem justified by the available evidence."

With the advantage of a rather wide experience in the practical work of examining water supplies, he has succeeded in bringing into ordered relationship within the limits of one compact volume the more important of the large amount

of data on the subject of water examination which have accumulated during comparatively recent years.

Different chapters treat of the influences affecting bacteria in water; the quantitative bacterial content of natural waters; bacteriology of excreta, sewage, and soil in relation to bacteriological examination of water; *Bacillus coli*, *B. enteritidis sporogenes*, Streptococci, and allied organisms of water; bacterial indicators of pollution; interpretation of results of bacteriological examination of water; classification of water bacteria; collection and transmission of samples; methods for the enumeration and identification of *B. coli* and allied organisms; and examination of water for the typhoid bacillus and other intestinal organisms.

An appendix gives a summary of procedure for routine examination and describes and explains the use of a number of indicators. A bibliography of 239 references to the recent literature of the subject is also given.

SOILS—FERTILIZERS.

Soil studies, I. A. W. BLAIR (*Florida Sta. Bul.* 87, pp. 15-46, figs. 2).—Information regarding the soils of Florida is summarized mainly from publications of the Bureau of Soils of this Department and of the Florida Experiment Station. The principal facts brought out are briefly stated as follows:

"(1) Most Florida soils are very deficient in plant food, and also in those materials which, in clay soils, absorb or hold for the future use of the plant the food that is applied in the form of fertilizers.

"(2) On account of the almost entire absence of these binding materials, the loss of soluble fertilizers, by leaching, is very great; the loss from this cause on the pineapple fields of the east coast being apparently over 60 per cent of the amount applied.

"(3) These same Florida soils, however, under careful cultivation and liberal fertilizing produce abundant crops of the fruits, vegetables, and grains that are adapted to this climate.

"(4) In order, therefore, that his operations may be profitable, it is incumbent upon the Florida farmer and fruit grower to pursue such methods of cultivation and fertilizer application as will, so far as possible, prevent this loss."

The rotation of crops supplemented by application of fertilizers in order to maintain the balance of fertility is explained, as well as the use of lime, windbreaks, shading, barnyard manure and green manures, etc., to improve the chemical and physical properties of the soils.

Soils. B. C. ASTON (*New Zeal. Dept. Agr. Ann. Rpt.*, 14 (1906), pp. 105-108).—Analyses with reference to volatile matter, total nitrogen, and available (by Dyer's method) potash and phosphoric acid of 25 samples of soils from different parts of New Zealand are reported with notes on acidity and other characteristics of the soils. A plea is also made for the organization of a soil survey similar to that conducted by this Department.

The soils of the Muganj steppe and their transformation into alkali lands by irrigation. N. TULAYKOV and P. KOSSOVICH (*Izv. Moscov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscow)*, 12 (1906), No. 2, pp. 27-255, pls. 7, figs. 6, map 1).—This is the detailed report of work of which a review by S. Sacharov was noted in E. S. R., 18, p. 426. The investigations reported were made in 1905 under the auspices of the Russian government, with a view to finding means of preventing further formation of alkali soils in the region named.

The investigations show that the soils of the region are generally poor in humus (1 to 2 per cent) and nitrogen, but rich in soluble and zeolitic substances,

calcium and magnesium carbonates, phosphoric acid (0.1 to 0.25 per cent), and potash (0.4 to 0.6 per cent). The soils vary mainly in texture and structure, these variations causing them to differ widely in their behavior toward alkali under irrigation.

Flooding is the common method of irrigation employed. A study of the effect of flooding upon the movement of alkali in soils of different physical properties led to the following conclusions: (1) Flooding of the heavy, fine-grained soils may be practiced for a long time without danger of rise of alkali, but the amount of water used should be sufficient to thoroughly saturate the whole area, and the soil should be cultivated and planted as soon as the condition of the surface soil permits. (2) To avoid rise of alkali in flooding light sandy soils the water must be supplied in abundance and rapidly and irrigation must be confined to small areas at a time. Measures must also be taken to decrease the loss of water through evaporation. (3) Thorough drainage is necessary to prevent rise of alkali in the soils of this region under irrigation.

What processes go on in fallow soils? ULRICH (*Fähling's Landw. Ztg.*, 55 (1906), No. 6, pp. 200-215; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 17 (1906), No. 17-18, p. 572).—The active physical, chemical, and bacteriological processes which go on in fallow soils are discussed.

Effects of shading on soil conditions, J. B. STEWART (*U. S. Dept. Agr., Bur. Soils Bul.*, 39, pp. 19, pls. 4, figs. 7).—This bulletin reports the results of observations on temperature, soil moisture, humidity of the air, and wind movement inside and outside of a shelter tent for tobacco during the period from June 13 to August 1, 1905, and the results are discussed with reference to the influence of the conditions inside the tent on the growth of tobacco. The studies are of the same general nature as those recently reported by the Pennsylvania Station (*E. S. R.*, 18, p. 211). The main results are summarized in the following table:

Temperature, soil moisture, and relative humidity, inside and outside of tent.

Observations.	Average soil moisture for season.	Average temperature for season.	Average relative humidity for season.
	<i>Per cent.</i>	<i>Degrees F.</i>	<i>Per cent.</i>
Inside of tent.....	14.7	72.8	79.0
Outside of tent.....	11.6	71.4	71.7
Difference.....	3.1	1.4	7.3

The following conclusions are drawn:

"(1) The soil retains more moisture, which is of especial importance during the dry periods. The inside soil is then always closer to the optimum water content. Because the soil is not subject to the packing due to alternate wetting and drying, it remains in better physical condition.

"(2) The temperature of the atmosphere is made slightly warmer, which brings the temperature closer to the optimum growing temperature. An even greater effect is, however, perhaps due to the fact that there is less variation in the temperature, which is generally recognized to be of much importance.

"(3) The relative humidity of the atmosphere is greatly increased. In addition to its effect on soil and atmospheric conditions it has an influence on plant growth. . . .

"(4) The velocity of the wind is much reduced, which decreases evaporation, and is of importance in the preservation of the plants, for they are not whipped, bruised, or blown down.

"(5) The plants make a larger, more rapid, and earlier growth. These are the results that induce and make it profitable for the tiller of the soil to go to the expense of erecting the tent."

Studies on the movement of soil moisture, E. BUCKINGHAM and F. K. CAMERON (*U. S. Dept. Agr., Bur. Soils Bul. 38, pp. 61, figs. 23*).—The studies reported in this bulletin dealt with the loss of soil moisture by direct evaporation from points below the surface, especially as related to the drying of soils under arid and humid conditions, and with a general examination of the theory of capillary action in soils. The measurements of evaporation were made with soils in tumblers or small cylinders under varying conditions of moisture content, compactness, or surface tilth. The examination of the theory of capillary action in the soil was based upon curves representing the distribution by capillarity of moisture in soil in tubes under different conditions of tilth, etc.

The results in general show that, contrary to the general belief, "the loss of water by evaporation from points below the surface, while it does take place in measurable quantities, is nevertheless quite small, and is negligible in comparison with the losses taking place at or very near the surface. The movement of water vapor through the soil is shown to follow the law governing the diffusion of other gases through porous media, and is quite slow. Mulching decreases or inhibits the capillary flow, and diffusion through the mulch is practically negligible. This practice is very effective in conserving soil moisture, and is founded on sound scientific principles. An especially interesting illustration is brought out in the comparison of the loss of water from a soil under arid and humid conditions, respectively. As might be expected, the loss at first is much more rapid under the arid conditions, so rapid in fact as to overtax the soil's ability to move water from within to the surface by capillarity, and in consequence a dry layer or mulch is formed which keeps the subsequent losses far below those which take place from the soil under humid conditions, where the capillary flow to the surface persists until the moisture content of the whole soil is very low indeed. These laboratory experiments, therefore, clear up in a very satisfactory manner the well-known and apparently contradictory facts observed in the field that the soils of arid regions, at depths a little below the surface, are generally wetter and hold their moisture for much longer periods than do the soils of humid areas in dry seasons.

"An examination of the curves representing the distribution of moisture in the soil has suggested that, if the subject be regarded from the standpoint of dynamical equilibria phenomena, there appear certain analogies to the theory of electrical and thermal potential. This is a fact of great importance in the theoretical study of the subject, since we are in possession of a well-developed theory of electrical and thermal potential which can be applied to a considerable extent to the phenomena of soil moisture; it is of probable practical value, because it suggests and gives direction to further experiments and serves as a basis for the correlation of a large number of observations already made, but having hitherto a local rather than a general value.

"It is clearly recognized that the analogy is imperfect in that the capillary potential and resistance to flow are dependent upon the moisture content of the soil, whereas electrical and thermal resistance are practically independent of the amount of current and heat passing."

Quality of commercial cultures for legumes in 1906, M. J. PRUCHA and H. A. HARDING (*New York State Sta. Bul. 282, pp. 269-279*).—This bulletin reviews the results of experiments by 16 experiment stations in the United States during 1904-5 and reports a continuation of tests of commercial cultures during 1906 at the New York State Station. It is stated that the tests made by

the 16 stations have shown the commercial culture of legume bacteria dried on cotton to be of little or no practical value. The tests made by the New York State Station indicate that the metal containers which have recently been used for protecting the commercial cultures from deterioration are not effective for that purpose.

"The results from the examinations of 20 commercial cultures indicate that the goods upon the market for 1906 were little if any better than those offered in 1905. In neither year was there any evidence that the purchaser had had more than the remotest chance of receiving the worth of his money from the use of such cultures."

Dried cultures for legumes unsatisfactory, F. H. HALL ET AL. (*New York State Sta. Bul.* 282, *popular ed.*, pp. 4).—A popular edition of the above.

Principles and maintenance of soil fertility, A. R. WHITSON and C. W. STODART (*Wisconsin Sta. Bul.* 139, pp. 28, *figs.* 9).—"This bulletin is written for the purpose of putting before the farmer a statement of our present knowledge of the factors which influence the fertility of the soil and of the relation of these factors to each other."

The following topics are discussed mainly on the basis of experimental results obtained at the Wisconsin Station: Chemical composition of soils; conditions which influence fertility, such as amount and condition of organic and inorganic matter, nitrification, nitrogen fixation, and acidity; and the nature and use of fertilizers of various kinds.

Analyses and valuations of commercial fertilizers and ground bone, J. P. STREET, V. J. CARBERRY, and P. E. BROWN (*New Jersey Stat. Bul.* 198, pp. 39).—This is the final report on fertilizer inspection for the year 1906 (for previous report see E. S. R., 18, p. 433), and discusses the results of inspection for the year as a whole. Of the 635 samples of fertilizers and fertilizing materials examined during the year, 430 were complete fertilizers. The average composition of the complete fertilizers was about the same as during the previous year except in the case of potash, which showed a considerable decrease. A comparison of average prices shows that the manufacturers furnished on the average during 1906 a little less plant food than in 1905 at a correspondingly reduced price per ton.

"The same apparently wide difference of opinion among manufacturers as to the requirements of special crops is quite as noticeable as in previous years. This year there are 123 different brands designated for potatoes with 55 different guarantees, 77 for vegetables and truck with 48 different guarantees, 32 for corn with 23 different guarantees, and 23 for sweet potatoes with 13 different guarantees. The guarantees in brands designated for these different crops differ quite as widely as noted in previous years; with the possible exceptions of the formula 2:8:10 for white potatoes and the same formula for sweet potatoes, there is little agreement among the manufacturers as to the crops' requirements. These wide variations in guarantee emphasize very strongly how little useful information is supplied by the name of a brand as regards its use for any special crop."

Commercial fertilizers, T. L. CALVERT and N. W. LORD (*Offic. Rpt. Sec. Ohio Bd. Agr. on Com. Fert.*, 1906, pp. 94).—This is a report of inspection of fertilizers licensed for sale in Ohio during 1906, giving guarantees and actual analyses of 615 samples.

Some facts concerning fertilizers and their use, R. HARCOURT (*Ontario Dept. Agr. Bul.* 153, pp. 16).—This is a compilation of information on the nature and use of fertilizers, including simple directions for making fertilizer experiments.

Powdered granite as fertilizer (*Amer. Fert.*, 26 (1907), No. 1, p. 9).—Recent work on this subject by this Department and earlier experiments by Maerker are briefly discussed.

Value of ant hills as a fertilizer, T. CHURCH (*Jour. Dept. Agr. West. Aust.*, 14 (1906), No. 5, pp. 392, 393).—Analyses are reported which show this material to be of very fine texture, all passing a sieve with meshes 2 mm. in diameter and of acid reaction. The phosphoric acid in the two samples examined was 0.02 and 0.03 per cent, respectively, potash 0.06 per cent in each case, lime 0.1 and 0.07 per cent, respectively, and nitrogen 0.15 and 0.18 per cent, respectively. Very small proportions of the phosphoric acid (0.008 and 0.005 per cent) and potash (0.02 and 0.01 per cent) were available. Experiments with the soil with different crops indicated that it was somewhat more fertile than soil surrounding the ant hills.

Origin, occurrence, and chemical composition of peat, W. E. McCOURT (*Sci. Amer. Supp.*, 63 (1907), No. 1622, pp. 25994, 25995).—In this article, abstracted from the annual report of the State geologist of New Jersey, analyses of peat of various kinds are compiled from different sources and the characteristics of the different kinds of peat are described.

The technology and uses of peat, C. W. PARMELEE (*Ann. Rpt. State Geol. N. J.*, 1905, pp. 232-256; *Sci. Amer. Supp.*, 63 (1907), Nos. 1626, pp. 26046, 26047; 1627, pp. 26062, 26063; 1628, pp. 26086, 26087).—This is one of a series of articles on this subject and deals especially with the uses of peat as fuel, in agriculture as a filler for fertilizers and as litter and in composts, for manufacture of textiles as absorbent, non-conductor of heat and sound, as a preservative, etc.

On the fertilizing value of the residue obtained from the retting of hemp, G. A. CALABRESI (*Staz. Spcr. Agr. Ital.*, 39 (1906), No. 6-7, pp. 618-622).—Analyses with reference to fertilizing constituents are reported of 3 samples of this material in the wet, air-dry, and dry (at 100° C.) condition. In these analyses the percentage of moisture varies from 49.3 to 54, of nitrogen from 0.23 to 0.55, of phosphoric acid from 0.17 to 0.24, and of potash from 0.26 to 0.35. In the air-dried material the moisture varies from 10.2 to 14.1 per cent and the percentages of the other constituents increase in proportion.

Hoof meal (*Amer. Fert.*, 26 (1907), No. 1, pp. 10, 11).—The methods employed by packers in preparing this material for use as a fertilizer are briefly described.

On manures and fertilizer trials, M. WEIBULL (*Fyra Uppsatser i Växtkultur. Gothenburg*, 1906, pp. 45-69).—This is one of four articles published in the pamphlet quoted on the occasion of the twentieth general Swedish agricultural convention at Norrköping in 1906.

The story of soils and plants in their relation to liming, H. J. WHEELER (*Ann. Rpt. Conn. Bd. Agr.*, 39 (1905), pp. 74-103, figs. 15).—A rather complete review of the more practical results of investigations relating to the use of lime in agriculture.

The need of liming for heavy marsh soils, CLAUSEN (*Illus. Landw. Ztg.*, 27 (1907), No. 9, pp. 63, 64).—This article briefly reports experiments which show the beneficial effects on such soils of liming and marling. The comparative economy of the two materials is discussed, but no definite conclusion is reached on this point.

Use of different forms of lime (*Jour. Bd. Agr. [London]*, 13 (1907), No. 10, pp. 621-623).—Comparative tests by the agricultural department of the Lancashire County Council of coarse quicklime (cob lime), ground lime, and ground limestone on meadow land are reported. The results in general indicate that the more finely divided forms of lime are more immediately effective than

coarser quicklime and also that ground limestone is a more profitable dressing than either ground lime or coarse quicklime.

Investigations on the action of lime nitrogen on various kinds of soil, T. REMY (*Landw. Jahrb.*, 35 (1906), *Sup.* 4, pp. 114-133, pls. 2; *abs. in Deut. Landw. Presse*, 34 (1907), No. 6, p. 49).—A series of pot experiments on the utilization of the nitrogen of this material, its injurious action on the growth of plants, and its effect on the bacterial life of the soil is reported, from which the following conclusions are drawn:

The efficiency of this source of nitrogen depends largely upon the character of the soil upon which it is used. It is most efficient on clayey soils, being in this case but little inferior to nitrate of soda. On such soils injurious effects are not observed even when the material is applied in comparatively large amounts. Much less favorable results, however, were obtained on sandy soils. In this case the utilization of the nitrogen was much less complete and rapid than on heavy soils, comparing in these respects more nearly with blood meal. Even in amounts not exceeding the usual applications of such materials the lime nitrogen showed an injurious effect on germination and growth of plants on such soils. The injurious effect was especially marked in the case of the nitrogen-collecting bacteria (*Azotobacter*) of the soil. The length of time through which the injurious effect will continue was not definitely determined. In the experiments reported by the author the effect on germination had entirely disappeared at the end of 3 months. The results indicate in general that lime nitrogen should be used with caution on light soils.

Some experiments on the action of lime nitrogen and nitrogen lime on cultivated plants, F. MACH (*Fühlings Landw. Ztg.*, 55 (1906), No. 24, pp. 830-847).—Pot experiments extending over 4 years to test the relative fertilizing value of these materials are reported with barley, mustard, carrots, and buckwheat.

The "nitrogen lime" used was that prepared by the Polzenius process of fixing free nitrogen by passing it over a heated mixture of calcium carbide and calcium chloride. It contained about 22 per cent of nitrogen, while the lime nitrogen with which it was compared contained about 18 per cent of nitrogen.

The results showed in general that the two fertilizers were about equally effective and that the nitrogen was equally well utilized by the crop in each case. As a rule no appreciable injurious effect was observed from either source.

Experiments with nitrogen lime, B. HARDT (*Deut. Landw. Presse*, 34 (1907), No. 5, pp. 29, 30).—Cooperative tests by farmers under different conditions of soil, cropping, etc., are briefly reported.

The results were in general favorable to the use of the material as a fertilizer, especially when applied some time before planting of the crop and thoroughly incorporated with the soil. It gave good results on sandy soils when these were not acid. On old cultivated lands it gave best results when the soil had previously been well fertilized with barnyard manure. Moor soils should be well limed before the application of this material.

Nitrate of soda statistics (*Saaten, Dünger u. Futtermittel*, 1907, No. 3, p. 77).—Statistics of production and consumption of this material from 1897 to 1906 are summarized. The world's consumption during 1906 is given as 1,639,300 tons, of which 1,241,400 tons was used in Europe and 361,900 tons in the United States.

Wholesale manufacture of nitrate fertilizer, C. M. PEPPER (*Daily Consular and Trade Rpts.* [U. S.], 1907, No. 2766, pp. 3, 4).—A brief note is given referring to the prospective utilization of the Jhelum River in Kashmir, India, in the manufacture of lime niter for fertilizing purposes by the Norwegian

process. The conditions are said to be unusually favorable to such a project, namely, abundant water power and unlimited limestone near at hand. It is also close to the Punjab, the great grain-growing region of India, which is in great need of a cheap nitrogenous fertilizer.

Comparative fertilizer tests of Thomas slag and agricultural phosphate. L. PECHMANN and CLAUSEN (*Fühling's Landw. Ztg.*, 55 (1906), No. 24, pp. 855-857; *Deut. Landw. Presse*, 34 (1907), No. 3, p. 17).—The results of experiments by different investigators are briefly summarized.

On the stability of Thomas-ammonium-phosphate lime, M. SCHMOEGER and L. VON WISSELL (*Fühling's Landw. Ztg.*, 56 (1907), No. 1, pp. 1-6).—The authors found that this material as prepared by the usual process of mixing Thomas slag, ammonium sulphate, and lime waste from beet-sugar factories loses a considerable amount of its nitrogen in a comparatively short time. By adding about 5 per cent of calcium chlorid or 3 per cent of dried carnallite, this loss was entirely prevented.

Comparative fertilizer tests with Thomas slag and agricultural phosphate, BACHMANN (*Mitt. Deut. Landw. Gesell.*, 21 (1906), No. 51, pp. 483-485).—Replying to a previous article by Clausen (*E. S. R.*, 18, p. 620), the author presents further data to show that under proper conditions agricultural phosphate is a very effective fertilizer. The principal of these conditions are good mechanical condition of the soil, a sufficient supply of humus, and thorough distribution of the phosphate in the soil. The use of barnyard manure with the phosphate also increases its effectiveness, and conditions which promote the growth of bacterial flora in the soil favor assimilation of the phosphate.

Comparative fertilizer tests of agricultural phosphate and Thomas slag, CLAUSEN (*Mitt. Deut. Landw. Gesell.*, 22 (1907), No. 4, pp. 26-28).—A reply to an article by Bachmann already noted (*E. S. R.*, 18, p. 621), in which the author maintains that the use of ammonium sulphate in connection with Thomas slag and agricultural phosphate results in an over valuation of the phosphoric acid in the agricultural phosphate and under valuation of that in Thomas slag.

AGRICULTURAL BOTANY.

Distribution and adaptation of the vegetation of Texas, W. L. BRAY (*Bul. Univ. Texas, Sci. Ser.*, No. 10, pp. 112, pls. 14, figs. 4).—This bulletin was prepared by the author with the desire of presenting to teachers a point of view from which to study the vegetation of the State, which is not supplied by present publications. In the bulletin the vegetation of Texas is considered as a whole from the standpoint of its relation to environment. The various factors of plant environment and how they affect plants are described, consideration being given to water, temperature, light, atmosphere, and edaphic and biological factors. After discussing the environmental factors, the author describes the various plant societies which he recognizes as occurring in the Texas region.

The relation between the osmotic strength of cell sap in plants and their physical environment, E. and HILDA DRABBLE (*Bio-Chem. Jour.*, 2 (1907), No. 3, pp. 117-132).—In a previous publication the authors gave a preliminary statement regarding the osmotic strength of sap in plants growing under different conditions (*E. S. R.*, 18, p. 127). Their investigations have been continued, so that 48 plants have been studied from quite a range of environment, including bogs, gardens, woods, moorland and mountains, sand dunes, brackish water, and salt marshes, and the relation between environment and strength of the cell sap in the different plants has been clearly established.

The authors in summarizing their investigations show that the osmotic strength of cell sap is least in submerged fresh-water plants and greatest in

salt-marsh plants. The greater the physiological drought under which the plants are accustomed to grow the greater will be the osmotic strength of the sap in the turgid cell. For any locality the osmotic strength will vary with the physiological scarcity of water. In all plants growing under the same conditions the osmotic strength of the cell sap is practically the same. Where marked differences in structural arrangements for checking loss of water by transpiration are present the plants with the less adequate anatomical provision for transpiration will have the greater strength of cell sap. The effect of increasing the osmotic strength of sap on absorption is very marked, the rate of absorption of water being proportional to the osmotic strength of the sap. The effect of increased temperature is also quite appreciable and tends to enhance the power of absorption of water by plants.

On the transpiration current in plants, H. H. DIXON (*Proc. Roy. Soc. [London], Ser. B, 79 (1907), No. B 528, pp. 41-57, figs. 5*).—The author criticises a paper by Ewart (E. S. R., 17, p. 958), pointing out objections to the methods of investigation presented, and in addition he gives further arguments affirming the cohesion theory of Dixon and Joly regarding the transpiration current in plants (E. S. R., 7, p. 560).

The effects of magnesium sulphate upon seedlings, GERTRUDE BURLINGHAM (*Abs. in Science, n. ser., 25 (1907), No. 638, p. 452*).—A report is given of extended experiments to test the effect of dilute solutions of magnesium sulphate on seedlings. It was found that while magnesium sulphate is usually toxic in strengths greater than 0.003 per cent, in weaker solutions it produces a decided-stimulating effect, reaching a maximum in dilutions of 0.00075 to 0.00018 per cent. Beyond this point the action gradually diminishes.

Seedlings allowed to grow for several weeks in a dilute solution of magnesium sulphate which was at first slightly toxic, finally developed strong lateral roots and attained a root growth far beyond the controls. This seems to show that magnesium sulphate in proper dilution is beneficial to the growth of seedlings, and that any inhibitory effects are due to the presence of excessive amounts, thus controverting Loew's theory that magnesium salts when alone in solution are always injurious to plant growth.

The effects of salts of some rare elements on seedlings, ALICE A. KNOX and W. H. WELKER (*Abs. in Science, n. ser., 25 (1907), No. 638, p. 461*).—Salts of a number of rare elements were tested on seedlings. The greatest molecular concentration points at which growth occurred during the first 24 hours were noted, as well as the least growth. It was found that the increase in toxicity followed Mendeléeff's table almost mathematically, the toxicity increasing from group to group with the increase in molecular weight.

The physiological resistance of saline plants to the action of sea salt, A. CASU (*Ann. Bot. [Rome], 5 (1907), No. 2, pp. 273-354, figs. 2*).—A study was made of the flora of Cagliari to ascertain some of the factors which determine the distribution of plants in soils that are more or less impregnated with salt. After an extended review of literature, the author gives in detail the results of his investigation on the physical, chemical, and physiological effect of various salts on the germination and growth of the strand flora, comparing the results obtained in his experiments with the spontaneous occurrence of plants in the regions studied.

Observations on the effects of the rays of radium on plants, C. S. GAGER (*Abs. in Science, n. ser., 25 (1907), No. 638, p. 462*).—It has been shown that the rays of radium and other radioactive substances act as a stimulus to germination and growth, and further experiments by the author warrant a similar conclusion with respect to other plant activities, such as respiration, starch

making, geotropic response, etc. The growth of plants watered with radioactive water may be accelerated or retarded, the results varying not only with the degree of radioactivity but also with the species of plant employed. When pollen or ovules were exposed before pollination, or when exposure was made after fertilization of the egg, plants growing from the resulting seeds were found to vary profoundly from the parent plants. Whether these variations are capable of transmission is yet to be determined.

Composition of cocoanut water and presence of diastases in cocoanuts, E. DE KRUIJFF (*Bul. Depl. Agr. Indes Néerland., 1906, No. 4, pp. 1-8*).—In the course of a study to determine the industrial value of the so-called milk or water of the cocoanut, the author investigated its composition and also the occurrence of diastases. It was found that the cocoanuts contained saccharose, which is inverted during the maturity of the nut by a diastase secreted by the cells of the endosperm. In addition to sucrose the author reports the presence of oxydase and catalase, the two latter not being present in the immature fruit. The haustorium was found to contain in addition to these diastases lipase, amylase, catalase, and peroxydase.

The rôle of phenols, tannic acids, and oxybenzoic acids in cork formation, E. DRABBLE and M. NIERENSTEIN (*Bio-Chem. Jour., 2 (1907), No. 3, pp. 96-102, pl. 1*).—According to the authors, it is generally believed that tannins and other aromatic compounds play an important part in the lignification of wood elements, and that when tannins, phenols, and oxybenzoic acids are treated with formaldehyde and a little hydrochloric acid, condensation products are precipitated. This suggests that in the formation of cork similar condensation products probably play an important part.

The authors made an examination of a number of living plants to trace the distribution of tannic acid, phenols, etc., in the stems, and in every case where cork was found a coloration of the cells in the immediate vicinity was shown, indicating the presence of gallic or tannic acid. In the plants which gave no reaction no cork was present.

The authors are led to attribute to tannic acids, phenols, gallic acid, and other oxybenzoic acids an important rôle in the formation of cork. The presence of substances of this class was clearly shown wherever cork tissue was found. The substances giving cork reactions are precipitated from tannic acids, phenols, and oxybenzoic acids by means of formaldehyde in the presence of various acids, and products having the same mother substance as these condensation products have been obtained from the cork itself. The authors believe that tannic and gallic acids and substances of this nature are acted upon in the plant by formaldehyde and various acids and are precipitated on the walls of the cork cells.

Hydrocyanic acid glucosids and hydrocyanic acid in plants, A. EICHINGER (*Pharm. Ztg., 52 (1907), No. 15, pp. 146, 147*).—A résumé is given of considerable of the literature relating to the occurrence in plants of glucosids that under the influence of enzymes split up into hydrocyanic acid. The occurrence of these glucosids in a number of species of plants is mentioned, and the localization, source, and function of hydrocyanic acid are discussed.

On the poisons of *Amanita phalloides*, J. J. ABEL and W. W. FORD (*Jour. Biol. Chem., 2 (1907), No. 4, pp. 273-288*).—It has been shown by one of the authors that the poisons of the fungus *Amanita phalloides* belong to the group of bacterial toxins, and further that the principle described by Kobert under the name of phallin as the only poison present is accompanied by a highly toxic substance devoid of hæmolytic properties. The presence of this substance can be demonstrated by biological experiments.

The authors state that immunity can be established toward the two poisonous

principles of *A. phalloides* and that the serum of immunized animals is anti-hemolytic and antitoxic in character.

The hemolytic principle contained in *Amanita* and first detected by Kobert is not a toxalbumin, as was supposed, but a nitrogenous glucosid which is very sensitive toward the action of heat and acids and easily decomposed by acids so as to yield a pentose and some volatile base or bases, such as ammonia and methylamin. This glucosid the authors have designated as *Amanita-hemolysin*. Its properties are said to be such as to preclude it from playing any rôle as a blood poison in the case of poisoning by these mushrooms.

The influence of mushrooms on the growth of some plants, G. F. ATKINSON (*New York Cornell Sta. Bul.* 249, pp. 217-234, figs. 11).—The author carried on an investigation to determine whether the substance of various fleshy fungi could be used as food to any extent by green plants in either an undecomposed condition, or when partly or completely decomposed by bacteria or fungi.

In the spring of 1905 some preliminary experiments were conducted with the common mushroom (*Agaricus campestris*) as a source of plant food for corn, beans, peas, and buckwheat. In the winter and spring of 1906 these experiments were repeated with better control. The plants were grown in quartz sand, and the mushroom material was used fresh in an unfermented condition in some of the pots, while in others it was fermented. Wheat, buckwheat, corn, sunflower, and radishes were planted in the different pots. It was found that the stronger fermented substance produced the richest color and tallest plants, followed by the weaker strength of fermented material, while the check plants were the smallest and the poorest in color. An examination of photographs taken of the growing plants showed a constancy in the curve of growth for the different kinds of plants corresponding to the nature of the material supplied.

Experiments were also carried on with pure cultures with agar-agar as a substratum, and the results were in the main comparable with those described above.

The author states in conclusion that the experiments show that a portion of the substance of the common mushroom and probably of all the Basidiomycetes may become available as food for autotrophic green plants, and that the decomposition products of heterotrophic plants form a nearly perfect food for autotrophic ones.

The properties of culture media as affected by certain products of plant metabolism, O. SCHREINER and J. F. BREAZEALE (*Abstr. in Science, n. ser.*, 25 (1907), No. 638, p. 454).—It is claimed that certain products of plant metabolism, such as degradation products of proteids and lecithins, are harmful to seedling plants. Some of these products found in green plants lose their toxic properties on oxidation and become beneficial. It is pointed out that this explains the advantage of green manuring over mineral fertilizers.

On the chemical action of spores, J. EFFRONT (*Monit. Sci., 4. ser.*, 21 (1907), No. 782, pp. 81-87).—While studying the oxidation of albuminoids the author found that albumin coagulated at 110° C. and kept in a humid sterile atmosphere finally showed pronounced enzymic characters. An investigation of the occurrence of enzymes in sterile media and the chemical action of dead cells led him to decide that the appearance of enzymes in sterile media is due to the presence of bacterial spores which still retain their secreting power although their ability to germinate has been destroyed.

A study of the spores of *Bacillus subtilis* confirmed this conclusion. It is claimed that spores of bacteria retain their property of producing enzymes after their vitality has been destroyed by heat or otherwise. The spores of *B. subtilis* were found capable of producing large quantities of amylase and peptase. The production of enzymes by bacterial spores increases as the possibility of their

development diminishes, reaching a maximum at the time when absolute sterility is attained. The chemical changes which take place in milk, wine, beer, etc., after sterilization are to be attributed in part at least to the results of arrested spore development. The author says that the liquefying and saccharifying action which is acquired by albumin under the influence of metallic acids is to be explained by the constant presence of spores of *B. subtilis* in the albumin and not, as has been repeatedly claimed, by the appearance of artificial diastases.

FIELD CROPS.

Results obtained in 1906 from trial plats of grain, fodder corn, field roots, and potatoes, W. and C. E. SAUNDERS (*Canada Cent. Expt. Farm. Bul.* 55, pp. 35).—The results secured in 1906 in variety tests conducted at the Canada experimental farms with the different field crops are given in tabular form with brief general notes. The reports of earlier years have been previously noted (*E. S. R.*, 17, p. 961).

The testing of different varieties on uniform trial plats has now been in progress for 12 years, but this bulletin departs from previous reports in omitting the averages of the returns from all the experimental farms. The tables are so arranged as to show the varieties in the order of their average yield for the last 5 years.

Is the protein content of barley a variety characteristic? H. TEDIN (*Svenskes Utsädesför. Tidskr.*, 16 (1906), No. 4, pp. 177-187).—The results of protein determinations in Swedish malting barley secured from 1899 to 1904 showed variations ranging generally from 2 to 4 per cent in all the varieties analyzed. Some samples of each variety tested were found to contain over 11 per cent of protein. The maximum content, 15.14 per cent, was obtained in a sample of Svanehals, and the minimum, 7.23 per cent, in a sample of Princess. On an average Princess contained about 1 per cent less protein than Chevalier.

The author concludes that the variety is of minor importance in determining the protein content of barley, and that this factor depends mainly upon conditions of culture and growth.—F. W. WOLL.

Corn culture, R. J. REDDING and J. M. KIMBROUGH (*Georgia Sta. Bul.* 74, pp. 195-208).—The 10 varieties compared during the season of 1906 gave an average yield of 25.13 bu., Marlboro Prolific and Coker Prolific leading with 28.60 and 28.50 bu. per acre, respectively. Marlboro stood second in 1905. Hastings' Prolific, which made the smallest ears, ranked sixth this year, while Marlboro, which gave the third smallest ears, stood first. Henry Grady, making the largest ears, ranked fifth in the total yield of shelled corn per acre. From these results it appears "that there seems to be no very significant relation between the total yield and the size of the ears."

A comparison of cotton-seed meal and crushed cotton seed as a fertilizer for corn resulted in a yield of 24.56 bu. per acre on the cotton-seed meal plats and of 22.95 bu. on the crushed cotton-seed plats. Cotton-seed hulls were found not only ineffective as a means of increasing the yield of corn in the current year, but even actually reduced it. This material is considered too valuable as cattle feed to be used as a fertilizer. As in former years dividing the applications either of cotton-seed meal or nitrate of soda, applying one-half before planting and the rest as late as either May 1 or May 20 was found inexpedient.

Brief notes on corn culture based on the results secured in 17 years of experiments conclude the bulletin.

Williamson method of corn culture, J. F. DUGGAR and L. N. DUNCAN (*Alabama Col. Sta. Bul.* 138, pp. 102-106, figs. 2).—A comparison is reported of the Williamson and ordinary methods of growing corn. A plat was devoted to each

method and the treatment was identical except in the points which distinguish the Williamson method.

The yield of shelled corn was 30.5 bu. per acre on the Williamson plat and 29.5 bu. on the check plat. On the Williamson plat each plant averaged 0.346 lb. of shelled corn and on the other 0.667 lb. The average weight of ear on the check plat was 0.54 lb. as compared with 0.45 lb. on the Williamson plat. One hundred plants grown by the Williamson method produced 96 ears and nibbins as compared with 156 ears and nibbins in the check test. The average height from the ground at which the ears grew on the check plat was 44½ in. and on the Williamson plat 36½ in. The Williamson plat showed 29 per cent of broken stalks while the check plat showed only 14 per cent.

Applications of 200 lbs. cotton-seed meal, 200 lbs. acid phosphate, 400 lbs. kainit, and 200 lbs. nitrate of soda per acre were used, but the yield was not sufficient to make the use of such large quantities of fertilizers profitable. It is believed that the proportion of kainit in the Williamson fertilizer is too high.

It is also suggested that the unusually large yields obtained by this method on upland in South Carolina may be due more to the frequent plowing under of a crop of cowpea vines, to the liberal use of nitrogenous fertilizers, and to close planting than to the dwarfing of the plants through omission of cultivation and withholding until late the application of fertilizers.

Variety tests with cotton and corn, J. F. DUGGAR and L. N. DUNCAN (*Alabama Col. Sta. Bul. 138, pp. 97-102*).—Of 32 varieties of cotton under test Toole, Cook Improved, Cleveland, Bancroft, Herlong, and Christopher ranked first in 1905, and of 20 varieties compared Cook Improved, Cleveland, Layton, Toole, and Pullnot were the leaders in 1906. Sunflower and Floradora, which were grown in this experiment, are long staple varieties and commanded in the home market a premium of about 4 cts. per pound.

In 1905, estimating the lint at 11½ cts. per pound and the seed at 7 cts. per 100 lbs., the total value per acre ranged from \$20.64 to \$67.94, and in 1906, the lint being regarded as worth only 10 cts. per pound, the total acre value varied from \$45.91 to \$69.30.

The leading varieties of corn in a list of 18 and their yields were as follows: Sanders 28.9 bu. per acre, Marlboro 28.3 bu., Mosby 26.0 bu., and Henry Grady 25.7 bu. Sanders, Marlboro, and Mosby are several-eared sorts. Early northern varieties were again shown to be worthless for Alabama.

Cotton culture, R. J. REDDING and J. M. KIMBROUGH (*Georgia Sta. Bul. 75, pp. 211-240*).—Twenty-six varieties of cotton were under test. In value of total products per acre the leading varieties, given in decreasing order, were as follows: Layton Improved, Cleveland Big Bell, Broadwell Double-Jointed, Cook Improved. These varieties all produced values of over \$65 per acre. The average total value of lint and seed produced by the 26 varieties was \$60.01 per acre, the range being from \$47.15 to \$75.59 per acre. The average yield of seed cotton per acre was 1,517 lbs., and the range 1,315 to 1,754 lbs.

The average results of this work for 13 years show that the best half of the number of varieties grown each year produced 34.9 per cent of lint and the others 32.5 per cent. In 1906 the best half of the varieties grown produced 36.8 per cent of lint as compared with 37.8 for 1905. The best yielding varieties also showed the larger size of bolls, although in some years there were exceptions to this rule. Earliness was in favor of the better yielding sorts during 4 seasons and in favor of the poorer yielders the remaining 9 years.

A high percentage yield of lint appears very closely related to a high value of total products. The size of the bolls is to be considered in relation to the cost of picking.

It was found that a fertilizer application, of which the nitrogenous ingredient

consists of cotton-seed meal, is most effective when bedded on from 7 to 16 days in advance of planting.

Cross planting cotton with corn was not found profitable. It was also shown that the use of sound cotton seed directly as a fertilizer or a fertilizer ingredient is a very unwise practice.

Applications of 400, 800, and 1,200 lbs. of a fertilizer consisting of 1,000 lbs. of 17 per cent acid phosphate, 498 lbs. cotton-seed meal, and 74 lbs. muriate of potash were compared. The plats receiving 400 lbs. at a cost of \$4 produced 281 lbs. of seed cotton more per acre than the unfertilized plats. The use of 800 lbs. increased the yield over the check plats by 436 lbs., and the use of 1,200 lbs. showed an increase of 588 lbs. of seed cotton. Cotton hulls as a fertilizer did not prove profitable.

In a condensed review of the results of 17 years of cotton culture it is pointed out that plowing from 6 to 8 in. deep and thoroughly harrowing the land is more effective than deeper but less careful breaking and fining of the soil. Subsoiling has not been found advisable on the upland soils of middle Georgia. The results of the variety tests seem to favor a variety with large bolls, large seed, high percentage of lint, medium earliness, and persistent fruiting capacity. On land capable of yielding $\frac{3}{4}$ to $1\frac{1}{2}$ bales per acre the rows are recommended to be $3\frac{1}{2}$ to 4 ft. wide, with the plants 12 to 18 in. apart in the drills.

With regard to commercial fertilizers it is stated that these should be applied and bedded on not less than a week before planting, and that it does not pay to divide the amount into 2 or more applications, although nitrate of soda may sometimes be applied with profit a month or more after planting. As a general rule shallow cultivation once a week and once in a row is advised. The rotation of crops laid down consists of small grain followed by cowpeas the first year, cotton followed by rye or vetch the second year, and corn and peas the third year.

An interesting cross between a variety of emmer and spelt, P. H. STOLL (*Deut. Landw. Presse*, 34 (1907), No. 13, p. 100, figs. 2).—Reciprocal crosses were made between a hairy, bearded winter emmer and Stoll brown winter spelt, itself a cross between Main standup wheat and red winter spelt. The use of emmer as the male parent resulted in 5 poorly developed kernels which failed to germinate, while the use of spelt as the male parent gave a single grain which germinated vigorously and survived the winter in the open. The plant from this seed showed the beardless character of the spelt and the hairiness of the emmer. In form of spike and strength of stem it resembled spelt. The author considers beardless heads and hairy glumes as dominant and bearded heads and smooth glumes as recessive characters. The second generation was characterized by multiplicity of forms.

Flax culture, W. L. MARCY (*U. S. Dept. Agr., Farmers' Bul.* 274, pp. 36, figs. 11).—This bulletin is an extract from a report on this subject published by the North Dakota Station as Bulletin 71, which has already been noted (*E. S. R.*, 18, p. 632).

Flax experiments, 1905 (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 7 (1907), No. 2, pp. 250-268).—The results of this year's fertilizer experiments confirm the conclusion of previous years that a potassic manure either in the form of kainit, muriate of potash, or sulphate of potash is generally profitable when applied to the flax crop, and that such treatment effectually prevents yellowing. A comparison of seed from different sources showed the net returns per acre from home-saved seed to be inferior to Dutch seed and Kostroma seed imported from Russia, but better than those yielded by the Belfast brand of Riga seed.

As in previous years scutching tests were made to determine the comparative

effectiveness of Irish and Belgian mills and Irish and Belgian workers. A heavier yield of scutched flax was produced in the Irish mill, but the product was of much poorer quality than the flax worked on a modified Belgian mill. The test further indicated that better results could be produced by Irish workers in mills of a somewhat lighter type than those generally used in Ireland. It is believed that for well retted straw a mill with a large number of light blades, even as many as 12 on the round, is the most satisfactory.

Rippled straw gave a slightly better yield of scutched flax than unrippled straw. Rippling gave a financial balance of 6s. 9d. per ton of green straw in its favor. The practice is recommended particularly for crops which have produced a large quantity of seed.

Half a ton of Irish grown and dried straw was retted by each of the 3 Belgian systems and by the Irish system for comparison. The home system proved the best as, while the quality of the flax yielded by the straw retted twice in the River Lys was highest, the increase in cost rendered the net returns lower than those from straw steeped in Ulster.

Investigation on correlation in fodder beets, H. MAAS (*Landw. Jahrb.*, 35 (1906), No. 4, pp. 84-113).—The method of carrying on this investigation is described and the data secured are given in tables.

The results show that the percentage of sugar within the variety decreased as the weight of the beet increased, but the rate of increase was not the same so that the total quantity of sugar was more dependent upon the quantity than upon the quality of the beet. Dry matter and sugar content increased regularly together in different varieties as well as within the same variety, but this correlation is not regarded as a reliable measure of either the dry matter or the sugar content in individual beets, or of the average of these substances in a number of them. The percentage of sugar in the beet increased with the percentage of sugar in the dry matter. The sugar content of the dry matter was found to be about 50 per cent when the fresh beet contained from 4.8 to 5 per cent.

Beets low in leaf area were characterized by a high content of dextrose. No correlation was apparent between the content of ash, nitrogen, crude fiber, and fat and the dry matter or the sugar content of the beet. In comparing varieties it was found that these substances in connection with an increase in sugar decrease in the dry matter, while they increase in the fresh beet. The quantity of foliage increased with the quantity of the roots. It is stated that the percentage relation of foliage and roots is determined largely by the season, the percentage weight of foliage decreasing with the weight of the root in dry seasons and increasing with the same in years of greater rainfall. The author considers the leaf area as a regulator of transpiration of high importance in the fodder beet. While leaf area and leaf quantity are connected, there is no close correlation between these 2 factors. Close planting produced a thinner leaf but a stronger leaf stem than wide planting. No connection between leaf thickness and sugar content could be determined.

Native forage plants and their chemical composition, N. E. WILSON, S. C. DINSMORE, and P. B. KENNEDY (*Nevada Sta. Bul.* 62, pp. 41, pls. 13, figs. 9).—This bulletin presents the results of a chemical study of 12 species of grasses and 14 species of herbaceous plants, conducted with a view to determine the quality of the various plants for forage. Each species is described and its analysis given in a table.

Farm practice with forage crops in western Oregon and western Washington, B. HUNTER (*Oregon Sta. Bul.* 91, pp. 40, figs. 4).—This bulletin is identical with bulletin 94 of the Bureau of Plant Industry (E. S. R., 18, p. 229).

Loss in weight of stored potatoes, DENAÏFFE (*Jardin*, 21 (1907), No. 481, pp. 76-79, figs. 2).—The results of observations made show that the loss in weight during storage varies with the variety and is not the same for all months. Of the varieties studied the loss was about 1 per cent per month, or about 7 per cent from the time of harvesting until June 1. The loss was greatest in the varieties grown for the table, especially in the early sorts, and less in the potatoes grown for forage or industrial purposes. The early table varieties lost about 8 per cent during the storage period, while the other sorts lost only about 5½ per cent.

Results of culture experiments in 1906 at the German potato experiment station (*Deut. Landw. Presse*, 34 (1907), No. 13, pp. 100-102).—Twenty varieties under test gave an average yield of 24,770 kg. of tubers and 4,460 kg. of starch per hectare, the average starch content being 17.9 per cent. The variety Professor Wohltmann ranked first in yield of tubers with 29,560 kg., and also first in yield of starch with 5,810 kg. per hectare. Brocken stood highest in starch content with 20.5 per cent.

Results of F. Heine's potato culture experiments in 1906 (*Deut. Landw. Presse*, 34 (1907), No. 14, pp. 109-111).—Of 99 varieties tested, Hildesia, Eduna, and Sas ranked first in yield. Fürst Bismarck, which stood fifth in yield, ranked first in yield of starch and starch content. Notes on different varieties with reference to their suitability for culinary and industrial purposes are also given.

Rice culture, R. J. NELSON (*Arkansas Sta. Bul.* 94, pp. 31-45).—It is stated that the acreage of rice in Arkansas increased from 450 acres in 1905 to about 5,000 acres in 1906. At the station rice was sown at the rate of 1¼ to 1½ bu. per acre on different dates from April 20 to May 16. The earliest sowing produced the maximum yield, 77.76 bu. per acre. The irrigation period of this crop was 84 days. The Honduras variety produced at the rate of 61.84 bu. and the Japan, 52.44 bu. of rice per acre, the average being 57.5 bu.

Notes are given on the history and food value of rice, together with directions for rice culture in general.

Sugar beet growing experiments in England, Scotland, and Ireland, 1906 (*Internat. Sugar Jour.*, 9 (1907), No. 98, pp. 84-91).—The analyses of 157 samples of sugar beets are given in tables. The average sugar content of the samples was 15.46 per cent. The juice constituted 93.12 per cent and the pulp 6.88 per cent of the beets.

Injurious effect of nitrogen in the sugar beet, K. ANDRĚK (*Ztschr. Zuckcrindus. Böhmen*, 31 (1907), No. 5, pp. 277-284).—The results of experiments show that the presence of nitrogen in the beet may reduce the quality of the juice and be detrimental to the manufacture of sugar. The quantity of injurious nitrogen found in the root varied with the kind of seed. The use of a single nitrogenous fertilizer, whether in the form of nitrate or ammonia, increased the quantity of nitrogen in the beet, but the use of barnyard manure up to about 27 tons per acre under conditions of a normal rainfall produced no injurious effect. When a heavy application of nitrate of soda up to about 1,000 lbs. per acre is made the injurious effect may be largely reduced by the addition of potash and superphosphate.

Experimental work in the production of table sirup at Waycross, Ga., 1905, H. W. WILEY (*U. S. Dept. Agr., Bur. Chem., Bul.* 103, pp. 38).—The plan of the fertilizer experiments with sugar cane here reported has been previously described (*E. S. R.*, 17, p. 458). The results for 1905, the last year of the work, are given in this bulletin together with a summary of the entire 4-year experiment.

In 1905 the fertilizer experiments were conducted at Cairo, Ga., on 2 fields, A and B. Field A, a good grade of pine land, had been in cultivation for at least 20 years, and field B, of the same grade of land, only about 6 years. The plats receiving no fertilizers produced an average of 11.07 and 14.52 tons of cane per acre on fields A and B, respectively. The highest average yields, 23.41 tons on field A and 25.84 tons on field B, were secured on the plats receiving either 1,200 or 2,000 lbs. of the normal formula in two applications.

Canes grown below the frost line in Florida were analyzed and found to be very rich. Samples received March 31 contained 20.90 per cent of sucrose, and samples received from the same locality November 11, 13.50 per cent, the purity for the 2 lots being 91.30 per cent and 79 per cent, respectively.

Grinding cane was begun at the experimental sirup factory at Waycross, Ga., November 3 and completed December 7. In 25 days of grinding 12,240 gal. of sirup was produced from 560 tons of cane. The average quantity of sirup per ton of cane was 21.87 gal. The average percentage of total solids in the juice was 15.07 per cent; of sucrose, 11.16 per cent; of reducing sugar, 2.15 per cent, and the average purity coefficient 73.63 per cent.

Analyses of the finished sirups showed an average of 75.73 per cent of total solids, 46.05 per cent of sucrose, 24.49 per cent of reducing sugar, 21.69 per cent of inversion, and 93.41 per cent of total sugar in total solids.

The results secured in the 4 years' experiment in the fertilization of sugar cane, 1902-1905, are summarized at length in tabular form and discussed. Dividing the fertilizer and making 2 or 3 applications as compared with applying it all at one time did not show a sufficient advantage to justify the practice. The results obtained by applying half of an application of 2,000 lbs. of the normal formula at planting and the other half at a subsequent period of growth gave a very large increase in yield as compared with making the application all at one time. In some cases the data apparently indicated a loss in the efficiency of the fertilizer when applied at three successive intervals instead of at two.

In experimenting with the revised formula it was found inadvisable to use in connection with it an application of 200 lbs. of nitrate of soda per acre, either in one application with 1,200 lbs. of the revised formula or at intervals. The combinations of plant food represented by either the normal formula or the revised formula gave good results and no great advantage was shown in departing widely from these formulas. The quantities of plant food contained in the normal formula are considered necessary for the production of profitable crops of sugar cane on this type of soil, and the average results of the experiment are regarded as indicating that the crop of sugar cane may be about doubled by the application of these amounts of plant food per acre.

Annual report of the bureau of sugar experiment stations for the year 1905-6, W. MAXWELL (Ann. Rpt. Queensland Bur. Sugar Expt. Stas., 6 (1905-6), pp. 56).—Analyses of sugar canes grown by farmers and of water for irrigation purposes, together with results of variety tests of cane from different countries, and of culture, irrigation, and fertilizer experiments, are tabulated.

The following varieties ranking in the first class for commercial sugar production are retained in the experiment and carried to the third ratoon crop: New Guinea, 4, 8A, 15, 22, 24, 24A, 24B, 26, 38, 40, 64, and 66; Mave, Trinidad 60, Yuban, N. G. 37, 47, 48, 51, and 55. Mauritius Settlers and Bois Rouge were also continued either for distribution or for other purposes.

Irrigation supplying a maximum or some excess of moisture tended to lower the purity of the juice, and manures on irrigated and nonirrigated plats, while increasing the production of the cane, produced a similar result. It is stated

that these results are not without exceptions, and that upon thoroughly exhausted land the application of mixed manures very frequently results in an improvement of quality and yield. On irrigated plats the use of manures resulted in an additional yield of $4\frac{1}{2}$ tons of cane and of $\frac{1}{2}$ ton of sugar per acre, while without irrigation the manures gave an additional yield of $3\frac{1}{2}$ tons of cane, the increase in the sugar per acre being very small.

Cane from rows planted 4 ft. apart weighed 20 tons per acre more than cane from rows 7 ft. apart, and it was noted that the gradation was regular and progressive along the line of different widths. The cane from rows 4 ft. apart yielded $11\frac{1}{2}$ tons of sugar per acre, while that from rows 7 ft. apart yielded $2\frac{1}{2}$ tons per acre less.

Notes are also given on cane diseases, distribution of cane varieties, introduction of new varieties, subsidiary crops, substation work, and experiments in raising seedlings.

[**Cultivation of plant crop and ratoon stubble**], N. A. COBB (*Hawaiian Sugar Planters' Sta., Dir. Path. and Physiol. Bul. 5, 2, ed., pp. 85-96, figs. 4*).—Methods of opening up stools of plant cane and ratoon crops are described and illustrated, and the advantages from the treatment accruing to fields infested with root disease are pointed out. Hoeing the earth away from the base of the stubble of a poor plant crop, and thus letting the air and light into the old stool, resulted in a fair ratoon crop. The fact that the stool of ratoon stubble under certain soil conditions is very firmly embedded in the ground brought about the construction of implement embodying the principles of the disk plow and the subsoiler, for the purpose of breaking open the stool in order to expose it to the air and the sun and to induce better growth through root pruning. A description, with illustrations, of these implements is given.

Experiments in growing Cuban seed tobacco in Alabama, G. T. MCNESS and L. W. AYER (*U. S. Dept. Agr., Bur. Soils Bul. 37, pp. 32, pls. 3*).—Culture experiments with Cuban seed tobacco were conducted in 1903, 1904, and 1905. The soils taken for the experiments are described as Orangeburg clay and Orangeburg fine sandy loam, and their mechanical analysis is shown in tables. The climate of the region is also discussed, and the methods of soil preparation and cultivation are described in detail.

The object of the work was to demonstrate that a high quality of Cuban seed filler leaf can be produced on a certain soil and to secure information as to the value placed on the product by dealers and manufacturers.

In 1903 1 acre of tobacco was grown on Orangeburg fine sandy loam and 2 on Orangeburg clay. The yield amounted to 435 lbs. of merchantable tobacco to the acre. In 1904 $1\frac{1}{2}$ acres of each kind of soil were secured in a different locality for this work. The 3 acres yielded 1,380 lbs. of air-cured tobacco, but unfavorable conditions reduced the yield of commercial leaf to 1,001 lbs. This crop was produced at a cost of 23.7 cts. a pound.

In 1905 9 parties entered into a cooperative agreement and raised $12\frac{1}{2}$ acres of tobacco under the direction of the Bureau of Soils. The yield of merchantable tobacco from this acreage amounted to 4,457 lbs., or $356\frac{1}{2}$ lbs. per acre. The weight of the crop as harvested ranged from 260 lbs. to 848 lbs., and averaged 380 lbs. per acre. The largest yield was produced at a cost of 6 cts. per pound and the smallest at a cost of 12 cts. per pound. The reduction in cost of growing the heavier crop is regarded as due to better soil preparation. The profits from the largest yield amounted to \$114.05 on $1\frac{1}{2}$ acres, and from the smallest yield to \$10.02 on 1 acre.

The crop of 1903 sold for 30 to 40 cts. a pound, and the total amount realized was sufficient to cover the original cost of growing the tobacco, the expense of fermenting, sorting, and packing, the shrinkage in weight, and other losses.

In 1904 a free distribution of the crop was made to cigar manufacturers and dealers in leaf tobacco in order that their opinions as to the quality might be obtained. "From the letters received by the Department the tobacco seems to have given satisfaction."

Milling characteristics of Australian wheats, F. B. GUTHRIE and G. W. NORRIS (*Jour. Dept. Agr. So. Aust., 10 (1907), No. 7, pp. 392-405*).—In this paper it is pointed out that South Australian wheats are characterized by strength of flour, which is always of high color and good gluten content. The Victorian wheats, while producing flour of equally good color and gluten content, are lower in strength. The flour produced in New South Wales closely resembles that produced in Victoria and South Australia, but stands midway between these two varieties in respect to strength. The Queensland wheats show high bushel weights and a high percentage of flour, but in strength they are distinctly below the wheats of the 3 States just mentioned. Western Australian wheats give a flour of high color and fair strength, but deficient in gluten. The good points of New Zealand wheats are given as good yielding power, high bushel weight, and fair flour strength, and the weak points as lack of brightness in the grain, thick bran, chalky color of flour, and deficient gluten.

The improvement of English wheat, A. E. HUMPHRIES and R. H. BIFFEN (*Jour. Agr. Sci., 2 (1907), No. 1, pp. 1-16*).—This article is a résumé of the work of improving English wheat in various parts of England and is based on a paper presented on this subject to the international convention of millers at Paris in 1905. The quality of wheats from different parts of the world is discussed, and the results of various experiments conducted to determine the factors influencing the strength of wheat as shown by baking tests are noted.

It is pointed out that soil conditions have a considerable influence on the strength of wheat, though the experiments presented give no information as to the precise factor or groups of factors which determine this influence. In testing the influence of fertilizer applications on the strength of wheat wide differences in the results were observed, but the results show satisfactorily that long-continued manuring does not increase the strength of wheat and that it may even seriously depreciate it. In connection with one of these experiments it was found that the strength of the grain from highly manured plats increased abnormally with its age and that this marked improvement in quality on ageing coincided with a deficiency of phosphates in the ash of the grain. Spring sowing of wheat did not give results showing an increase of strength in the grain. Results also show that the time of harvesting may influence the strength, but not sufficiently to bring the best English varieties to rank with such wheats as those from Manitoba.

In addition to a review of these tests the work of comparing numerous foreign varieties is described. In this work it was found that the quality of some wheats changes considerably with climatic and soil conditions, while others retain their strength under all conditions. The Fife wheats were especially prominent in retaining their strength.

In order to obtain suitable varieties of wheat adapted both to the farmers' and millers' purposes the inheritance of strength was studied in great detail, and many hybrid varieties were originated and rigidly selected. It is stated that while strength and the lack of strength in wheat may not form a pair of Mendelian characteristics, the assumption that they do has proved very valuable in building up desirable varieties. So far about 40 types, mostly of Fife parentage, have been retained as proving satisfactory in all features, and these are now cultivated to determine their yielding power. These types are diverse in habit, some being loose, others square in the head, while some have

white and others red grain; but so far as may be determined the strength of the parent Fife has been maintained.

Twenty-ninth annual report of the Swiss seed control and experiment station at Zurich (*Landw. Jahrb. Schweiz*, 20 (1906), No. 2, pp. 553-576).—At the seed-control station 9,480 samples of 171 varieties, including clovers, grasses, cereals, root crops, various other forage plants, and tree and flower seeds were tested, and results with reference to purity and germination are tabulated and briefly noted.

In one experiment red clover obtained from Upper Baden gave a much smaller yield than a variety secured from Winkel, near Zurich. *Vicia pannonica* proved to be the hardiest and the most productive of 3 varieties of vetch, including *Vicia villosa*.

A comparison of flax from different sources showed that Riga flax grew taller and coarser than either Axam, Bohemian, or Oetzthal flax. Earlier results secured with Sicilian flax indicate that this variety is much coarser than any of these 4 varieties.

Distribution of seeds and plants, E. J. WICKSON and R. E. MANSELL (*California Sta. Seed Bul.*, 1906-7, pp. 7).—A brief statement of the seed distribution carried on by the station is given and notes on *Potentilla elata*, a dry land forage plant, common and durum wheats, leguminous plants for green manuring, and a number of field and garden crops suitable for California are presented.

Hints to homesteaders, L. R. WALDRON (*North Dakota Sta. Bul.* 74, pp. 263-280).—This bulletin contains advice to settlers on the new lands of North Dakota, particularly in the drier regions. The bulletin treats largely of grain, grasses, and woody plants, and contains notes on the rotation of crops, breaking prairie sod, and other lines of work incident to opening up new lands.

HORTICULTURE.

Market gardening, R. L. WATTS (*Penn. Dept. Agr. Bul.* 147, pp. 53, pls. 9).—This is designed to give plain, practical instructions in market gardening, and is based on the experiences of the author and other leading market gardeners.

Among the factors considered are the selection of site and soil, the equipment for raising early vegetables, the importance and use of different forms of fertilizers, liming of soils, tillage, and the source of seed supply. Plain cultural directions are given for all the well-known market garden crops, together with fertilizer formulas for different vegetables and tables showing the number of plants and quantity of seed required per acre for various distances.

Station novelties in truck crops and further distribution of seeds, B. D. HALSTED (*New Jersey Stat. Bul.* 199, pp. 30, pls. 4, figs. 7).—The plant breeding work and seed distribution previously noted (*E. S. R.*, 17, p. 864) was continued during the season of 1906, and the present bulletin consists largely of additional reports on novelties of former years and notes on others which have not yet been distributed.

The Malakhov-Premo cross of sweet corn has been called Malamo, and is said to produce much larger ears than and to be nearly as early as its parent Malakhov. The Malakhov-Crosby sweet corn, now called Malakosby, while not quite so early as the Malamo, has been received with favor, and is said to be remarkable for its vigor of stalk and large yield of superior ears. Notes are also given on further crosses of sweet corn, including Adams-Crosby and crosses of Golden Bantam with Essex Early, Country Gentleman, and Premier.

Of the novelties in tomatoes *Magnerosa* continues to give satisfaction. The

Marvel-Ponderosa, now called Marvelosa, is giving favorable results and will be further tested. Crosses of Crimson Cushion with Marvel and Matchless are also described. The Long White-New York Improved eggplant and the Delicious Bay-State squash crosses will be tested during the coming season.

Notes are given on 2 Chinese vegetables, Pe-Tsai and Pak-choi, the seed of which was received last spring from the Department of Agriculture. The latter is said to be quite like a cabbage in color and texture, while the former somewhat resembles a giant lettuce. These vegetables may be used either in the same manner as cabbage or cauliflower or in the making of salads.

The former list of seeds for distribution has been revised by eliminating such varieties as Voorhees Red sweet corn, Station Bush Lima bean, Station Yellow tomato, and the Jersey Belle eggplant, which have become well introduced throughout the State. A number of unpromising varieties have been discarded, and the present list contains many of the recent novelties.

Manuring fruit trees (*Belg. Hort. et Agr.*, 18 (1906), Nos. 23, pp. 360, 361; 24, pp. 376, 377; 19 (1907), Nos. 1, p. 9; 2, p. 25; 3, p. 44).—This article is devoted largely to a discussion of the various materials used for fertilizers, either alone or in combinations, in respect to their chemical nature and their use on soils of different composition and for different kinds of fruit trees. Brief notes on the benefits and methods of applying the fertilizers, together with suggestions for making fertilizer tests, are also given.

Grapevine culture, W. HARRIS (*Bul. Dept. Agr. [Jamaica]*, 5 (1907), No. 1, pp. 28, figs. 6).—During the past 18 years numerous articles and notes on different phases of grape culture have been published in the bulletins of the department of agriculture of Jamaica. This information has been collected and arranged under suitable headings and is here presented in pamphlet form for the convenience of grape growers.

The methods of propagation, selection of site, preparation of soil, planting, pruning, fertilizing, disbudding, thinning of the fruit, and diseases of the vine with their remedies are among the important phases considered, together with a discussion of varieties and the markets for grapes. An extensive bibliography pertaining to the culture of grapevines is also given.

The Cinsaut grape, J. W. MILLS (*Cal. Cult.*, 28 (1907), No. 9, p. 212).—The Cinsaut grape, which is described as a purplish black grape resembling the Black Malvoisie but possessing shorter and more compact bunches, is said to be especially adapted to the high and dry mesas of southern California which are incapable of being irrigated and are ordinarily too dry for the culture of most varieties of grapes. It is said to have met with much favor in the vicinity of the Pomona experiment station, but is not recommended for planting in humid lowlands where the fruit is liable to be tasteless and watery, with a high acid and low sugar content. When grown in warm, dry situations not subject to severe frosts after the budding season it is reported an excellent table grape, but must be gathered shortly after maturity since it soon loses its good qualities.

The author further states that this grape is grown extensively in the south of France, and yields a heavy-bodied but delicate and highly flavored wine, used widely in making blends. The average yield of fruit is given as 4 tons per acre.

The bagging of table grapes, O. OROIX (*Rev. Vit.*, 27 (1907), No. 687, pp. 173-176, figs. 3).—The author has conducted experiments in the bagging of table grapes, growing both on trellises and along walls, since 1901. The results obtained prior to the season of 1906 are said to be satisfactory in many ways, but considerable failure was noted on account of the scalding of the bagged fruits during continued periods of hot weather.

In 1906 a new style of bag was tried for the purpose of determining its value in eliminating this scalding. Previous to this time a thin, transparent paper bag

had been used, ventilation being afforded by cutting off the bottom ends of the folded bag and making a V-shaped cut in the center of the bottom. In the new bag the bottom was removed and a cloth covering added. The bag was reinforced with a cardboard band near the upper end, thus preventing it from coming in contact with the grapes, and it was also encircled near the lower edge with a fine brass-wire thread, by means of which it was possible to open the bottom during warm weather and nearly or completely close it during humid, rainy, or cold periods. After the bunch was inserted the bag was attached to the supporting vine in order not to hamper the normal development of the bunch stem. Over 600 bunches of grapes were treated in this manner, and the author states that the grapes enclosed in this way were much larger than those enclosed in the former poorly ventilated bag.

An experiment was also conducted to determine the effect of bagging the grapes before the flowering season. Several bunches were selected for this purpose at different heights on the trellis and vine. In this case the lower end of the bag was allowed to remain open. With the grapes thus treated there was no early dropping of the berries and they were larger and at least 10 days further advanced than unprotected grapes.

The 3 different periods which the author suggests as being suitable for bagging grapes are previous to the flowering season, in order to protect the bunches from the cold and wet spring weather; immediately after the grapes have been thinned, at which time the author secured his best results, and when the grapes begin to mature, in order to protect them from wasps and other insects as well as to retain the bloom of the grape. Sacking according to the method described is said to be very simple and inexpensive and has the advantage of affording opportunity for both thinning the berries and inspecting the condition of the grapes from time to time without the removal of the bags.

Aside from the increase in the size of the bagged grapes as compared with grapes grown in the open, the other advantages as the result of these experiments were that the bagged grapes were from 12 to 15 days earlier, and that, although they were slightly paler in color, the skin was very fine and transparent and had a slightly golden appearance, thereby causing them to resemble greenhouse-grown grapes. Bagging also served as a protection from insects and adverse weather conditions. It is stated that the grapes may be left on the vines in bags through December or even later where the winter temperature is not too severe, since they will easily withstand a minimum temperature of \pm to 5 degrees C. for a period of several days.

Fruit preserving, A. MENDOZA (*Jour. Dept. Agr. Victoria, 4* (1906), No. 11, pp. 674-679, figs. 3).—Brief instructions for amateurs are given for the preservation of fruits in various forms of glass and tin packages. The different methods of preserving are discussed and specific directions are given for the manufacture of sirup and the previous preparation of apricots, peaches, apples, pears, and quinces. The canning in tins is said to be more economical but not so convenient as canning in glass jars.

Directions are also given for the making of fruit pulp by simply boiling any kind of fruit which can be used for jam making or in similar ways with just sufficient water to cause the juice to run, so as to stew the fruit in its own moisture. When boiled sufficiently to sterilize it the pulp may be placed in bottles in a manner similar to that in ordinary methods of canning fruits. Nothing in the way of sugar or other matter is added to it.

Fruit preserving for domestic supplies, G. QUINN (*Jour. Dept. Agr. So. Aust., 10* (1906), No. 5, pp. 266-277, figs. 6).—Popular directions are given for the preparation and preserving of stone and pip fruits, berries, and vegetables,

and the making of preserving sirups, together with a discussion of the principle underlying fruit preservation and the appliances required for the work.

Opportunities in the South for preserving fruit and vegetables (*Tradesman*, 56 (1907), No. 12, pp. 47, 48).—A popular description is given of the various processes in the canning of tomatoes in the commercial canning houses of Maryland, and data are presented in connection with the canning industry, both of this State and California. A discussion of the possible development of the canning industry in those sections of the South where large quantities of truck crops and orchard fruits are grown is included.

[**Statistics with reference to the imports and acreages affecting British horticulture**] (*Jour. Roy. Hort. Soc. [London]*, 31 (1906), pp. 183-188).—Tabulated statistics are given showing the quantity and values of fruit and vegetables imported into England during the seasons of 1903, 1904, and 1905.

Of the total acreage in the United Kingdom only 245,815 acres, or less than 1 in 300, are under fruit cultivation. It is reported that the imports of fresh flowers continue to decrease from year to year, since forcing methods are becoming better understood in England. Some of the vegetables have been reported to be increasing in acreage, such as beans, potatoes, mangel-wurzels, cabbage, onions, and carrots, while a few of the chief root crops, such as turnips and swedes, show a slight decline.

FORESTRY.

First annual report of the State forester of Wisconsin, E. M. GRIFFITH (*Ann. Rpt. State Forester Wis.*, 1 (1906), pp. 67, pls. 12).—A report of the progress and condition of the State forest work for 1906, with recommendations for improving the State system of forest protection, management, afforestation, and taxation.

Considerable data is presented relative to forest conditions in various parts of the United States. Within the past 2 years the State forest reserves have grown from 40,000 to 234,072 acres. Arrangements have been made whereby the State board of forestry is to cooperate with the Forest Service of this Department on the various Indian reservations in Wisconsin. It is the policy of the State to withhold for forestry only those lands which are of no value for agricultural purposes.

The work of the fire wardens is given in tabular form. The number of forest fires reported for 1904 was 140, and the number of acres burned over, 56,777. In 1905 there were 160 fires, in which 76,125 acres were burned over. Over half of these fires are said to have been started by settlers clearing land and burning for pasture.

An appendix contains the State forestry laws of 1905, under which the forestry board was established. The report is illustrated by several photographs, reproduced by permission of the Forest Service, pertaining to forest problems in different parts of the United States.

Annual report upon state forest administration in South Australia 1905-6, W. GILL (*Ann. Rpt. State Forest Admin. So. Austl.*, 1905-6, pp. 12, pls. 6).—This is a report of the year's progress in forest investigations and in the operation of forest reserves and plantations in South Australia, and is similar in nature to previous reports (E. S. R., 16, p. 880).

The total area of forest reserves for the fiscal year 1906 was 170,135 acres. During the year 101 acres were inclosed for planting and reforestation, making a total of 14,122.25 acres inclosed. Of 81,544 trees planted during the year 53,407, or 65½ per cent, are reported as living. During the past 24 years the

department has distributed 6,484,675 trees in response to applications from 30,223 persons. The date palms which have been under observation for several years made satisfactory growth during the season and bore a full crop which, however, was later damaged by heavy rains at the ripening period.

An appendix contains tabulated statements of trees planted and alive, amounts of expenditures and receipts, and a comparative statement of revenue, expenditure, and legislative provision for the past 30 years ending June 30, 1906, together with several illustrations giving an idea of the extent of the plantations and development of the timber.

Review of forest administration in British India for the year 1904-5, S. EARDLEY-WILMOT (*Rev. Forest Admin. Brit. India, 1904-5*, pp. 11 + 60, map 1).—This review deals with the various forest operations for 1904-5 and is of a similar nature to that of the previous year (E. S. R., 17, p. 1160).

There have been several alterations in area in the different provinces, but the total forest area of 232,941 sq. miles shows little increase over the preceding season. The working plans in force at the end of 1905 included an area of 37,977 sq. miles. The total yield of timber and fuel was 251,568,276 cu. ft., 215,261,179 bamboos were cut, and minor forest products to the value of 5,816,926 rupees were produced. The net increase of timber and fuel over the preceding year amounted to over 19,000,000 cu. ft., and about 17,000,000 more bamboos were extracted than in 1903-4. The gross revenue for the year was 24,029,950 rupees and the gross expenditure 12,967,856 rupees. Of the exotic species of seeds tested in the United Provinces the American hardy catalpa was the most successful, 2,000 out of 2,500 seeds sown having germinated.

Several appendixes are devoted to tabulated data dealing with forest areas and surveys, expenditures, products, receipts, etc. A map is given which shows the progress of forest surveys in India.

Sand-binding and afforestation in southwestern France, JENTSCH (*Forstw. Centralbl.*, 29 (1907), Nos. 1, pp. 10-31; 2, pp. 77-96, pl. 1, figs. 9).—An extensive account is given of the reclamation and afforestation of about 800,000 hectares of formerly barren sands along the coast of southwestern France. Among the important phases considered are the planting systems, species of trees used, silvicultural practices, the systems of exploitation, and the products and revenues of the forests.

The walnut in Oregon, C. I. LEWIS (*Oregon Sta. Bul.* 92, pp. 43, pls. 23).—This bulletin is designed to meet the "present urgent need" for information concerning nut culture in Oregon, and is based largely on the experience of the Pacific coast nut growers.

The subject-matter deals with the important phases of propagation, planting, subsequent care, harvesting, marketing, and diseases and insects, as well as suitable soils and varieties. The introductory remarks give the present status of nut culture in Oregon, together with the principal nut-growing sections. The Oregon nut growers are of the opinion that the late-blooming French varieties are best adapted to that region, and of these Mayette and Franquette are the general favorites.

Florida soap trees, "Saponidas manatensis utilis" and "S. saponaria," E. MOULIE (*Amer. Soap Jour. and Manfr. Chem.*, 17 (1907), No. 6, pp. 124, 125).—The berries of the soap bush (*Sapindus utilis*) in Algeria are said to be rich in an alkaline principle known as saponin, useful in the manufacture of soap.

Two or more species of *Sapindus* grow in Florida, and the author states that he has been successful in producing saponin from 2 species of Florida soap trees, which he designates as *Saponidas manatensis utilis* and *S. saponaria*. The characteristics and possible uses of this oil are discussed. The author is

of the opinion that a large number of seeds from both the Florida and Algerian forms will be planted in Florida with the view of developing the industry.

Rubber in the East, J. C. WILLIS, M. K. BAMBER, and E. B. DENHAM (*Peradeniya Manuals, 1906, No. 1, pp. VIII+269, pls. 24, figs. 7, maps 7*).—This is volume 1 of a series of manuals on tropical botany, entomology, agriculture, and horticulture, which are to be written by the staff of the Peradeniya institution and other writers and published at intervals. It contains the official account of the Ceylon rubber exhibition held in the Royal Botanic Gardens, Peradeniya, September, 1906.

In the several lectures delivered at the exhibition the various phases of rubber, from cultivation to vulcanization, were considered, together with a discussion of cotton, tobacco, camphor, lemon grass, and citronella. These lectures, together with the discussions following them, have been revised and arranged in logical order with the purpose of making this account a standard treatise upon the rubber industry as it exists at present. The cultivation of rubber in Ceylon and other countries is described, the treatment of diseases, catch crops for rubber plantations, tapping knives, machinery for the treatment of latex or rubber, shipping, marketing, vulcanization, etc.

Para rubber: Distance and interplanting, H. WRIGHT (*Trop. Agr. and Mag. Ceylon Agr. Soc., 28 (1907), No. 1, pp. 2-9*).—The author discusses somewhat at length the following 5 systems of planting Para rubber trees: Close planting—permanent; close planting and thinning out; wide planting—permanent; wide planting with catch and inter-crops, and interplanting with herbaceous and arborescent plants.

The permanent—close and wide planting systems—are not considered of much value, since the former is said to be wrong in principle and the latter extremely wasteful. The author is in favor of those systems which allow the provision of increased root area as the rubber trees advance in age and increase in size. This may be brought about by thinning out the rubber trees, inter-crops, and other plants from time to time.

Cultivation of Manizoba rubber (*Manihot glasiiovii*), R. U. URIBE (*Bol. Soc. Agr. Mericana, 31 (1907) Nos. 7, pp. 121-124; 8, pp. 143, 144*).—An account of the cultivation of the "Manizoba" rubber tree in Brazil, including a botanical description and notes on adaptability to climate and soil, planting, cultivation, methods of exploitation, and yields.

The author considers the "Manizoba," which is generally known as *Manihot glasiiovii*, or the Ceara rubber tree, especially adapted to the conditions in Colombia, where it is believed that the financial returns would be greater than from cotton, sugar cane, or coffee, especially if the trees were planted by small farmers who could manage and gather the rubber themselves.

The bamboo and its uses, ERGATES (*Natal Agr. Jour. and Min. Rec., 9 (1906), No. 12, pp. 1175-1177, pl. 1*).—The bamboo is said to be of great value as a wind-break for fruit crops and as material for making fruit boxes and ladders, as well as in the construction of walls and doors for sheds and stables, water troughs for poultry, and handles for hammers and other small implements.

The method of making bamboo fruit boxes is described. The ends of the smaller boxes are made of solid wood, while those of the larger boxes are made of square frames filled in with small bamboo slats, with the sides of bamboo slats. A box 2 ft. 2 in. by 1 ft. 6 in. and 9 in. deep is said to cost about 30 cents. At present the limited supply of bamboo does not warrant the manufacture of these boxes as an independent business.

DISEASES OF PLANTS.

Report of the phytopathological section of the agricultural institute, 1906, E. MARCIAL (*Bul. Agr. [Brussels], 23 (1907), No. 1, pp. 39-47*).—After a tabular list of diseases that have been reported upon during the year, notes are given on a number of those which were most troublesome, with suggestions for their control. Among those described are bean anthracnose, downy mildew of grapes, cherry scab, and apple scab.

Some publications in 1906 on the heterœcism and specialization of Uredineæ, E. FISCHER (*Bot. Ztg., 2. Abt., 65 (1907), No. 4, pp. 49-54*).—The author briefly reviews the published results of Arthur, Fischer, Müller, Schneider, Shear, Tranzschel, and others relating to the heterœcism of various species of Uredineæ and the specialization of forms on certain host plants. Most of these publications have been noted elsewhere.

Volunteer wheat and rust, E. J. BUTLER (*Agr. Jour. India, 2 (1907), No. 1, pp. 99, 100*).—It is said that in some countries the outbreak of rust in wheat is ascribed to the carrying over of the fungus on volunteer wheat. This theory of propagating the fungus can hardly be accepted in India, as it is said that the weather is so hot after a crop is cut that usually no plants can be found until the next crop is sown. In addition, it has been learned that the rust spores themselves can not survive exposure to the intense heat that is experienced in the hot weather months. In order to explain the annual appearance of rust in India through the medium of volunteer wheat, the author says that it will be necessary to assume a combination of conditions that does not exist.

Smut diseases of cereals and a method for combating them, O. APPEL and G. GASSNER (*Mitt. K. Biol. Anst. Land u. Forst., 1907, No. 3, pp. 20, figs. 8*).—A summary is given of the present state of information regarding cereal rusts, the species described being *Ustilago tritici*, *U. hordei*, *U. jensenii*, *U. avenæ*, *U. levis*, *Tilletia tritici*, and *T. levis*.

Since the infection takes place through the flowers and treatment of the seed is of doubtful expediency, the author recommends for the prevention of loose smut of wheat and barley the selection of seed from isolated noninfested regions. For the bunt or stinking smut of wheat, black or hard smut of barley, and both the loose and covered smuts of oats seed treatment is said to be efficient.

A description is given of a form of apparatus that has been devised for the hot-water treatment of seed, in which the proper temperature is maintained by steam.

A grass-killing slime mold, J. W. HARSBERGER (*Proc. Amer. Phil. Soc., 45 (1906), No. 184, pp. 271-273*).—In August, 1905, the author's attention was called to a lawn in which the grass was being destroyed in areas varying from a few inches to several feet in diameter. The trouble seemed to begin after a series of night showers, the grass having become blackened here and there over the lawn. Subsequently it was reported that only the blades of the lawn grasses were destroyed, and that after the disease had disappeared the grass regained its fresh bright green color.

Specimens of the dead grass were submitted for examination, and the author reports having found them infested with the slime mold (*Physoarum cinereum*). The abundant production of the plasmodium of this mold had caused the destruction of the grass, and its occurrence on the living grass leaves demonstrates that the organism had changed its habit from that of a saprophytic life to a parasitic one.

Concerning a fungus-free darnel, E. HANNIG (*Bot. Ztg., 1. Abt., 65 (1907), No. 2, pp. 25-28*).—A report is given on studies of *Lolium temulentum*, particu-

lar attention being given to the occurrence of a race of this species which does not appear to be infested by the fungus to which the poisonous properties of darnel are attributed.

Selection for disease-resistant clover, S. M. BAIN and S. H. ESSARY (*Tennessee Sta. Bul., Vol. XLX, No. 1, pp. 10, figs. 5*).—In carrying on their investigations with clover anthracnose (*Colletotrichum trifolii*), a preliminary report of which has already been given (*E. S. R., 17, p. 567*), the authors found that in some badly infected fields there were here and there individual plants that possessed a high degree of resistance. With this fact in mind, a series of experiments was planned to develop a resistant strain of clover, and a preliminary report is given of the results thus far obtained.

In one of the experiments a plat was planted with seed from resistant plants obtained from different sources, and comparisons made with ordinary commercial seed grown under similar conditions. After seeding the plats they were covered with infected hay in order to insure the presence of the disease among the selected plants. Toward the close of the season 95 per cent of the seedlings from the resistant plants were alive, while not more than 5 per cent from the nonselected plants had survived the disease.

The investigations thus far carried on indicate that there is a strong resistance on the part of some plants toward this disease. This fact has been taken advantage of as rapidly as possible, but as yet no seed is available for distribution.

Spraying potatoes, E. J. BUTLER (*Agr. Jour. India, 2 (1907), No. 1, pp. 95, 96*).—An account is given of potato spraying experiments in which 3 plats were sprayed in duplicate with Bordeaux mixture. One plat was sprayed with plain Bordeaux mixture, the second with Bordeaux mixture to which a small quantity of resin-soda solution was added, and the third with Bordeaux mixture containing unrefined sugar. The quantity of Bordeaux mixture used was at the rate of about 300 gal. per acre, 60 gal. being applied at the first application and 120 gal. at each of the other applications.

The yield of the different plats is shown, from which it appears that the spraying resulted in a substantial profit. The largest returns were obtained from the plats sprayed with Bordeaux mixture to which resin and soda were added, followed by Bordeaux mixture containing sugar, and plain Bordeaux.

Some elements of plant pathology, N. A. COBB (*Hawaiian Sugar Planters' Sta., Div. Path. and Physiol. Bul. 4, pp. 50, figs. 32*).—This is an address on the diseases of plants especially related to sugar cane delivered by the author before the annual meeting of the Hawaiian Sugar Planters' Association.

Fungus maladies of the sugar cane, N. A. COBB (*Hawaiian Sugar Planters' Sta., Div. Path. and Physiol. Bul. 5, pp. 25, pls. 8, figs. 102*).—A report is given on investigations of a number of diseases of sugar cane, together with notes on associated insects and nematodes. Among the diseases described are root diseases, leaf-splitting blight, rind disease, pineapple disease, and a disease to which the name "cleau" is given.

The principal root disease described is that due to the basidiomycetous fungus *Uthyphallus coralloides* n. sp. This disease is estimated to cause in some districts losses amounting to 10 per cent of the ratoon crop, with somewhat less on fields of plant cane. The fungus, which is almost entirely a subterranean one, only coming to the surface of the ground when the fructifications are formed, attacks the cane through wounds and the cut ends of the plant cane, from which it spreads along the fibrovascular bundles into the interior of the plant. It was found that flies play an important part in spreading the spores of the fungus, and extended studies were made on the rôle of flies and other insects in the dissemination of this disease. In addition to the

Thyphallus considerable injury is caused by *Marasmius sacchari hawaiiensis* n. var., which also attacks cane, causing a root disease. The best means for combating the root diseases are cultural methods, the use of resistant varieties, the destruction of the fructifications, and the eradication of flies.

The leaf-splitting blight, caused by *Mycosphaella striatiformans* n. sp., is especially destructive to young cane, particularly during the cool season. The leaves show alternate colorations, and the tissues dry up, after which the leaves split badly. No remedies are known for holding this disease in check.

The rind disease described is due to *Trichosporia sacchari*, and it is said to be a well-known disease that follows wounds on cane. It is very prevalent on some plantations, and is to be combated by the use of resistant varieties and the complete destruction of the spore-bearing dead stalks.

The pineapple disease (*Thielaviopsis ethacetica*) attacks plant cane through the cuttings. It is characterized by a peculiar discoloration running through the cane, accompanied by a more or less pronounced pineapple odor. The soft varieties of cane seem very susceptible to this disease, and the use of tops for planting is advised. In making cuttings for planting care should be taken not to shatter the ends of the cane, and it has been found desirable to treat the cuttings before planting with some fungicide such as Bordeaux mixture. This fungus also attacks pineapples, sometimes causing severe losses.

The disease called clean is widespread, but does not seem to be of very great economic importance. Young stalks are attacked here and there in the field and appear discolored and shrunken, with dry leaves and leaf sheaths bound together. Insects appear quite commonly within the leaf sheath and they are possibly concerned with the disease.

Technical descriptions are given of the different fungi concerned in these diseases and about a score of new species of nematodes are described. These are included, as the wounds formed by nematodes on the roots aid fungi in gaining entrance to the cane plant.

The heart rot of beets, C. MERLE (*Sucr. Indig. et Colon.*, 69 (1907), Nos. 5, pp. 125-129; 6, pp. 148-152).—A description is given of beet root rot, due to *Phoma beta*, or *P. tabifica* of some authors, the ascigerous form of which is now recognized to be *Sphaerella tabifica*.

The disease usually makes its appearance late in summer, and seems most destructive on certain types of soil during prolonged drought and on certain varieties. Sandy soils containing an abundance of silica with rather impervious subsoil appear to favor its spread. Associated with the fungus causing the root rot are a number of other species, but they are shown to be completely saprophytic.

For the prevention of loss by this disease the author recommends deep plowing before the beginning of winter, the application of large quantities of wood ashes to the soil, long rotation, and the planting of some of those varieties that have been shown to be resistant to the fungus attacks.

Cabbage leaf spot (*Gard. Chron.*, 3, ser., 41 (1907), No. 1054, p. 164).—In response to an inquiry the editor states that the conidial stage of *Sphaerella brassicicola* has become unusually common and destructive in parts of England. For its prevention it is recommended that diseased plants be pulled up and burned, the soil disinfected, and no cruciferous plants allowed to occupy the soil for at least 2 years. Any unaffected plants should be sprayed with Bordeaux mixture so as to prevent infection. The fungus seems to be becoming increasingly destructive, and it is urged that means be taken to prevent its spread by burning the dead leaves and other refuse.

Stem canker and drop of cabbage plants, J. RITZEMA BOS (*Ztschr. Pflanzenkrank.*, 16 (1906), No. 5, pp. 257-276, figs. 13).—As a result of studies

carried on for a considerable period, the author has determined that the stem canker and the drop of cabbages are manifestations of the same disease, both being caused by the fungus *Phoma oleracea*. A technical description is given of the fungus, and the effect which it produces upon the host plant is described.

The practice of leaving cabbage stalks standing in the field is condemned, as the fungus is carried over the winter in them. Investigations seem to indicate that the fungus can not attack sound roots, but must find entrance through wounds and insect injuries. In the latter class especial attention is called to the cabbage maggot (*Anthomyia brassicae*), which should be rigorously attacked in order to prevent injuries which may be followed by the fungus.

A spot disease of stone fruits, P. VOGLINO (*Italia Agr.*, 1907, pp. 12, 13, pl. 1; *abs. in Riv. Patol. Veg.*, 2 (1907), No. 7, pp. 104, 105).—A disease of cherries, peaches, and almonds, in which the leaves, twigs, and maturing fruits are attacked by the fungus *Clasterosporium carpophilum*, is described. The fungus produces discolored spots on the foliage and soon the tissues in these areas dry and fall out, the leaves presenting a ragged appearance. Sometimes a copious exudation of gum accompanies the disease, but the author was unable to establish any relation between the fungus and the formation of gum. It is believed that the gum is due to the arrested development of the cambium.

Spraying trees at frequent intervals with a 5 per cent solution of copper and iron sulphate and lime has given good results. The application of a solution of 10 per cent iron sulphate and 5 per cent lime to the trees during winter is recommended as an additional precaution.

Pear canker and means for its control, G. PAPAIOZZI (*Rome: Offic. Poligrafica Ital.*, 1906, pp. 29, figs. 7; *abs. in Riv. Patol. Veg.*, 2 (1907), No. 7, pp. 103, 104).—An experimental study was carried on to determine the etiology of pear canker, the relative resistance or predisposition of different varieties to the disease, and the efficiency of various methods of control.

The cause of the canker was found to be the fungus *Nectria ditissima* following frost injuries. If protected from the action of cold no canker was found on pear trees. Wide variations were found in predisposition to the disease, and in making plantings in exposed regions susceptible varieties should be omitted. When cankered areas are observed on trees they should be cut out, and the wound treated with carbolic acid or corrosive sublimate, after which it may be covered with a mixture of resin, alcohol, and coal dust.

Experience in combating grape downy mildew in 1906, HENSLEY (*Prakt. Bl. Pflanzenbau u. Schutz*, n. ser., 5 (1907), No. 2, pp. 18-23).—An account of a series of experiments with Bordeaux mixture for the prevention of downy mildew of grapes due to *Peronospora viticola*.

Various strengths of the fungicide were used, and although the season was a very rainy one, the results obtained were so encouraging that the author feels warranted in recommending the treatments for 1907. He suggests that the vines be thoroughly sprayed with not less than a 2 per cent solution of Bordeaux mixture. The first application should be given in May when the young shoots have attained a length of 20 to 25 cm. The second spraying should be made just before the opening of the flowers, followed by a third immediately after the flowering period is over. Two or more additional applications should be given at intervals during the season, depending on the state of the weather and the development of the fruit. There is said to be no economy in the use of very dilute solutions, and thoroughness of application to all parts of the vine is a prime requisite for the success of the treatment.

Localized stem blight in Ohio vineyards, A. D. SELBY and J. M. VAN HOOK (*Ohio Sta. Circ.* 64, pp. 6, figs. 2).—In August, 1906, the authors' attention was called to an extensive dying of grapevines in Ashtabula County, Ohio. The

trouble had become serious in 1905, and at the time of the authors' visit in 1906 it was found that many of the vines had died. In some cases the old roots had put out sprouts, some of which were wilting, and in some instances new vines had been planted in place of the old ones.

The wilting of the vines is a conspicuous character of the disease, the leaves and tender shoots first showing by their wilting that the disease is present, after which they droop and finally dry up, while the berries are shriveled. In studying the winter condition of the disease the authors found that if the old bark is stripped off the diseased stems, on the inner bark will be found rows of black dots arranged more or less in longitudinal elevations.

A study of specimens showed that they were identical with the parasite reported by Atkinson in New York in 1904 and referred by him to a form of the grape anthracnose.

While investigating this disease the authors found that it was also present in a 13-year-old vineyard at the station. This vineyard had been regularly and thoroughly sprayed with Bordeaux mixture, followed by ammoniacal copper carbonate, but the presence of the disease seems to reflect against the efficacy of Bordeaux mixture alone as a remedy against this disease.

Based upon investigations carried on in Europe and elsewhere, the authors recommend the spring treatment of all vines with a solution of iron sulphate, sulphuric acid, and water. As a precautionary measure it is recommended that diseased portions of vines be cut out and burned.

In order to study more thoroughly the distribution of the fungus, the authors request correspondence relating to it and ask that suspected specimens be sent them.

A mulberry disease in Kashmir, E. J. BUTLER (*Agr. Jour. India*, 2 (1907), No. 1, pp. 97, 98).—An account is given of a serious disease of mulberries which has not previously been recorded in India. The disease is found in old trees without causing appreciable damage, but great harm is done to young plants in nurseries, a fungus attacking the seedlings in their second or subsequent years. It is said not to kill the seedlings outright, but as the affected plants have to be cut back below the diseased parts, several years' growth is lost.

The disease is said to be caused by the fungus *Coryneum mori*, which invades the wood and young branches and results in the withering of the branches, which drop their leaves.

This disease is already known in Japan, and it is possible that it was introduced into India from that country. How serious it is likely to prove it is as yet impossible to predict, as methods for its control are not known.

The coffee nematode, G. GÁNDARA (*Com. Par. Agr. [Mexico] Circ.* 51, pp. 7, figs. 6).—A description is given of attacks of *Heterodera radicecola* on coffee, and attention is called to the loss which this nematode has caused to coffee plantations in Brazil and elsewhere. The effect on the host plant is noted, after which various cultural remedies are described. In addition to methods of cultivation that are based upon stimulating the growth of the trees, it is suggested that various substances be injected about the trees for the destruction of the nematodes. Among those mentioned are gasoline, benzine, iron sulphate, carbon bisulphid, sulphocarbonate of potassium, etc.

A good method for combating *Pestalozzia palmarum* on coconut palms, C. BERNARD (*Teysmannia*, 17 (1906), No. 10, pp. 654-657).—For preventing the spread of *P. palmarum* on coconut trees the author recommends a treatment which has been found efficient on an estate in Java. This consists in cutting out the diseased portions of the tree as soon as the fungus spots appear and burning or deeply burying the material. The author adds the precaution of

burning all fallen rubbish about the trees and treating the prunings with a solution of corrosive sublimate before burying them.

The tulip disease and its prevention or cure (*Gard. Chron.*, 3. ser., 41 (1907), No. 1055, p. 168).—The writer states that many complaints from Holland, Germany, and elsewhere have been received relating to the failure of tulips to bloom, and a report is given on experiments for the control of this disease. These experiments are based upon the observations of Klebahn that the disease is due to 2 fungi, *Botrytis parasitica* and *Sclerotium tuliparum*.

The *Botrytis* form usually shows itself in the early spring by the backward, sickly appearance of the first tulip sprouts or by their failure to appear altogether. Upon lifting the diseased bulbs small black fungus spots will be observed upon them, or if affected by the *Sclerotium* the spots will be larger and dark brown in color.

As these fungi remain in the soil for a number of years, the treatment undertaken is based upon the removal of the fungus, and the only practical plan thus far advised is to lift out the bulbs that show signs of disease, together with the surrounding soil, as early in the spring as possible and to destroy the bulbs and completely sterilize the soil by burning it. This treatment, persisted in for a number of years, it is claimed has resulted in the eradication of the disease from a large tulip nursery in Holland.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

The fox: A dangerous pest, and a plea for its extermination, S. McINTOSH (*Jour. Dept. Agr. So. Aust.*, 10 (1907), No. 6, pp. 373, 374).—Attention is called to the rapid multiplication of the fox in South Australia. This animal is an introduced species and may be considered of some benefit in destroying rabbits. The author fears, however, that it will ultimately multiply to such an extent as seriously to threaten the poultry and sheep business.

Insects as the food of squirrels, W. T. DAVIS (*Canad. Ent.*, 39 (1907), No. 1, p. 16).—Squirrels were observed opening hickory nuts for the purpose of obtaining the larvæ of snout beetles in them. Notes are also given on other insects occasionally eaten by squirrels.

A study of the stomach contents of native carnivorous birds, G. RÖRIG (*Arb. K. Biol. Anst. Land u. Forstw.*, 5 (1906), No. 5, pp. 237-265).—The author made an examination of the stomach contents of 1,154 carnivorous birds, including eagles, fishhawks, and various other hawks and owls. The results of these investigations are presented in a tabular form showing the percentages of beneficial and injurious animals which constitute the food of the birds.

The digestion of various food stuffs in the stomach of crows, G. RÖRIG (*Arb. K. Biol. Anst. Land u. Forstw.*, 5 (1906), No. 5, pp. 266-278).—In studying the stomach contents of birds for the purpose of determining their food habits, it is desirable to know the rapidity of digestion of the various elements of food in the species which is being studied. The author found that when the stomach is filled with a considerable variety of food the softer parts of animal origin rapidly disappear, while hard elements remain in a recognizable form not much longer than the hulls of grain. All of these hard elements seem to retain their original form longer when the quantity in the stomach is smaller and the variety of food elements less.

The bone content of the pellets of *Asio otus*, M. SCHWARTZ (*Arb. K. Biol. Anst. Land u. Forstw.*, 5 (1906), No. 5, pp. 279-281, pl. 1, fig. 1).—In studying the pellets cast up by this species of owl, the author finds that in most instances the bones are left in their original relation to one another, the softer parts having disappeared under the influence of the digestive juices.

International catalogue of scientific literature. N—Zoology (*Internat. Cat. Sci. Lit.*, 4 (1906), *pts. 1, pp. VIII + 405; 3, pp. XII + 384*).—The zoological literature indexed in these two parts of the international catalogue is mainly that of 1904, but also includes a number of entries of literature published from 1901 to 1903. As in previous parts of this catalogue, the material is indexed under the author's name and also by subjects.

Second biennial report of the commissioner of horticulture of the State of California, 1905-6 (*Bienn. Rpt. Comr. Hort. Cal.*, 2 (1905-6), *pp. 557, pls. 4, figs. 169*).—The reports of the commissioner of horticulture for the two years under consideration are given by E. Cooper (pp. 7-19), and a report of the deputy commissioner is presented by E. M. Ehrhorn (pp. 20-27).

A large part of the report is occupied with entomological matter, including an outline of entomology by J. Isaac (pp. 35-154); The Coccidae of California, by E. K. Carnes (pp. 155-222); Insects of the Year, by E. M. Ehrhorn (pp. 223-230); The Codling Moth Parasite (pp. 231-235); The Gipsy and Brown-Tail Moths (pp. 236-238); and An Experiment in Silk Raising, by K. Kurosawa (pp. 261-270). After 2 years' experience with *Caliphialtes messer* as a parasite of the codling moth, a number of fruit growers speak of the work of this parasite in favorable terms, but its practical value is not yet established beyond question. Brief reports are made by the various county boards of horticultural commissioners regarding insect pests, fungus diseases, and the status of fruit growing (pp. 273-314).

The proceedings of the thirty-second State fruit growers' convention, held at Hanford, December 4-7, 1906, are included in the report (pp. 315-549). At these meetings popular addresses were given and articles read on various matters connected with the growing of fruit.

Sixth report of the State entomologist, W. E. BRITTON (*Connecticut State Sta. Rpt. 1906, pt. 4, pp. XII+219-306, pls. 15, figs. 13, map 1*).—The chief lines of work undertaken by the entomologist during the year are briefly discussed.

Considerable attention was given to nursery inspection, and a statement is made regarding the condition of nurseries, together with an account of the treatment of nursery stock by fumigation and other methods.

A determined effort is being put forth to gain control of the gipsy moth in Connecticut, which has slowly spread from Stonington, where it was first discovered. The methods adopted in the control of the gipsy moth are similar to those applied in Massachusetts. The Bureau of Entomology of this Department is cooperating with the State authorities in this work.

The entomologist has also made a study of the spiny-elm caterpillar and the insects which have been found injurious to the tobacco crop in the State. These include cutworms, wireworms, hornworms, flea beetles, grasshoppers, plant lice, cigarette beetles, etc. Notes are presented on fumigation houses and on the use of hydrocyanic-acid gas and carbon bisulphid for the destruction of insects. In spraying for the San José scale no injury was observed to buds or twigs from the use of lime-sulphur mixtures. Fairly good results were also obtained from the application of proprietary miscible oils, but the lime-sulphur mixture is recommended as being the cheapest and most effective.

First biennial report of the Wyoming State board of horticulture, 1905-6, A. NELSON (*Bienn. Rpt. Wyo. Bd. Hort.*, 1 (1905-6), *pp. 56, figs. 31*).—A statement is given of the organization of the horticultural board of Wyoming, with copies of the State horticultural law and the regulations of the board. Particular attention is devoted in this report to the requirements of the nursery law, its enforcement, and benefits. Considerable time has been spent by the secretary of the board in field work, explaining the purpose of the law, and awakening interest in the control of insect and fungous diseases.

Suggestions are given regarding the location of orchards and varieties to obtain the best results and on insects and fungus diseases which are recognized by the law. Formulas are also included for the preparation and application of insecticides and fungicides.

Insects new or unusual in Michigan, R. H. PETTIT (*Michigan Sta. Bul.* 244, pp. 87-111, figs. 23).—During the past few years a number of new insect pests have appeared in Michigan and well-known insects previously unimportant in the State have caused considerable damage. Biological and economic notes are given on these pests, including strawberry louse, cutworms, Mediterranean flour moth, greenhouse leaf tyer, wheat midge, strawberry-root worm, powder-post beetles, strawberry weevil, wheat jointworm, etc.

Report on the work of the section for plant protection, C. BRICK (*Hamburg. Bot. Staatsinsit. Jahresber.*, 1905, pp. 24-39).—During the year under report nearly 246,000 packages of fruit were imported through Hamburg, and of this number 239,000 came from America. Among apples, the Baldwin constituted 43 per cent of the total import. An examination for San José scale showed that 10 per cent of the fruit was infested. Notes are given on a number of other scale insects found on fruit and plants and on the injury caused by woolly aphid, cutworms, bark beetles, and other pests in the vicinity of Hamburg.

Entomology, H. S. LAWRENCE (*Ann. Rpl. Dept. Agr. Bombay.* 1905-6, pp. 6-8).—The locust plague has abated to a great extent, and it is not believed that serious deprecations will be committed by these insects for some years to come. Particular attention is given to *Acridium succinctum* as well as to white ants, *Earias insulana*, etc. Mention is also made of the possibility of the accidental importation of cotton boll weevil.

Some injurious orchard insects, G. H. CARPENTER (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 7 (1907), No. 2, pp. 243-249, figs. 5).—Brief notes are given regarding the preparation and application of suitable insecticides for the control of codling moth, currant sawfly, plant lice, red spiders, scale insects, etc.

Catalogue of the Ephydridæ, with bibliography and description of new species, B. J. JONES (*Univ. Cal. Pubs., Ent.*, 1 (1906), No. 2, pp. 153-198, pl. 1, figs. 4).—A list is given of the Ephydridæ collected in California, together with a bibliography of the subject, a description of a number of new species, and a catalogue of all known species, with a key for identification.

An investigation of evolution in chrysomelid beetles of the genus Leptinotarsa, W. L. TOWER (*Washington: Carnegie Inst., Washington.* 1906, pp. X+321, pls. 30, figs. 31).—For a period of about 11 years the author has studied the methods of evolutionary transformation in animals as illustrated by the members of the genus *Leptinotarsa*. A large part of the investigations were made on the Colorado potato beetle with particular reference to its geographical races.

A number of experiments were tried, during which it was found that deviations in temperature under which specimens of the Colorado potato beetle were kept acted simply in accelerating or retarding the pigmentation, and that the variations thus produced had no significance in subsequent generations. Data collected on the gradual distribution of the Colorado potato beetle in this country are of much value to students of this insect.

With regard to the bearing of his studies on evolution, the author concludes that the members of the genus *Leptinotarsa*, including the Colorado potato beetle, have undergone direct rapid transformations in response to environmental stimuli as a result of geographical dispersion.

The cabbage and onion maggots, J. B. SMITH and E. L. DICKERSON (*New Jersey Stat. Bul.* 200, pp. 27, pls. 9, figs. 4).—A series of experiments was car-

ried out with various cultural and remedial measures for the control of these two root maggots. Cultural methods include the destruction of rubbish about fields where the crops are grown and the disinfection of sheds or crates in which the crops are stored. It has been found better to plant the onion sets in late September or October rather than in August or early September. A good fertilizer should also be applied, and the ground should be kept thoroughly stirred about the growing plants, whether cabbage or onions.

Among the specific treatments applied to the control of these pests a mixture of carbolic acid and lime containing 1 tablespoonful of carbolic acid and enough lime to make a paste in a gallon of water gave the best results. Considerable benefit was also noted from the use of tarred paper cards about the plants and kerosene, powdered tobacco, white hellebore, and dry lime.

Where an infestation has already taken place, direct destructive measures may be used, such as carbon bisulphid, carbolic-acid emulsion, and a decoction of hellebore.

Two new pests of carrots, C. BÖRNER (*Arb. K. Biol. Anst. Land u. Forstw.*, 5 (1906), No. 5, pp. 282-292, figs. 11).—In some localities considerable injuries are reported from the attacks of *Ceutorhynchidius terminatus* and *Phytomyza geniculata*, both of which are described in detail, with notes on their life history.

An insect pest of water cress, C. CATEUR (*Rev. Hort. Belge*, 33 (1907), No. 1, pp. 14, 15).—The larvæ of a fly (*Hydrellia rauunculi*) are reported as mining in the substance of the leaves of water cress, thus ruining their appearance and suitability for table use. No satisfactory remedy has been devised for the pest.

The spring canker worm, H. A. GOSSARD and J. S. HOUSER (*Ohio Sta. Circ.* 65, pp. 7, figs. 8).—The life history of spring canker worm is briefly outlined. In controlling this insect in orchards the fruit grower should depend chiefly on the proper application of bands and spraying with arsenate of lead or Paris green in Bordeaux mixture or in water.

Whitefly conditions in 1906. The use of the fungi, E. W. BERGER (*Florida Sta. Bul.* 88, pp. 49-85, pls. 3).—Parasitic fungi have been widely used in Florida in combating the whitefly. Success was had in 98 per cent of cases from spraying the spores of the fungi on trees or by attaching leaves carrying the fungus to trees. In this work the author used *Aschersonia aleyrodes*, *A. flavo-citrina*, the brown fungus, and *Sphaerostible coccophila*. The spores of the brown fungus have not yet been discovered, hence they can not be used in spraying on the trees. It has been found that in the other species the spores retain their vitality for a month, or perhaps longer.

All of the three first-named species of fungi thrive throughout Florida, but a humid atmosphere is essential for their growth. Apparently the best time for starting the fungi in trees infested with the whitefly is from May to August. Repeated plantings of the fungus should be made to insure success.

In badly infested localities it is recommended that trees along roadways should be trimmed high to avoid the distribution of the whitefly by carriages brushing against the branches. The whitefly feeds on a number of trees, including Cape Jessamin, chinaberry, umbrella tree, prickly ash, trifoliate orange, and others. Where these trees are of no value and infested they should be cut down and burned. If it is desirable to use insecticides against the whitefly, spraying or fumigation should preferably be done from December to February.

The gipsy moth and how to control it, L. O. HOWARD (*U. S. Dept. Agr., Farmers' Bul.* 275, pp. 22, figs. 7).—Historical notes are given on the distribution of the gipsy moth in Europe, its introduction into this country, and its

present distribution. The moth is now known to occur in Massachusetts, New Hampshire, Maine, Rhode Island, and Connecticut.

The insect is described in its different stages and notes are given on its injurious attacks, natural enemies, and artificial remedies. Some of the main features of the present Massachusetts law for the control of the gipsy moth are reproduced and a brief outline is given of the work of the Federal Government in this direction.

The California tussock moth, W. H. VOLCK (*California Sta. Bul. 183*, pp. 189-214, figs. 17).—*Hemrocampa retusta* has been unusually injurious to apple trees in the Pajaro Valley and elsewhere in California during the past few years, especially in 1905. The damage was most severe where the egg masses had not been picked off and destroyed during the previous year. In orchards where this precaution was taken the loss was 23.5 per cent, as compared with 65.6 per cent in untreated orchards.

The pest in question lives on live oak, lupin, apple, and cherry trees as well as other plants. There is one generation annually. The egg masses are laid near buds and the larvæ burrow into the fleshy tissue or the fruit. The only parasites obtained by the author were tachina flies, but the eggs are attacked by a minute parasite.

Preliminary experiments showed that this insect is very resistant to arsenical poisons. The larvæ live for several weeks after feeding on foliage sprayed with arsenate of lead at the rate of 3 to 6 lbs. per 50 gal. of water. On account of the heavy coating of hair the caterpillars are difficult to kill by contact insecticides. Whale-oil soap killed some of them, but kerosene was apparently harmless. The best methods of control seem to be picking off the egg masses as soon as the leaves fall in the autumn and the use of sticky bands about the trunks of infested trees.

The San José scale problem in Ohio, 1906, A. F. BURGESS (*Ohio Dept. Agr., Div. Nursery and Orchard Insp. Bul. 8*, pp. 30, pls. 7, figs. 3).—As a result of his experience with San José scale in Ohio, the author recommends that all infested orchards should be carefully pruned and sprayed before the leaves appear in the spring. For large orchards lime-sulphur wash is considered best and cheapest, while in small city lots or on individual trees proprietary miscible oils give good results.

Report of remedies tested to control the San José scale and the codling moth, 1902 to 1906, A. F. BURGESS (*Ohio Dept. Agr., Div. Nursery and Orchard Insp. Bul. 9*, pp. 36).—Formulas are given for the preparation of the various insecticides which were used in combating San José scale and codling moth and the results obtained in the case of both insects are presented in a tabular form.

The author concludes that lime-sulphur wash made according to the formula 1-1-3 is the most satisfactory and cheapest insecticide which can be used against the San José scale. Thoroughness should be observed, however, in its application in order to protect fruit from becoming spotted with excessive infestation. The longer this treatment is continued the better the results which are obtained.

In spraying for codling moth it was found that the cost per tree averaged about 5 cts. when Bordeaux mixture and arsenate of lead were used in a mixture costing 1½ cts. per gallon. The author believes that the first spraying is the most important and the late July spraying next in importance. Little difference was observed in the effectiveness of the arsenical poison whether Bordeaux mixture was added or not. Arsenate of lead is considered more satisfactory than Paris green.

The value of ladybird larvæ, P. BOEKER (*Arb. K. Biol. Anst. Land u. Forstw., 5* (1906), No. 5, p. 282).—*Coccinella septempunctata* was fed on plant

lice. It was found that during a period of 10 days each larva ate on an average 267 plant lice daily.

A fungus parasite of orange scale, L. TRABUT (*Bul. Agr. Algérie et Tunisie*, 13 (1907), No. 2, pp. 32, 33).—An examination of diseased orange scales showed the presence of a number of parasitic fungi, among which was one which the author describes as new, under the name *Microcera parlatoria*.

The occurrence of Tomicus dispar on apple trees, G. HUSSEN (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser.*, 5 (1907), No. 2, pp. 14-18, figs. 2).—Attention is called to a number of cases in which the attacks of this insect caused the death of infested trees. In such cases small holes were observed in the bark from the larger branches down to the base of the trunk. In combating this pest the author recommends the removal and destruction of infested branches and the planting of oak trees for trapping female beetles.

Acariosis of grapes, G. SCALIA (*Acarosi della Vite, Catania: Monaco & Mollica*, 1906, pp. 15).—A disease of grapes is described in which the berries when nearly mature show a dirty white or grayish color and are covered with minute incrustations of a greenish or brownish color.

An examination of diseased grape berries showed the presence of a mite which was identified as *Glycyphagus spinipes*. This mite is described and notes are given on its biology. Since the mite may be found at some seasons of the year in the bark of the grapevine, it is suggested that all cuttings used for grafting should be scraped and treated if they are suspected of being infested and that infested trunks be treated with extract of tobacco or some similar insecticide.

Insects attacking the wood of grapevines, V. MAYET (*Rev. Vit.*, 27 (1907), Nos. 681, pp. 8-11; 682, pp. 36-40; 683, pp. 63-67; 684, pp. 98-102; 687, pp. 179-185, figs. 17).—This is a practical article prepared for the use of vineyardists in combating insects which attack the stems of grapevines by boring or otherwise injuring them. The insects discussed in the article include species of Cicada, Cossus, white ants, tree crickets, Clytus, Agrilus, Apate, etc. Each species is described and notes are given on its habit and life history.

Bark beetles, O. NÜSSLIN (*Verhandl. Naturw. Ver. Karlsruhe*, 19 (1905-6), pp. 49-64).—A description is presented of the habits of some of the species of bark beetles with notes on their life history and the injury caused by their operations.

The generations of bark beetles, E. KNOCHE (*Ztschr. Forst u. Jagdw.*, 39 (1907), No. 1, pp. 49-53).—The factors which influence the length of the life cycle of bark beetles are discussed with particular reference to *Tomicus typographus*.

Some insects injurious to forests. Additional data on the locust borer, A. D. HOPKINS (*U. S. Dept. Agr., Bur. Ent. Bul.* 58, pt. 3, pp. 31-40).—This is a partial revision of part 1 of Bulletin 58 (E. S. R., 18, p. 159).

On the life history of Termes gestroi, E. P. STEBBING (*Indian Forester*, 33 (1907), No. 1, pp. 6-12, pls. 2).—*Termes gestroi* is proving to be a serious pest of the Hevea rubber tree. It appears that the white ants burrow under ground from one infested tree to another, producing tunnels through the trunk of the tree and hollowing it out from the crown of the root to a height of 7 ft. or more. In cases where an attack is made upon the bark from the outside, the surface of the trunk does not become covered with rubber as would perhaps be expected. On this account the author believes that the ants either eat or carry away the latex which exudes into their tunnels.

The utilization of cockchafers, K. ECKSTEIN (*Ztschr. Forst u. Jagdw.*, 39 (1907), No. 1, pp. 44-49).—In some localities where school children receive a small bounty for the collection of cockchafers, these insects have been collected

in enormous quantities and some attention has been given to their profitable utilization. It appears that they may be used for fertilizer, as a feed stuff, or in the preparation of axle grease.

Insecticides and fungicides, R. HARCOURT and H. L. FULMER (*Ontario Dept. Agr. Bul. 154*, pp. 32).—The purposes and necessity of spraying are briefly outlined and detailed formulas and explanations are given for the preparation and application of the standard insecticides and fungicides.

The lime-sulphur-salt wash and its substitutes, J. K. HAYWOOD (*U. S. Dept. Agr., Bur. Chem. Bul. 101*, pp. 29).—From experiments carried out with chemically pure lime and sulphur, it appears that solid sulphur is not dissolved by boiling 15 minutes, but that the best results are obtained by boiling from 45 to 60 minutes. A boiling period of 1 hour is sufficient to dissolve nearly all of the sulphur, but the thiosulphates are somewhat increased by a longer period.

Salt apparently has no influence upon the composition of the wash in so far as the sulphur compounds are concerned. The slight differences in the composition of the wash, as used by different investigators, have little or no influence upon the time required for boiling. When lime and sulphur are used in equal quantities there is more than enough lime to dissolve the sulphur. These substances may be used in the proportion of 1 lb. of lime to 1½ lbs. of sulphur. About 25 lbs. of sulphur to 50 gal. is a maximum quantity.

It appears that the use of air-slaked lime has no influence on the composition of the wash, and that there is likewise practically no difference in composition whether flowers of sulphur or flour sulphur is used. Detailed notes are also given on the composition of lime-sulphur wash with particular reference to the different kinds of sulphur compounds. It is found that not all of the sulphur is dissolved by the heat generated by caustic soda, but the suggestion is made that a wash containing 10 lbs. of caustic soda and 19 lbs. of sulphur per 50 gal. of water without lime may give satisfactory results.

The use of arsenic in destroying injurious insects, A. RICHIE (*Bul. Agr. Algérie et Tunisie, 13 (1907), No. 1*, pp. 13-22).—As a result of the study of this matter, it is recommended that soluble arsenical compounds should not be employed and that in all cases care should be exercised in the use of arsenicals so that they are prepared and applied in the manner recognized by entomologists and in accordance with laws regulating this subject.

Analyses of Paris green and lead arsenate, G. E. COLBY (*California Sta. Bul. 182*, pp. 177-183).—In 1901 a law was passed in California to prevent fraud in the sale of Paris green. Since that time about 73 tons of Paris green have been examined, of which 7½ tons were rejected. The effect of the law was manifest in the improvement in quality of Paris green bought from New York manufacturers. At first only about 20 per cent of the Paris green was passable and during the fourth year of the operation of the law some laxity in the use of Paris green was again observed. Recently the station has recommended the more extended use of arsenate of lead in the place of Paris green.

The chemical test made at the station comprises the determination of the total arsenic and the quantity of free arsenious oxid. The results obtained by the determination of various samples of Paris green are shown in a tabular form.

Proposed insecticide law, C. W. WOODWORTH (*California Sta. Bul. 182*, pp. 184-186).—In order to bring about further improvement in the quality of Paris green, the text of a proposed law is given worded essentially the same as the law for the control of commercial fertilizers with only such verbal changes as are necessary to make it apply to insecticides.

Animal pests and legislation, F. V. THEOBALD (*Proc. Assoc. Econ. Biol.*, 1 (1906), No. 2, pp. 29-74).—Attention is called to the general recognition of the necessity of legislation for the control of insect pests. Examples are given of insect enemies of crops, animals, and man, and of legislation which has been adopted in controlling these pests. A considerable proportion of the article is occupied with copies of some typical laws relating to injurious insects in England, various English colonies, and in the United States.

First report of the State beekeepers' association of Pennsylvania, H. A. SURFACE (*Penn. Dept. Agr. Bul.* 148, pp. 57, pls. 2).—The Pennsylvania State beekeepers' association was organized in 1904 and held its first annual convention in Harrisburg, December 6 and 7 of the same year. The first annual meeting was held in Harrisburg, December 6-7, 1905, and the present bulletin contains an account of the meeting with copies of some of the papers read. The subjects discussed include the importance of fostering apiculture, the habits of honeybees, foul brood and other diseases, the relation between bees and horticulture, methods of improving honeybees, and notes on honey plants.

Honeycomb, R. PINCOT (*Apiculteur*, 51 (1907), No. 2, pp. 52-60, fig. 1).—The author recommends that every bee raiser should own an apparatus for manufacturing comb foundation and should make his own foundation. In this way considerable expense is avoided and the purity of the foundation can be assured.

Disinfecting mulberry leaves before feeding to silkworms, U. ZANONI (*Bul. Agr. [Milan]*, 41 (1907), No. 2, pp. 1, 2).—Mulberry leaves were fed in a natural state and after disinfection with silver fluorid (1:100,000) or sulphate of copper (1:10,000). It was found during these experiments that while the cocoons of silkworms fed on disinfected leaves weighed slightly more, the amount of available silk was no greater and the advantage of the treatment was, therefore, altogether in favor of the silk raiser.

FOODS—HUMAN NUTRITION.

Food products, A. L. WINTON (*Connecticut State Sta. Rpt.* 1906, pt. 2, pp. 107-166).—Of 2,361 samples of food materials examined, 678 were found to be adulterated or below the standard, 93 were compounds, and 1,457 were not found to be adulterated.

The materials examined included chocolate candy, coffee and coffee substitutes, dairy products, flavoring extracts, cream of tartar, sugar, maple sugar and sirup, culinary fats and oils, sausage and similar goods, oysters and fish, spices and condiments, honey, vinegar, starch, etc.

Two of the 362 samples of milk collected by the station contained borax, 9 samples were watered, and 6 were considerably below the standard and unfit for sale as standard milk. Of the 116 samples collected by health officers, 7 were unquestionably watered, 5 were skimmed, and 47 were below standard. One sample contained formaldehyde.

Twenty-five samples of cream were examined, and of these 1 contained boric acid and 1 was below standard as regards fat content.

Analyses of 8 brands of condensed milk showed that only 4 contained over 28 per cent of solids, or, in other words, had been evaporated sufficiently to conform to the legal standard.

The common adulteration of condensed milk consists in using skimmed milk instead of whole milk for its preparation. Watering of the original milk is a disadvantage to the manufacturer, as it necessitates longer evaporation, and the use of preservatives is unnecessary when the product is thoroughly sterilized

and packed in hermetically sealed cans, although they might serve to keep the milk previous to evaporation or after opening the cans."

Of 16 samples of "butter" tested, 3 were natural butter, 3 renovated butter, and 10 oleomargarine or butterine.

Two culinary fats which purported to be corn products were found to contain cotton-seed oil, "but the characteristic constituent appears to be corn (maize) oil stiffened with a harder fat, such as stearin."

Forty-three of the 135 samples of lard examined were compound and 3 were thus marked.

In the case of olive oil, 14 of the 110 samples examined were adulterated and 2 were compounds. Eleven samples consisting of cotton-seed oil "were labeled salad oil, and are therefore technically compounds."

Tests for preservatives in 88 samples of pork sausage showed that 40 contained boric acid or borax and 36 sulphurous acid. Borax was not found in any of the 21 samples of Hamburg steak examined, but 12 samples contained sulphurous acid. Only one of the 19 samples of oysters examined contained boric acid, but this preservative was found in 14 of the 16 samples of codfish submitted to the station.

A special study was made of diabetic foods, including flours and meals, bread, biscuits, rusks, etc.; nut butter and similar goods; diabetic cocoa and baking powder; macaroni; homemade gluten meal biscuit; and soy-bean biscuit. All of the commercial wheat preparations contained a certain amount of starch, although in most of them the normal percentage was considerably reduced. "The beneficial results from their use is not due solely to the reduced percentage of starch, but also to the increased percentage of protein." The percentage of protein in nearly every case was found to fulfill the claims made by the manufacturers.

"A safe flour for those suffering with the disease is casein flour entirely free from carbohydrates or else a vegetable flour containing the smallest possible amount of these substances, such as may be prepared from soja beans by simply grinding with removal of the hulls, from almonds and other starch-free nuts after expressing a portion of the fat, or from wheat after washing sufficiently to remove nearly all the starch. A guaranty as to protein and starch content should be furnished with each product, so that physicians can calculate dietaries for their patients."

A number of the special diabetic foods did not show any very decided advantage over ordinary wheat flour for diabetic patients when judged by analysis, and microscopical examination "proved that all of them contained large amounts of wheat starch with no marked difference from that of wheat flour."

"In making out dietaries for diabetic patients it should be borne in mind that starch, sugar, and dextrin are all about equally injurious, since starch and dextrin are converted by the saliva and pancreatic juice into sugar (chiefly maltose), and it is the sugar, not the starch itself, which is directly injurious. For example, changing a portion of the starch into dextrin, as is done to some extent by toasting bread, does not render it less injurious, in fact it actually hastens the formation of sugar through the action of the digestive juices, since dextrins are intermediate products in the change. For this reason the sum of the percentages of starch, sugar, and dextrin, and not the starch alone, should be considered in valuing diabetic preparations."

"The peanut, another leguminous seed, although very rich in oil, contains about 11 per cent of starch, sugar, and dextrin, of which about half is starch.

"Most of the nuts, including walnuts, Brazil nuts, almonds, and filberts, since they contain no starch and only small amounts of sugar and dextrin,

but are rich in protein and oil, are valuable additions to the diet of diabetics. Almond meal is used in the preparation of various biscuits and bread substitutes. The chestnut is a notable exception among nuts, in that it is rich in starch and poor in fat, the composition of the shelled nut being much the same as that of wheat flour; it is therefore entirely unsuited for the use of diabetics."

Food legislation during the year ended June 30, 1906, W. D. BIGELOW (*U. S. Dept. Agr., Bur. Chem. Bul. 104, pp. 53*).—This summary of legislation on food in the different States and Territories supplements the compilation of such data previously referred to (*E. S. R., 17, p. 891*).

Foreign trade practices in the manufacture and exportation of alcoholic beverages and canned goods, H. W. WILEY (*U. S. Dept. Agr., Bur. Chem. Bul. 102, pp. 45, pls. 2, figs. 5*).—The author visited some of the principal regions in Great Britain and Ireland, Germany, and France where whisky, wine, and brandy are produced, and some of the French vegetable and sardine canneries, with the special object of securing data on the preparation, preservation, and character of the products mentioned, as offered for importation into the United States, in order that just and effective standards might be adopted for their inspection on arrival at American ports.

As regards the preparation of canned sardines, it was found that it is customary in French canneries to heat the fish in peanut oil previous to packing in olive oil. This is regarded as one of the reasons why peanut oil has been discovered in so many packages of sardines which were labeled "Packed in pure olive oil." "There is no objection to the use of peanut oil for the purpose mentioned, but where the packages are labeled 'Packed in pure olive oil,' it is held that peanut oil should not occur, or at least only in mere traces."

The new meat inspection law and its bearing upon the production and handling of meats, G. P. McCABE (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 101, pp. 16*).—In an address delivered before the New York State Breeders' Association at Syracuse the author discussed the principal provisions of the United States meat inspection law, the manner in which the provisions are enforced, and the bearing of the law upon the production and handling of meats.

"To secure the best results, the breeders and feeders of every State in the Union should take up vigorously the question of the extension of markets and should back the Department of Agriculture in an insistent demand for an absolutely efficient, vigilant, fair, and square meat inspection. . . . If a due regard be had for cleanliness, decency, and honesty in the preparation and marketing of our meat products, the United States will continue to lead the world in the live stock and meat trade."

Concerning meat extract, E. BAUR and H. BARSCHALL (*Arb. K. Gsndhtsamtl., 24 (1906), No. 3, pp. 552-575*).—Among the conclusions drawn from the investigations reported were the following:

Succinic acid is a normal constituent of meat extract and its presence does not depend upon the action of an acid. Small quantities of aspartic acid and grape sugar, when heated in an autoclave, were found to yield succinic acid, and apparently aspartic acid may be looked upon as the source of succinic acid in meat extract. At any rate, succinic acid in meat extract is not due to decomposition.

By means of Jaffé's reaction, creatin and creatinin may be determined quantitatively in meat extract and peptones. Amino acids are present in meat extract, and peptones and determinations are reported of the creatin, creatinin, and amino acids in a number of commercial products.

The hydrolysis of meat extract, II, K. MICKO (*Ztschr. Untersuch. Nahr. u. Genussmitl., 11 (1906), No. 12, pp. 705-729*).—The principal body identified was glutamic acid, and in addition alanin, glycolucin, aspartic acid, and glycocoll,

as well as other amino-acids which it is not possible to identify. (See also E. S. R., 17, p. 683.)

Concerning crab extract, I, D. ACKERMANN and F. KUTSCHER (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 13 (1907), No. 4, pp. 180-184).—The authors have identified considerable amounts of tyrosin, leucin, arginin, and lysin in crab extract. No creatin and creatinin were found, and in general it appears to be the case that these bodies are not present in flesh extractives at the same time as arginin and lysin.

Crab extract, A. RÖHRIG (*Ber. Chem. Untersuch. Anst. Leipsic*, 1905, p. 11; *abs. in Ztschr. Untersuch. Nahr. u. Genussmit.*, 12 (1906), No. 9, pp. 559, 560).—An analysis of commercial crab extract is reported.

Sardine paste, P. BUTTENBERG and W. STÜBER (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 12 (1906), No. 6, pp. 340-344).—Analyses were made of sardine paste, anchovy, and similar goods with a view to securing data for judging the purity of such products.

Concerning the composition of goose eggs, A. SEGIN (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 12 (1906), No. 3, pp. 165-167).—Data are given regarding the weight of the entire egg—yolk, white, and shell—as well as the proportion of ether extract, protein, and phosphorus constituents in goose eggs. According to the author, the data show that the total phosphoric acid and lecithin phosphoric acid in goose-egg yolk is somewhat smaller than in the case of hen and duck eggs. The proportion of free lecithin is about midway between that in the hen's and the duck's egg. The proportion of lecithin in combination is somewhat higher than in the duck's egg and lower than in the hen's egg.

Studies of gelatin and glue, P. BUTTENBERG and W. STÜBER (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 12 (1906), No. 7, pp. 498, 499).—Determinations of the sulphurous and sulphuric acid in a number of samples of gelatin and glue are reported. Apparently all the samples of powdered and sheet gelatin had been treated with sulphurous acid in the process of manufacture, as they contained sulphurous and sulphuric acid. Carpenters' glue, on the other hand, was free from sulphurous acid and contained only a little sulphuric acid.

The investigations were undertaken with a view to securing data regarding the estimation of added gelatin in canned goods.

The food value of vegetable gelatins (*Jour. Amer. Med. Assoc.*, 48 (1907), No. 2, pp. 142, 143).—A summary of data on the use as food of Iceland moss, Irish moss, agar-agar, and Japanese algae.

It is pointed out that jellies and other dishes made from these materials are often used in invalid dietetics and in other ways, and are commonly assumed to have a high food value. According to the data summarized, the carbohydrates, the chief food constituents which they contain, are not digested by man, and so they have little or no nutritive value.

"On account of their marked property of holding large quantities of water, relatively small quantities of vegetable jellies cause the elimination of copious watery feces. As they form agreeable articles of diet when used like gelatin as a vehicle for fruit juices and other flavors, it is suggested that agar-agar or the moss jellies may be of value in certain cases of constipation."

Concerning the manufacture and composition of Chinese bean cheese (Teou-Fou) from Soja hispida, Bloch (*Bul. Sci. Pharmacol.*, 13 (1906), pp. 138-143; *abs. in Ztschr. Untersuch. Nahr. u. Genussmit.*, 12 (1906), No. 9, pp. 564, 565).—The method of manufacturing soy-bean cheese in China is described.

After soaking for 8 or 10 hours the beans are ground, rubbed up with water, and pressed. The resulting liquid is strained through cloth and slowly heated to the boiling point. The bean cheese is then precipitated, pressed, and cut into

small cakes. It is stated that 6 kg. of soy beans will yield 80 liters of liquid, from which 20 to 25 kg. of bean cheese may be precipitated. The pressed cake from this quantity of beans would weigh 13 kg., and is generally used as cattle fodder, though it is not infrequently eaten by poor people.

According to analyses the bean cheese contained 83.85 per cent water, 1.296 per cent nitrogen, 4.33 per cent fat, and 0.57 per cent ash, and the pressed cake 88.75 per cent water, 0.248 per cent nitrogen, 0.04 per cent fat, and 0.36 per cent ash.

Banana flour, A. RÖHRIG (*Ber. Chem. Untersuch. Anst. Leipzig, 1905, p. 31; abs. in Ztschr. Untersuch. Nahr. u. Genussmitl., 12 (1906), No. 9, p. 564*).—An analysis is reported of banana flour from Central or South America.

The fat of sorghum seed, N. ANDREJEW (*Vyestnik Shirov. Veshch., 4 (1903), pp. 186-188; abs. in Ztschr. Untersuch. Nahr. u. Genussmitl., 10 (1906), No. 12, p. 617*).—A study of the fat of *Sorghum ceruum* was made, this seed, in the author's opinion, being a satisfactory food for both man and animals.

Sorghum-seed fat is yellowish in color and not unlike yellow vaseline in appearance, but of somewhat harder consistency. Oleic, reisimoleic, linoleic, and erucic acid were the principal acids present. It resembles oat fat in its combination of erucic acid with oleic acid, and maize fat in that linoleic acid is present. The latter acid accounts for the slow drying properties observed in sorghum-seed fat and the proneness of the meal to fermentation. Valeric, formic, and other volatile fatty acids were identified.

The melting point of sorghum fat is 39 to 40 degrees; the iodine number and other constants are reported.

Chinese bean oil, W. KORENTSCHEWSKI and A. ZIMMERMANN (*Vyestnik Obshch. Hig., 5 (1905), pp. 690-693; abs. in Ztschr. Untersuch. Nahr. u. Genussmitl., 10 (1906), No. 12, p. 616*).—As shown by studies of 4 samples of Chinese soy-bean oil, which is much used in the Orient as a food material, the melting point is 20 to 21 degrees and the saponification number 207.9 to 212.6. Other constants are reported. The samples examined were all liquid, dark brown in color, and resembled plant oils in flavor.

The digestibility was studied with 3 soldiers, 100 gm. being taken per man per day in addition to the regular ration with about 46 gm. of other fat. The coefficient of digestibility was 95 per cent in round numbers. The conclusion was reached that fresh Chinese bean oil is very thoroughly assimilated.

Cocoa and chocolate, H. BECKURTS (*Arch. Pharm., 244 (1906), No. 7, pp. 486-516*).—With a view to the establishment of standards for cocoa and chocolate available data are summarized and discussed. Among the recommendations which were made are the following:

Cocoa mass, cocoa powder, cocoa with the fat removed, soluble cocoa, and similar products, according to the author, should contain no foreign plant substances, as starch of flour, and no foreign mineral matter or fat, and cocoa shells should be removed as far as possible. The cocoa mass should contain on an average 52 to 56 per cent fat and 3 to 5 per cent ash.

Chocolate should not contain added materials with the exception of flavoring matter. If the sugar content is over 66.5 per cent, chocolate should be declared "very sweet." The recommendations also take into account the use of chocolate in confectionery and in the preparation of dietetic articles and medicines.

The pentose content of cocoa beans and its relation to the detection of shell in ground cocoa, H. LÜHRIG and A. SEGIN (*Ztschr. Untersuch. Nahr. u. Genussmitl., 12 (1906), No. 3, pp. 161-164*).—The experimental data led the authors to conclude that more information is needed before variations in the

pentose content can be relied upon for the detection of adulteration of powdered cocoa with cocoa shells.

The proportion of caffenin in coffee and its estimation, P. WÄNTIG (*Arch. K. Gesundheitsamt.*, 23 (1906), pp. 315-332; *abs. in Ztschr. Untersuch. Nahr. u. Genussmitt.*, 12 (1906), No. 7, p. 430).—According to the data reported, a cup of coffee measuring 150 cc. made with 300 gm. of water and 15 gm. very finely ground coffee contains, on an average, from 0.06 to 0.1 gm. caffenin.

Concerning the sugars in spices. I, White cinnamon, J. HANUŠ and F. BEIN (*Ztschr. Untersuch. Nahr. u. Genussmitt.*, 12 (1906), No. 7, pp. 395-407).—The conclusions which were drawn follow:

The pentosan content of spices is fairly constant and depends upon the portion of the plant from which the spice is obtained. White cinnamon contains a larger amount of pentosans than spices obtained from the whole plant or from leaves. In accordance with the results of early investigators, mannite was identified in the spice studied. Arabin and galactan, as well as small quantities of xylan, were dissolved by water under pressure. The insoluble portion of the spice contained xylan and probably glycosan.

Concerning spices. II, Allspice, cloves, and cardamom, R. THAMM (*Ztschr. Untersuch. Nahr. u. Genussmitt.*, 12 (1906), No. 3, pp. 168-172).—Special studies of the ash constituent of spices are reported, particularly the degree of alkalinity of the ash.

Notes on pepper, C. HARTWICH (*Ztschr. Untersuch. Nahr. u. Genussmitt.*, 12 (1906), No. 9, pp. 521-530, figs. 4).—Determinations of the weight of pepper berries are given, as well as notes accompanied by drawings regarding pepper adulterants.

Discoloration of fruits and vegetables put up in tin, F. A. NORTON (*Jour. Amer. Chem. Soc.*, 28 (1906), No. 10, pp. 1563-1568).—According to the author, the discoloration often observed on the can or can contents when fruits and vegetables are preserved in tin is due to the action of sulphids on the heavy metals. If the foods decompose in the can hydrogen sulphid may be liberated from protein by the action of the micro-organisms. Laboratory experiments showed that it may also be produced from food proteids by the action of heat under pressure. The use of an excess of flux in soldering or a poor grade of solder is likewise a condition which favors discoloration, as the action of the fruit or vegetable juice is thereby increased.

"Sulphites should not be used with goods of an acid character which are to be put up in tin. Where a heavy process is necessary, care should be exercised to avoid the use of an excess of flux or the use of low-grade solder or tin plate, which would tend to increase the amount of heavy metals taken up by the goods. Also the length of the process, in order to avoid evolution of hydrogen sulphid, should be as short as possible, consistent with complete sterilization of the goods."

The presence of formalin in foods, G. PERRIER (*Compt. Rend. Acad. Sci. [Paris]*, 143 (1906), No. 17, pp. 600-603).—The possible occurrence of formalin in smoked food products is pointed out and determinations reported of the amount present in a number of products; for instance, 0.03 to 1.20 mg. was found per 100 gm. in ham and 0.04 to 0.6 mg. per 100 gm. in smoked sausage. The necessity of taking into account in pure-food legislation the occurrence of formalin under such circumstances is pointed out.

Food of the natives of India, G. H. FINK (*Jour. Trop. Med. [London]*, 9 (1906), No. 20, pp. 310-312).—On the basis of experience the author discusses the diet of the native population in different parts of India. The high esteem in which milk is held by the native population and the importance of sugar in

the diet are among the questions spoken of. He states that milk boiled for a considerable time and sweetened with large quantities of either white or brown sugar is much used, as well as sour milk, cream, curds, and clarified butter.

According to the author, "it is erroneous to suppose that the whole of the natives of India are vegetarians, in the strictest sense of the term. This idea seems to have gained acceptance from the fact that the wants of the natives, chiefly the Hindoo population, are few and simple, and that they confine themselves to the actual necessities of life in the matter of food."

The Mahomedans "consume more flesh than the Hindoos, and are permitted to eat either fish, fowl, mutton, or beef. Even the poorer class of Mahomedans eat more animal food than the Hindoos, but in some parts of India Hindoos are quite as strong on animal food (mutton and fish) as Mahomedans. The strictest vegetarians are the Jains, a sect of which a great many of the mercantile caste of Upper India are members."

"If we analyze the various kinds of food in use in India by the rich as well as the poor, we can not help coming to the conclusion that, on the whole, the food is fairly well balanced in the matter of the elementary principles of the diet of both Hindoos and Mahomedans. The Hindoos, though largely vegetarians, live on food rich in carbohydrates and hydrocarbons, but they are at the same time large consumers of milk and those products of milk which are healthful and nourishing [as well as legumes, particularly lentils. Fish and mutton are also eaten by the Hindoos]. In Bengal and Assam, fish supplies largely the nitrogenous element, while in other parts of India fish and mutton are used. The Mahomedans, who form about the fifth of the total population of India, live on very similar food to the Hindoos; eat less sweetmeats, but more animal food (mutton, beef, and goat's flesh). Their food, on the whole, contains a larger proportion of the nitrogenous principle than that of the Hindoos."

A number of the sects are not considered in this paper because the author states that their diet conforms more closely to western standards.

Studies of the development of the proletariat in North America, W. SOMBART (*Arch. Sozialwiss. u. Sozialpolitik*, 21 (1905), pp. 556-611; *abs. in Hyg. Rundschau*, 16 (1906), No. 21, pp. 1204-1206).—Considerable attention is devoted in this article to the food of workingmen's families in America, and a comparison is made between the kind and amount of food eaten in America and elsewhere. In the author's opinion, the American workingman lives better than the German.

Diet in boarding schools, J. O. SYMES (*Jour. Roy. Sanit. Inst.*, 27 (1907), No. 12, pp. 767-771).—The subject is discussed with special reference to conditions in Great Britain. The author insists upon the need of an abundant diet of palatable well-cooked food.

"Digestion depends chiefly upon appetite, and appetite is excited by the organs of sight and smell, and by pleasant mental impressions. It is important, therefore, that food at school should be cooked carefully and served daintily. There should be as little as possible of routine in school fare, and everything should be done to discourage children rushing their meals in order to get to work or to play."

Suggestions are made regarding the character of the different meals and related matters.

Studies of children on a vegetarian diet, H. ECKHARDT (*Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, u. scr.*, 1 (1906), No. 20, pp. 617-622).—The studies were made at a so-called vegetarian home in Breslau. The diet, more

properly speaking, should be called lacto-vegetarian, as milk, butter, cheese, eggs, and honey were eaten as well as vegetable foods.

In addition to dietary studies with 3 children from 5 to 7 years old, the balance of income and outgo of nitrogen was determined. In the first two tests there were gains of 2.23 and 1.56 gm. nitrogen per day on a diet furnishing respectively 8.97 and 5.36 gm. of nitrogen. The energy supplied per kilogram per day was 104.6 and 100 calories respectively. In later tests there were gains of 0.47 and 0.65 gm. nitrogen per day respectively on an income of 4.70 and 5.30 gm. The energy supplied per kilogram per day was 70.8 and 89.2 calories.

As pointed out by the author, the diet supplied at the institution did not differ materially from the so-called mixed diet of the region, and was, indeed, doubtless more generous, as most of the working people live on vegetable foods, with some milk, and very seldom have meat.

The results are discussed in comparison with those obtained by other investigators.

A dietary study of five halls of residence for students in Edinburgh, I. D. CAMERON (*Proc. Roy. Soc. Edinb.*, 26 (1905-6), No. 5, pp. 327-351).—The dietary studies were made in 4 men's clubs and 1 woman's club and were each of 1 week's duration, a total of 119 men and 60 women being included.

The diet on an average supplied 143 gm. protein, 138 gm. fat, and 511 gm. carbohydrates, the fuel value being 3,979 calories. The average cost of the food per man per day was 30 cts. Animal protein constituted 63 per cent of the total and animal food made up 66 per cent of the entire cost. The waste varied considerably, its approximate cost being from 2.4 per cent to 7 per cent of the total sum expended for food.

Metabolism on insufficient diet, I-IV, F. N. SCHULZ, E. MANGOLD, H. STÜBEL, and E. HEMPEL (*Arch. Physiol. [Pflüger]*, 114 (1906), No. 9-10, pp. 419-486, fig. 1).—Investigations carried on by Schulz's students are reported and summarized. The principal conclusions follow:

The experimental data furnish additional demonstration of the fact that the organism of a fasting dog can lose so much fat that the metabolism of protein is increased. On insufficient diet the total metabolism may be reduced to half the normal. Fasting induces disturbances which can not be attributed to a lack of energy-yielding food or to the fact that no more body protein can be spared, but which are apparently caused by a kind of auto-infection. These disturbances disappeared when a small amount of food was supplied.

Additional experiments are needed to study the many conditions which affect nitrogen metabolism in fasting.

Problems in animal metabolism, J. B. LEATHES (*London: John Murray, 1906, pp. 205; rev. in Pub. Health [London]*, 19 (1907), No. 5, p. 327).—This course of lectures, delivered at London University, summarizes recent investigations and older work in metabolism and discusses available data with reference to various problems concerned with health and disease.

The effect of consuming different amounts of calcium and magnesium upon the metabolism of these constituents and the quantities present in the animal body, S. GOTTIEN (*Arch. Physiol. [Pflüger]*, 115 (1906), No. 1-2, pp. 118-151).—According to the investigations (which were made with rabbits) an abundance of calcium and magnesium in the diet induces a storage of these constituents in the body while a deficiency of calcium and magnesium lowers the body store. The changes are especially noticeable in bones and the muscular system. The variations in magnesium content of the other organs is particularly small.

The value of resistant or negative work in animal dynamics, J. LEFÈVRE (*Compt. Rend. Acad. Sci. [Paris]*, 143 (1906), No. 20, pp. 757-760).—The author discusses resistant or negative work—that is, the work expended—for instance, in walking downstairs as compared with positive work or that expended in walking upstairs. According to his calculations, this negative work is equal to one-half of the corresponding positive work.

Lessons on elementary hygiene and sanitation with special reference to the Tropics, W. J. PROUT (*London: Waterlow & Sons, 1905, pp. 159, illus.; rev. in Brit. Med. Jour., 1906, No. 2406, p. 322*).—In this volume, which was printed for the colony of Sierra Leone, water, food, dwellings, and personal sanitation are among the topics considered.

The hygiene of the intestines, E. METCHNIKOFF (*Rev. Gén. Sci.*, 17 (1906), No. 20, pp. 899-906).—The dangers which may result from the passage of bacteria through the intestinal walls and from the presence of bacteria and parasites in the intestines are pointed out and the importance of sterile and clean food insisted upon. Special reference is made to the dangers which may attend the use of uncooked vegetables, fruit, oysters, and other food materials.

Putrefactive fermentation in the intestine, R. BAUMSTARK and L. MOHR (*Ztschr. Expt. Path. u. Ther.*, 3 (1906), No. 3, pp. 687-690).—According to the observations reported, putrefactive processes, as shown by the excretion of ethyl-sulphuric acid and indican, continue in fasting as long as hunger feces are retained in the intestine. After the excretion of such feces no indican was found in the urine. This is an additional proof that indol formed in the intestine is the sole source of renal indican and that it is not formed by the cleavage of body protein during fasting.

Estimating the specific gravity of feces, H. STRAUSS (*Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, u. ser.*, 2 (1907), No. 2, pp. 49-52).—A pycnometer suitable for use in determining the specific gravity of feces is described and the method of making such determinations outlined.

ANIMAL PRODUCTION.

Commercial feeding-stuffs (*Die Futtermittel des Handels. Berlin: Paul Parey, 1906, pp. VIII+1191, pls. 29, figs. 135*).—This volume comprises papers by a number of authors summarizing available data on composition, digestibility, adulteration, and related questions with reference to the principal commercial feeding stuffs. These papers are reprinted from *Die Landwirtschaftlichen Versuchs-Stationen* for 1900 and later, and have been noted as they have appeared. The volume contains a preface by O. Kellner and an index compiled by M. P. Neumann.

Commercial feeding stuffs, E. H. JENKINS and A. L. WINTON (*Connecticut State Sta. Rpt. 1906, pt. 3, pp. 169-218*).—The feeding stuffs examined under the State law included cotton-seed meal, cotton-seed feed, linseed meal, rape-seed meal, entire wheat meal, wheat bran, wheat middlings, mixed wheat feed, maize meal, gluten feed, hominy feed, rye feed, ground oats, buckwheat middlings, malt sprouts, gluten feed, dried distillers' grains, dried brewers' grains, miscellaneous mixed and proprietary feeds, special poultry feeds, meat scrap and ground bone, condimental cattle feed, corn silage, and corn for ensiling.

As a whole, the results show fewer discrepancies between guaranteed and actual composition than formerly, and the authors state there seems little evidence of any desire on the part of the manufacturers to deceive the public regarding the quality of feed.

“There are, however, a good many feeds offered for sale . . . which could

not be sold to feeders who apply a fair knowledge of the art of feeding stock and business methods to the buying of their feed."

The buyer should study the market price and composition of commercial feeds and make his selection accordingly.

"Cotton and linseed meals, the gluten and wheat feeds, distillery and brewers' grains, and a few other standard things supply digestible protein at reasonable prices. They are all that any feeder needs to supplement and balance the hay, silage, stover, and corn meal which his farm produces. They are the only commercial feeds which will supplement them. It is absolutely impossible to balance the feed which the farm produces with boughten feed containing less than 15 per cent of protein, which is more than many of these commercial feeds contain. On a well-managed farm there is no need to buy starchy feeds nor a single oat hull nor any chaff."

The substituting value of different feeding stuffs, L. DUCLERT (*Bul. Mens. Off. Renseig. Agr. [Paris], 5 (1906), No. 12, pp. 1488-1494*).—The author has calculated and arranged in tabular form data which show amounts of different feeding stuffs equivalent in nutritive value, with special reference to the feeding of horses and ruminants.

Feeding cellulose and coarse fodders to herbivorous animals, V. P. VSTYANTZEV (*O Pitanii Trarogradnuikh Zhivotnuikh Klychetkoi i Ghrubnii Kormami. Kiev: 1906, pp. VII+174*).—Experiments with sheep and rabbits were undertaken to determine the feeding value of wheat straw before and after a treatment which would remove a greater or less amount of the incrusting material present. In some of the experiments with rabbits the respiratory products were taken into account, a Pashutin respiration calorimeter being used.

According to the author's summary, winter wheat straw when fed to sheep has a low nutritive value, and when fed to rabbits its value is negative. On the other hand, cellulose from the same straw freed from incrusting substances has a decided food value and is equal to isodynamic quantities of starch and sugar as protectors of protein and fat. When fed to either rabbits or sheep, it is almost completely digested. Even if the incrusting substances are only partially removed the value of the coarse fodder is decidedly increased, but the maximum effect is not obtained unless the fodder is entirely freed from such constituents.—P. FIREMAN.

Investigations on the protein sparing action of asparagin, M. MÜLLER (*Arch. Physiol. [Pflüger], 112 (1906), No. 5-6, pp. 245-291, pls. 3*).—Experiments with bacteria from the paunch of ruminants showed that they select asparagin in preference to protein as nutritive material. The author concludes, therefore, that asparagin serves as a protector to protein and that these bacteria have the power to synthesize nitrogenous bodies of higher molecular structure from asparagin and from ammonium tartrate. The bodies formed give the same reactions as peptone and pure albumen. The author believes that the results noted in vitro are applicable to the animal body.

New experiments on the source of hippuric acid in the animal body, H. VASILIU (*Mitt. Landw. Inst. Breslau, 3 (1906), No. 5, pp. 829-866*).—According to the author's investigations, benzoic acid derived from plant proteids by oxidation is to be regarded as the source of hippuric acid in the animal body. The leaves and fruits contain a larger proportion of the mother substance than stems and roots, and the older the plant the smaller the amount in leaves, stems, and roots. The mother substance is inversely proportional to the crude fiber and pentosan content and directly proportional to the protein content.

Incrusting substances, such as lignin, can not be regarded as the principal

depositories of the hippuric acid yielding material. When a feeding stuff is oxidized benzoic acid is derived chiefly from phenyl alanin. Only a small part of the unhydroxylized benzin of phenyl alanin undergoes cleavage and oxidation in the body in the case of herbivora, and the greater part reappears in the urine as hippuric acid and as phenyl alanin. In the case of man and very probably of carnivorous animals also the reverse is the case, and only a very small amount is excreted in the urine as phenyl alanin. In this case phenyl alanin plays very little part in the formation of hippuric acid. The greater part of the unhydroxylized benzin ring of proteids undergoes cleavage and combustion in the human body and probably in the case of carnivora also, only a small portion being excreted as hippuric acid in the urine or undigested in the feces.

Stable ventilation, purpose, scope, and need for such work, M. H. REYNOLDS and C. C. LAPP (*Minnesota Stu. Bul.* 98, pp. 87-120, figs. 8).—The authors preface the account of their own investigations with a summary of the available data on the subject of stable ventilation and a discussion of the need for work along this line. The investigations reported were undertaken to determine how little air is compatible with normal health and comfort of live stock and with economical feeding in northern climates during midwinter, as obviously the question of stable ventilation during the summer is a matter which requires little consideration.

The experiments reported varied in length from 6 hours to 37 days, and a tightly closed stable of special construction provided with openings through which food and water could be supplied without admitting any appreciable quantity of outside air was used. For purposes of comparison, steers were also kept in an open stall. The amount of carbon dioxid in the air reached as high as 2.67 per cent. Ordinarily when the closed-stall conditions were very bad it would range from 0.52 to 1.09 per cent. Frequently the proportion of carbon dioxid would increase during varying periods to a maximum, and then either remain constant or decrease without added ventilation. The relative humidity of the air varied up to 99 or practical saturation. Moisture would gather freely on the ceiling and walls of the stable and would sometimes run down in small streams. "It is scarcely possible to imagine a stable where more unsanitary conditions according to accepted standards are maintained than in this stall."

Samples of blood and urine were taken for analysis at regular intervals. In the case of the blood the red and white corpuscles were counted and the hemoglobin content, the period of coagulation, and the specific gravity were estimated. Analyses and other studies were made with the urine, but all these analytical data are reserved for further publication.

The results obtained, according to the authors, show the great adaptability of the animal organism, a fact which has been pointed out by earlier investigators.

"The only records materially varying in a long series of averages as between open and closed stall conditions, as stated for the closed stall, were: Pulse slightly increased, respiration slightly increased, average period for blood clotting materially increased. Changes in the red and white blood cell counts were not uniform and the results are given no special significance. . . .

"When animals were confined in a slowly contaminated atmosphere there was no appreciable effect, even though the atmosphere varied very widely from a normal air and contained large proportions of substances which have been supposed to be actively injurious.

"One steer was confined in the closed stall for 37 consecutive days and seemed to be in perfect comfort, showing every symptom of being at ease, and there

were no variations from the normal that could be detected by laboratory and clinical methods used."

The moisture content of the stable air was often excessive.

Tentative conclusions were drawn from the experiments as follows:

"Historical statements concerning the unwholesomeness of badly crowded and unventilated stables are conceded to be in the main correct as to actual facts, but the accepted explanations may be seriously questioned.

"When animals confined in unventilated stables are injuriously affected, it is so because of other conditions and causes than those usually accepted.

"The amount of CO₂ present in any ordinary stable or any probable lack of oxygen is not seriously important.

"The amount of CO₂ present in the atmosphere is a very unreliable guide as to hygienic conditions.

"The mysterious and oft quoted 'organic matter,' if harmful, may be so because it furnishes favorable conditions for disease producing bacteria.

"A well-lighted stable with poor ventilation is superior from a sanitary standpoint to a well ventilated but poorly lighted one, since the injury, if any there be, apparently comes from disease producing bacteria and various other causes rather than from harmful gases.

"The ventilation plans for a stable need not be made with any special consideration for CO₂."

The rational feeding of farm animals, A. CARRÉ (*Jour. Soc. Cent. Agr. Haute-Garonne, 16 (1906), No. 172, pp. 287-345*).—Various questions connected with feeding farm animals are discussed, methods of calculating rations are explained, and other data of a similar nature are summarized.

Feeding whole grain, R. S. SHAW and H. W. NORTON, Jr. (*Michigan Sta. Bul. 242, pp. 59-67*).—The purpose of the experiments reported was to determine the percentage of whole grain passing through the digestive tract and to ascertain if any changes take place in the composition of the grain. No effort was made to compare the feeding value of whole grain and ground grain.

The tests were made with 6 cows, 6 yearling heifers, and 6 6-months-old calves, and lasted 3 weeks. Corn, oats, and a mixture of corn and oats were fed to each animal at different times.

The results are summarized as follows:

Proportion of grains eaten recovered whole in the feces—Experiments with cattle.

	Whole corn recovered.	Whole oats recovered.	Whole corn and oats recovered.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Cows	22.75	12.06	26.46
Heifers	10.77	5.48	17.50
Calves	6.28	2.98	5.78

"Chemical analyses showed practically the same composition of grain as before feeding, therefore it is safe to conclude that the animal derives no benefit from grain which passes through the digestive tract unmasticated.

"The germinating power of the grain passing through the system was affected very markedly, but not entirely destroyed, as 4.3 per cent of the corn and 10.6 per cent of the oats germinated after this treatment."

Cattle feeding experiments, J. A. CRAIG and F. R. MARSHALL (*Texas Sta. Bul. 86, pp. 23, figs. 10*).—In the first of the experiments reported on the value of molasses for fattening cattle a lot of 6 steers fed on an average a daily ration of 14 lbs. of cotton-seed meal and corn chop 1:2 and 12.5 lbs. of cotton-seed hulls

with a full feed of molasses (3.1 qt. per head) made an average daily gain in a 70-day period of 1.71 lbs. at a cost of 10.05 cts. per pound. Similar animals fed the same grain ration but no molasses made an average daily gain of 1.27 lbs. per head at a cost of 11.3 cts. per pound.

In the second test cotton-seed hulls, cotton-seed meal, and corn chop, supplemented by large and small amounts of molasses, were compared with cotton-seed hulls, cotton-seed meal, and corn chop alone, corn chop being added to the rations in the second and third periods. In the last 44 days of the test, which as a whole covered 100 days, alfalfa hay was fed to all the lots in addition to the other feeds and a little molasses was given to the lot which had previously received none. The gains ranged from 1.92 lbs. per head per day in the case of the lot which had received no molasses throughout the greater part of the test to 2.71 lbs. with the lot receiving the full molasses ration. The gain was most cheaply made with the latter lot, costing 4.95 cts. per pound, and was most expensive with the former lot, costing 5.55 cts. per pound.

In a third test feeding molasses from a trough to cattle on grass was studied with 2 lots of 10 steers each. They were given similar rations of cotton-seed hulls, cotton-seed meal, and alfalfa hay. The lot fed molasses ad libitum from a trough was given less corn chop than the other lot. When fully accustomed to the molasses 12 lbs. per head per day were eaten on an average. "Some steers seemed especially fond of the molasses and ate it in such large quantities as to cause them to scour." On the molasses ration the average daily gain in the 60 days of the test was 1.14 lbs. and the cost of a pound of gain 13 cts., as compared with 0.97 lb. at a cost of 12.7 cts. with the lot fed practically no molasses for comparison. "This is the only experience we have had with the system of feeding clear molasses separately."

A test with 3 lots of 10 pigs each is briefly reported in which corn chops alone and with cotton-seed meal and cotton-seed meal and molasses were compared. On the corn chops alone the average daily gain was 0.51 lb. per pig and the cost of a pound of gain 8.14 cts. On corn chops and cotton-seed meal 2:1 the average daily gain during the same period was 0.66 lb. and the cost of a pound of gain 7 cts. On a similar grain ration with molasses added the average daily gain in 43 days was 0.82 lb. per head and the cost of a pound of gain 6.32 cts.

Data on the use of molasses as a horse feed are also summarized.

The conclusions which were drawn regarding the feeding of molasses were in effect as follows: In the tests reported the addition of molasses to a fattening ration for cattle always produced an increased gain and adding molasses to a ration of cotton-seed meal and hulls diminished the cost of gain. When molasses was added to a balanced ration, though the cost was not decreased, larger gains were noted and the appearance of the cattle was improved. No undesirable results were noted when yearling steers were fed a gallon of molasses per head per day, and there is good reason to believe that larger amounts might be used. Molasses returned from 3 to 30 cts. per gallon, the lower value being obtained when it was added to a well-balanced ration and the higher value when it was added to a ration which in the early part of the feeding period was not well balanced.

Rough rice for steer feeding was also studied with 3 lots of 5 animals each, the basal ration consisting of cotton-seed hulls, cotton-seed meal, and alfalfa hay. On the basal ration alone the average daily gain per head, in the 70 days covered by the test, was 1.36 lbs. and the cost of a pound of gain 5.9 cts. When the larger quantities of whole and ground rice were fed the average daily gain was 1.4 lbs. per head and the cost 9.01 cts., and with the smaller ration of whole and ground rice the values were 1.52 lbs. and 7.15 cts.

"With cotton-seed hulls for roughage it required 2.3 lbs. of rough rice to equal 1 lb. of cotton-seed meal in this test. If the rice were charged at \$10 per ton, the gains would cost the same as in the lot eating cotton-seed meal and hulls.

"This is by no means conclusive evidence as to the feeding value of rough rice. Fed with alfalfa, cowpea, or peanut hay, it should be worth more than when fed with cotton-seed hulls. Compared to cotton-seed meal when feeding with hulls it lacks both in composition and the physical qualities which cause meal to be so heartily relished."

Fattening steers on barley and rejected wheat, J. H. SHEPPERD and W. B. RICHARDS (*North Dakota Sta. Bul. 73, pp. 239-258, figs. 2*).—In continuation of earlier work (E. S. R., 10, p. 671), 7 steers were fed ground barley and bran 2:1 with corn fodder and hay (millet, slender wheat grass, and oat hay). In 132 days, the average daily gain was 2.14 lbs., 6.57 lbs. of grain being required per pound of gain. The maximum amount of grain eaten per steer was 20.3 lbs. The average dressed weight was 62.4 per cent of the live weight and the calculated profit was \$7.57 per head.

In the second test, made with 2 lots of 11 steers each a ration of rejected wheat and bran 3:1 was compared with corn meal and bran 3:1, the grain ration being supplemented by hay of inferior grade similar to that mentioned above.

On the wheat ration the average daily gain in the 112 days of the test was 0.7 lb. per head, 17 lbs. of grain being required per pound of gain. On the corn-meal ration similar values were 1.47 lbs. and 8.5 lbs. The cost of a pound of gain in the 2 cases was 12.9 and 8.5 cts., respectively.

"It required 52 per cent more wheat than corn to produce a pound of gain. The difference in the cost per pound of gain was very different because of the difference in the price of the corn and the rejected wheat."

At the close of the test all the steers were fed corn and bran until they were ready for market (7 weeks), the average daily gain of the animals previously fed wheat being 3.08 lbs. per head and of those fed corn 1.5 lbs.

Considering the whole experimental period, the average gains of the 2 lots were 1.42 and 1.47 lbs., respectively, and the cost of a pound of gain 7.5 and 9.3 cts. According to the authors, "rejected wheat and bran will prove unsatisfactory as a ration to finish steers upon."

"The results derived from the 2 feeding periods seem to indicate that rejected wheat and bran would prove as good a grain ration to feed during the first part of the feeding period as corn and bran, and that good gains can be made by feeding corn toward the end of the feeding period. It is difficult to assign a cause for this change of feeds producing such large gains. The extra growth made by the steers in . . . [the lot fed the wheat] may account for the gains made later on. The condition of their systems must have been better for assimilating the new ration."

Both lots were fed at a loss, the amount being \$1.52 per head with the wheat-fed steers and \$5.81 with the corn-fed lot. An analysis of the rejected wheat used is reported.

A plan for the improvement of Michigan cattle, R. S. SHAW (*Michigan Sta. Bul. 241, pp. 35-53, figs. 5*).—It is stated that the present bulletin is intended as a preliminary to reports of investigations on animal breeding now in progress or contemplated at the station. Existing conditions in cattle breeding, the inferiority of the common stock and related questions are discussed and general directions given for the upbreeding of cattle.

The improvement of Michigan cattle, in the author's opinion, necessitates

a knowledge of existing conditions and facts regarding breeding, and would be greatly facilitated by the proper formation of breeders' associations.

Cull beans as a food for swine, R. S. SHAW and A. C. ANDERSON (*Michigan Sta. Bul.* 243, pp. 71-81).—The use of cooked cull beans as a feed for young and growing pigs and for fattening purposes was studied.

When 4 lots of 4 or 5 pigs each, weighing on an average not far from 50 lbs., were fed beans with corn meal 3:4 for 10 weeks the average gain ranged from 0.797 lb. to 1.04 lbs. per head per day, and the cost of a pound of gain from 2.63 cts. to 2.95 cts.

In this and subsequent tests the beans were cooked either in a cauldron by boiling or in a barrel into which live steam was passed. The beans were fed warm, other feed when used being mixed with them after cooking. Sufficient salt was added to make the ration palatable.

As the above-mentioned ration was, in the author's opinion, not well suited to the pigs some middlings were substituted for part of the beans in a test made with 2 lots of 5 pigs, each weighing on an average 73 lbs., the mixture selected being beans, corn meal, and middlings 2:3:2. The average daily gain in the 10 weeks of the trial was 1.34 lbs. per head, and the cost of a pound of gain 3.1 cts.

The average daily gain on sour skim milk and corn meal 5:1, in a control test made with 2 similar lots, was 1.34 lbs., and the cost of a pound of gain 3.7 cts.

Five lots of 4 and 1 lot of 6 animals, weighing about 150 lbs. each at the beginning of the trial were used to test the value of cull beans for fattening pigs, and the results reported are for a period of 8 weeks. Three of the lots were given cooked beans only, and the average gain was 1.1 lbs. per head per day, 4.21 lbs. of beans being consumed per pound of gain, of which the cost was 2.53 cts. In the case of the 3 similar lots on beans and corn meal 1:1 the average daily gain was 1.52 lbs., the cost of feed per pound of gain being 3.25 cts., 2.03 lbs. of beans and an equal quantity of corn meal being required per pound of gain.

"It would appear that hogs of the weights and ages of those fed in this experiment could reasonably be expected to make a gain of about a pound per day on a ration consisting of beans only, and that the same sort of hog could reasonably be expected to make a gain of about 1.5 lbs. per day if an equal amount of corn were supplied with the bean ration. Further, it would appear that the gains made by the bean-fed hogs would cost about \$2.50 per 100 lbs. and those made by the beans and corn fed hogs would cost about \$3.50 per hundredweight," rating corn meal and beans at what were considered fair prices.

When judged by experts as to quality, the pigs fed a ration containing corn meal were rated at a higher value per pound than those fed the beans only.

According to the authors, "beans can be fed to swine only in the cooked form. The pig seems to be unable to utilize beans which are at all hard or firm, even though they have been boiled for some time, hence it is very essential that they should be thoroughly cooked. To supply a single feed of half-cooked beans to a pen of hogs robs them of their appetites and relish for their food, if indeed it does not put them off feed." Sufficient water should be used in cooking to supply the amounts needed by the pigs, but the feed should not be excessively sloppy.

"All refuse grains contain more or less foreign material. Cull beans are no exception to the general rule, perhaps the most objectionable ingredient being the gravel stones. . . . By the use of a hand fanning mill adapted for bean cleaning, a considerable portion of the stones may be eliminated."

"In winter feeding it will be advisable to supply the feed while warm," but

not hot. "Pails should be rinsed after each feeding, and especial care should be taken to clean the kettle or barrel after each cooking and not allow sour or moldy material to collect about the food receptacle."

"Mixed with other grains, cull beans may be fed to sheep, and large quantities are used in this State for this purpose each year; it is reported that they are used as a food for dairy cows; they are also fed to swine.

"While this work was undertaken in an effort to furnish information to a large number of inquiring residents of this State, it is not desired to advocate the extensive use of beans as a swine food, especially in the fattening or finishing period. Pork from hogs which have been fattened quite largely on beans is generally soft and lacking in quality. If a considerable portion of the pork produced in the State were of this kind it would lower prices and work serious harm to the swine industry.

"It is generally conceded that bean-fed hogs store up a fat having a lower melting point, and consequently a softer fat, than hogs fed upon many other feeds; and that a considerable portion of the element called quality in pork is dependent upon the melting point or character of the fat stored up. In the case of mutton finished upon beans no such criticism has been made, probably because there is relatively less fat in the carcass of the sheep, and its character is not so essential to the quality of the meat as in the case of the pig."

Fat pigs, RASQUIN (*Jour. Soc. Agr. Brabant et Hainaut*, 52 (1907), No. 5, pp. 115-117).—In a discussion of marketing pork, brief reference is made to records of data regarding losses in weight and similar topics. In general, the author states that the dressed carcass constitutes, on an average, 80 per cent of the live weight and the internal organs 15 per cent.

The normal temperature of the goat, G. C. C. DAMANT (*Jour. Physiol.*, 35 (1906), No. 1-2, *Proc. Physiol. Soc.*, 1906, p. V).—As shown by the average of 194 measurements of rectal temperature made with 17 goats, the mean body temperature in the morning was 39.75° C. and in the evening 40° C.

First lessons in poultry keeping, J. H. ROBINSON (*Boston: Farm-Poultry Pub. Co.*, 1906, pp. 160, figs. 29, charts 2, dgms. 5).—A second-year course for the home study of poultry keeping. Some of the subjects included are duck, goose, and turkey raising, kinds, breeds, and varieties of fowls, eggs and egg production, winter egg production, and poultrymen's organizations.

Report of poultry division, D. D. HYDE (*New Zeal. Dept. Agr. Ann. Rpt.*, 14 (1906), pp. 121-140, figs. 6).—Brief statements are made regarding the year's work of the poultry department, results of egg-laying competitions, grading and exporting of poultry and eggs, the construction of trap nests, egg carriers, and related matters. Data are also given regarding the departmental poultry stations. In general, "the returns for the year from the 4 poultry-breeding stations show an increase in the number of birds and a decrease in the number of eggs sold for breeding purposes."

Which weighs the most, the egg or the chicken which comes from the egg, C. A. WHITING (*Bul. South. Cal. Acad. Sci.*, 5 (1906), No. 3, pp. 59, 60).—A fertile egg during the process of incubation lost a little over 20 per cent in weight, while a sterile egg receiving the same treatment lost 15.5 per cent. Another fertile egg weighing 62.842 gm. lost during incubation 21.64 per cent in weight. The chick hatched from the egg weighed 44.204 gm., or 29.65 per cent less than the egg before incubation. A fertile egg violently shaken before incubation to destroy the germ lost 17 per cent during incubation.

Frog farming, W. E. MEEHAN (*Penn. Dept. Fisheries Bul.*, 4, pp. 13).—For some years the Pennsylvania department of fisheries has been studying various questions pertaining to frog raising and the present bulletin summarizes data on the subject and may be regarded as a progress report.

According to the author, "frog ponds may be in any waste, marshy land, providing water can be flowed through them, or any land whatever into which water can be introduced from a stream or spring, preferably the former, because of a usually higher temperature." For profitable frog culture the author believes at least 3 acres are required, and this should be divided into about 10 ponds. As the ponds are not all needed at the beginning, their construction may be scattered over a period of 2 years. At the outset a small pond is required for hatching eggs and developing the tadpoles, then ponds are needed for the young frogs and for the 2-year olds and 3-year olds. The ponds must be fenced to prevent the frogs from escaping.

The principal enemies are birds, snakes, eels, fishes, and the larvæ of the water beetle, the latter being especially dangerous.

As regards food, tadpoles will eagerly devour any dead animal matter, but prefer fish. About 25 lbs. of fish per week is sufficient for the needs of 60,000 tadpoles. Fifteen to 20 lbs. of liver would also be sufficient for the same number, but the liver must be fresh. The liver should be fed in small quantities, but the fish may be thrown into the water whole. After the legs develop the quantity of food should be diminished. Fully developed frogs need live feed and insects may be attracted to the ponds by placing boards near the edge smeared with masses of honey, and in similar ways.

Other questions regarding the habits of frogs, feeding, rearing, etc., are also discussed.

DAIRY FARMING—DAIRYING—AGROTECHNY.

Report on further experiments on the feeding of dairy cows at Offerton Hall, C. B. JONES (*Durham County Council, Ed. Com., Offerton Bul. 2, pp. 36*).—This is a continuation of experiments previously noted (*E. S. R., 17, p. 901*).

The feeding of concentrated food on pasture (pp. 5-23).—Ten cows were divided into 2 equal lots, one of which was pastured for 12 weeks without concentrated feed, while the other lot also pastured was fed 4 lbs. of concentrated feed daily during the first half of the experiment and 8 lbs. during the second half. The experiment was repeated 1 year later. The results obtained during the 2 years indicate, according to the author, that with average pasture the advantage of feeding a supplementary grain ration of 4 to 8 lbs. as regards the yield of milk is exceedingly small. The cost of the concentrated feed was out of all proportion to the value of the increase in the yield of milk. The quality of the milk was not appreciably affected. It is, therefore, considered unprofitable to feed cows more than enough food to keep them in a thriving condition.

The effect of brewers' grains on milk (pp. 23-36).—Two experiments are reported, in each of which 2 lots of 5 cows were fed in turn for 8 weeks a daily ration containing 20 lbs. of brewers' grains. The yield of milk was materially increased by the brewers' grains, but the percentage of fat was thought to be slightly reduced during the early part of the lactation period. There was no appreciable effect on the solids-not-fat, in the milk nor on the live weight of the cows.

Grape pomace in the feeding of dairy cows, A. MARESCALCHI (*Coltivatore, 53 (1907), No. 11, pp. 334-337*).—The author discusses the composition and feeding value of grape pomace, concluding that this material may be fed to the extent of 10 kg. per head daily without injury to the health of the animals or unfavorable effects on the milk production.

Remarkable difference in dairy cows, W. J. FRASER (*Illinois Sta. Circ.*

106, pp. 16, figs. 10).—The records of 2 cows at the station are used as the basis for a popular discussion of the importance of testing dairy cows.

The three-year-old milk and butter record, A. L. HAECKER (*Breeder's Gaz.*, 51 (1907), No. 6, p. 281, fig. 1).—This gives 1 year's record of a Holstein cow, beginning when she was 3 years and 1 month old. The yield of milk was 18,573.4 lbs. and of butter fat 620.44. The net profit was estimated at \$156.20.

A contribution to the anatomy and physiology of the mammary gland, F. BERKAY (*Anat. Anz.*, 30 (1907), No. 7-8, pp. 161-180, figs. 7).—The author concludes, as a result of his investigations, that with suitable histological methods the epithelium of the empty or partly filled alveoli appears as simple columnar epithelium, as in other glands. The many variations which have been described are believed to be due to post-mortem changes or to unsuitable fixing and embedding methods. The formation of milk is, therefore, considered a true secretory process and in no manner associated with a total or even partial necrosis of the secreting epithelium. The tall cylindrical epithelial cells of the empty alveoli gradually become cuboidal and finally squamous as the alveoli become filled. A bibliography is appended.

The results of a chemical, microscopical, and bacteriological examination of samples of London milks, R. T. HEWLETT and G. S. BARTON (*Jour. Hyg. [Cambridge]*, 7 (1907), No. 1, pp. 22-31).—Examinations were made of samples of the milk sent to London from 26 counties. The conclusions drawn from the results obtained are as follows:

"There is no correlation between poor milk and its content of total bacteria, *Bacillus coli* or *B. enteritidis sporogenes*. There is no correlation between the content of *B. coli* and of *B. enteritidis sporogenes*. The total number of organisms was below 2,000,000 per cc. in 22 out of the 26 samples (85 per cent) and below 1,000,000 in 16 of the samples (61.5 per cent). *B. coli* was found in 46 per cent of the samples, in a quantity of milk not exceeding 1 cc. *B. enteritidis sporogenes* was found in 60 per cent in a quantity of milk not exceeding 20 cc. Preservatives in the form of formalin, or boric acid, or borates, were not detected in any sample. The acidity on the whole is well below Newman's standard [22 cc. tenth normal sodium hydroxid per 50 cc. of milk]. *B. tuberculosis* was not so frequent as might have been expected from the results of other investigators."

The ferments of milk, C. BRAHM (*Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, n. ser.*, 2 (1907), Nos. 3, pp. 81-86; 4, pp. 129-132).—This article summarizes information concerning the different enzymes which have been reported as occurring in milk.

Influence of the Bulgarian ferment on milk, G. BERTRAND and G. WEISWEILLER (*Liebig's Ann. Chem.*, 351 (1907), pp. 486-503).—The authors investigated the ferment used in the preparation of the Bulgarian milk product known as Yoghurt. This organism is considered the most active of those which convert milk sugar into lactic acid.

According to the conclusions reached, this ferment renders about 0.1 of the casein soluble, but uses only a very small part of this for its own growth. It causes a very slight saponification of the fat. The action of the ferment upon milk sugar is, however, very vigorous, and with the aid of a lactase converts practically all of the milk sugar into a mixture of levulo and dextro-rotary lactic acids, of which the latter predominates. The quantity of lactic acid may reach 25 gm. per liter. There is also about 0.5 gm. per liter of succinic acid and about the same quantity of acetic acid. A very small quantity of formic acid is also probably present. This ferment is considered the first typical lactic-acid ferment known to produce succinic acid and also the first to hydrolyze considerable quantities of milk sugar before converting it into lactic acid.

Origin of oxydases and reductases in cow's milk, O. JENSEN (*Rev. Gén. Lait.*, 6 (1906), Nos. 2, pp. 34-40; 3, pp. 56-62; 4, pp. 85-90).—The conclusions drawn by the author from his studies are as follows:

The peroxydase in cow's milk is derived solely from the animal and probably in great part from the food.

The catalase is derived to a small extent from the leucocytes (the catalase of fresh milk) and to a large extent from bacteria.

The hydrogenase and the reductase are wholly of bacterial origin.

The aldehyde catalase (the reductase of fresh milk) is derived entirely from the milk globules.

The oxidation index of milk, E. COMANDUCCI (*Gaz. Chim. Ital.*, 36 (1906), II, No. 5-6, pp. 813-815).—The number of cubic centimeters of tenth-normal potassium permanganate required in the presence of sulphuric acid to oxidize 1 cc. of milk was found to vary with the different kinds of milk. Cow's milk gave figures varying from 50 to 52, goat's milk from 44 to 46, and sheep's milk from 43 to 48.

Investigations on Storch's reaction, M. SIEGFELD and G. SAMSON (*Molk. Ztg.*, 21 (1907), No. 5, pp. 103, 104, *dgm.* 1).—Milk which had been heated at 80 to 100° C. showed no coloration upon the addition of 2 drops of hydrogen peroxid and 2 drops of a 2 per cent solution of paraphenyldiamin. When, however, 2 drops of formalin (1:1) had been added to 100 cc. of the milk before heating, the reaction was similar to that for raw milk. This difference was marked for 10 days. Objections which have recently been raised to the value of Storch's reaction are consequently considered groundless. The reaction was less marked when larger quantities of formalin had been added to the milk, and the strongest reaction was obtained when 5 drops of a 1:10 per cent solution had been used. It was immaterial whether this addition was made before or after heating. Other experiments with different amounts of formalin and varying quantities of the reagents are also reported.

Sterilization of milk with hydrogen peroxid, E. ROUSSEAU (*Indus. Lait. [Paris]*, 32 (1907), Nos. 3, pp. 41-43; 6, pp. 89-91).—A review of the literature leads the author to conclude that Budde's method of sterilizing milk with hydrogen peroxid does not in general give the positive and certain results secured by pasteurization.

Note on the occurrence of diphtheria bacilli in milk, W. E. MARSHALL (*Jour. Hyg. [Cambridge]*, 7 (1907), No. 1, pp. 32-34).—The author notes the isolation from milk of the diphtheria bacillus in a virulent form.

Preliminary report on the water content, melting point, and keeping quality of butter, J. MICHELS and F. S. SILVER (*South Carolina Sta. Bul.* 125, pp. 14).—The authors undertook to investigate the influence of the water content of butter upon its keeping quality, but were unable to secure samples with markedly different amounts of moisture by the method given in Bulletin 76 of the Iowa Station (E. S. R., 15, p. 1114). The work as carried out was therefore restricted to a study of some of the factors which have been considered as affecting the water content of butter, some attention, however, being given to the melting point and keeping quality. The results obtained are summarized as follows:

"Butter churned moderately soft and then overchurned in the wash water to particles the size of hens' eggs averaged only a trifle higher in water content than normally churned butter.

"The melting point of butter fat appears to have no influence on the water content of butter.

"The water content of butter made from very rich cream and medium rich cream is the same.

"Brine salting increases the water content of butter about 1 per cent over dry salting.

"The average of fifteen trials shows that butter worked two minutes contains 0.61 per cent more water than butter worked four minutes.

"Normal cream overchurned in half churnful of wash water to particles the size of hens' eggs increased the water content of the butter only slightly.

"The melting point of butter fat from three different feeds varied as follows: (1) When 10 lbs. of wheat bran were fed with 45 lbs. of corn silage, the melting point was 92.9° F. (2) When 6 lbs. of cotton-seed meal were fed with 45 lbs. of corn silage, the melting point was 98.6° F. (3) When 6 lbs. of linseed meal were fed with 45 lbs. of corn silage, the melting point was 91.5° F.

"Butter worked two minutes possesses poorer keeping quality than similar butter worked four minutes.

"Butter worked only two minutes presents a leaky appearance.

"Butter churned soft and then overchurned in wash water to particles the size of hens' eggs possesses a comparatively weak body.

"Churning butter soft is conducive to a heavy loss of fat in the buttermilk.

"Butter from 5 lbs. of cotton-seed meal fed in conjunction with corn silage possesses an excellent grain and body."

Water in butter, J. WAUTERS (*But. Soc. Chim. Belg.*, 20 (1906), No. 11-12, pp. 365-373).—The author considers an excess of water an adulteration, the same as the addition of foreign fats, and points out that the regulations in force in Belgium are insufficient to prevent this fraud. In determining the water content of butter kept for some time, the sample, according to the author, should be obtained from the central portion, as the exterior has lost much by evaporation.

The presence of an abnormal amount of water in butter, A. TRILLAT (*Indus. Lait. [Paris]*, 32 (1907), No. 10, pp. 205, 206).—The author comments upon the frequent occurrence of an abnormal amount of water in butter and discusses briefly methods of determination and prevention.

On the origin of aldehydes in cheese, TRILLAT and SAUTON (*Compt. Rend. Acad. Sci. [Paris]*, 144 (1907), No. 9, pp. 495-498).—The presence of acetic aldehyde in cheese is attributed to the fermentation of lactose by yeasts. The amount of aldehyde produced is considered dependent upon a number of conditions, including the kind of yeast, exposure to light, alkalinity of the medium, the amount of lactose present, and the aeration of the cheese. Conditions favoring the formation of aldehydes and hence a bitter taste in the cheese are considered to be the preparation of the curd at too low a temperature and draining for too long a period.

Influence of temperature on the manufacture, ripening, and preservation of soft cheese, MAZÉ (*Indus. Lait. [Paris]*, 32 (1907), No. 9, pp. 161-169).—The importance of controlling temperature in the different stages of cheese making is discussed. The advantages of introducing mechanical refrigeration are emphasized.

The salting of soft cheese, M. MESNIL (*Indus. Lait. [Paris]*, 32 (1907), No. 9, pp. 187-189).—The author discusses the rôle played by salt in the manufacture of soft cheese and the manner in which the salting should be done.

The literature of milk and dairying, 1906, R. W. RAUDNITZ (*Separate from Monatsschr. Kinderheilk.*, 5 (1906), No. 6, pp. 55).—This is a review of the literature of milk during 1906.

On some chemical properties of casein and their possible relation to the chemical behavior or other protein bodies, with special reference to hydrolysis of casein by trypsin, T. B. ROBERTSON (*Jour. Biol. Chem.*, 2 (1907),

No. 4, pp. 317-383).—In the extended investigations here reported casein was used as a means of studying the relation between the ion proteids and the molecular compounds of protein bodies with electrolytes and also the influence of electrolytes upon tryptic digestion. A method for the quantitative estimation of casein is included in the article.

The industrial utilization of casein, D. SIDERSKY (*Indus. Lait. [Paris]*, 32 (1907), *No. 11, pp. 231-238*).—This is a general report on this subject, including the preparation of casein and the various uses made of it.

Wine and its chemistry, P. ARAUNER (*Der Wein und seine Chemie. Kitzingen: A. Wirth, 1906, pp. IX+189, figs. 38*).—This is a practical handbook on the manufacture, examination, and valuation of wines.

Sulphuring and refrigeration in wine making, F. COUSTON and E. DELORME (*Prog. Agr. et Vit. (Ed. l'Est)*, 28 (1907), *Nos. 8, pp. 237-245; 9, pp. 267-273*).—Wine-making experiments in Tunis are reported. The best results were obtained by the use of about 40 gm. of sulphurous acid per hectoliter of must. This retarded fermentation for 3 to 5 days, or until the free sulphurous acid was reduced to less than 5 gm. per hectoliter. Equally good results were obtained with sulphur fumes, potassium metabisulphite, and sodium bisulphite. The cost is considered the most important consideration as to which form of sulphur to use. The relative cost of 40 gm. of sulphurous acid when sulphur, sodium bisulphite, and potassium metabisulphite were used was proportionately 1:13:24.

The new methods of making dry wines, C. MAYER (*Agr. Jour. Cape Good Hope*, 30 (1907), *No. 1, pp. 70-75*).—The methods employed by the author are outlined and fermentation records are reported.

Austrian wines, B. HAAS (*Ztschr. Landw. Versuchw. Österr.*, 10 (1907), *No. 1, pp. 1-26*).—Analyses of 177 samples of wine from various parts of Austria are reported.

Progress in the manufacture of beet sugar in 1906, E. O. VON LIPPMANN (*Chem. Ztg.*, 31 (1907), *No. 11, pp. 123-125*).—This is a general review of the literature of the beet-sugar industry during 1906 from the standpoint of agriculture, technology, and analytical chemistry.

VETERINARY MEDICINE.

Diseases common to man and animals, E. MOSNY ET AL. (*Maladies Communes à l'Homme et aux Animaux. Paris: J. B. Baillière & Sons, 1906, vol. 4, pp. 428, figs. 26*).—In this volume attention is given to a discussion of tuberculosis, scrofula, glanders, actinomycosis, anthrax, psittacosis, rabies, tetanus, pork measles, trichinosis, and ankylostomiasis. In the account of each disease a discussion is given of the etiology, symptoms, development, conditions of intertransmission, and treatment.

Album guide to sanitary inspection of meats, E. AUREGGIO (*Album Guide de l'Inspection Sanitaire des Viandes. Lyon: Soc. Lyonnaise Photochromographie, 1906, pp. 6, pls. 90*).—The purpose of this volume is to present illustrations of normal and pathological conditions which are of interest in the inspection of the meat of all kinds of animals used for food. The illustrations are for the most part colored and the text is confined to legends describing the various figures.

Annual report on progress in the study of pathogenic micro-organisms, P. VON BAUMGARTEN and F. TANGI (*Jahresber. Path. Mikroorgan.*, 20 (1904), *pp. XII+1106*).—The present article contains a classified review of literature on the subject of pathogenic micro-organisms published in 1904. This review

has been made along lines very similar to those followed in previous reports, but particular attention has been given to pathogenic protozoa. A general author and subject index is appended to the volume in addition to departmental indexes throughout the text.

The process of suppuration in domestic animals, M. KREITZER (*Wchuschr. Tierheilk. u. Viehzucht*, 50 (1906), No. 17, pp. 921-928).—As a result of a study of various cases suppuration in different domestic animals the author comes to the conclusion that in the horse the majority of cases of suppuration is due to *Staphylococcus pyogenes aureus et albus*, while in cattle and sheep *S. pyogenes* is most active, and in hog and dog, *S. pyogenes aureus*.

Report of the State veterinarian, L. PEARSON (*Ann. Rpt. Penn. Dept. Agr.*, 11 (1905), pp. 103-128).—During the year under report considerable attention was given to outbreaks of rabies and glanders and to the repression of anthrax and tuberculosis. The campaign of the State veterinarian against tuberculosis has been well organized upon a satisfactory basis and is yielding visible results. The author is confident that with the continuation of his plan upon a conservative basis tuberculosis will become so reduced in extent as to be of little economic importance in public health. Copies are given of various State laws relating to animal diseases, and brief notes are presented on the prevalence of actinomycosis, contagious abortion, and other diseases.

Report of the chief inspector of stock, R. E. WEIR (*Jour. Dept. Agr. West Aust.*, 14 (1906), No. 5, pp. 342-346).—Pleuro-pneumonia occurred in only one outbreak during the year and that was promptly eradicated. Tuberculosis is reported as unusually common among pigs. Brief notes are also given on ticks and the general state of health of cattle in the colony.

Relationship between bovine and human tuberculosis, ZWICK (*Ztschr. Fleisch u. Milchhyg.*, 17 (1906), No. 3, pp. 69-81).—In this article the author reports the results of his investigation of certain cases of artificial transmission of pure cultures of human and bovine tubercle bacilli upon cattle, the distinction between bovine and human types of tubercle bacilli, and of a supposed case of the transmission of tuberculosis to two children in one family through the agency of milk.

The author found that the bovine tubercle bacilli were far more virulent for cattle than human bacilli, and that injection into the udder through the milk ducts is a very satisfactory method of testing the virulence of tubercle bacilli. The opinion is given that the establishment of two distinct types of tubercle bacilli is fully justified. The evidence for the transmission of tuberculosis to children through milk was not conclusive in the particular cases examined, but the author believes that such transmission may occur, and recommends that the authorities concerned should in all cases require a strict sanitary control, particularly of milk supposed to be of high quality and used in feeding children.

The demonstration of tubercle bacilli in market milk, G. KUHN (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 2 (1906), No. 1, pp. 58-61).—According to the experiments of the author the addition to milk of 0.5 per cent boric acid either as a powder or in solution is sufficient to prevent the coagulation of the milk for a period of 15 days. This addition of boric acid does not exercise any apparent effect upon tubercle bacilli which may be present in milk.

Work of the commission on tuberculosis in animals, H. MITCHELL (*Ann. Rpt. N. J. Bd. Agr.*, 33 (1905), pp. 209-216).—During the inspection of cattle 487 were found to be tuberculous and were slaughtered, the owners being paid an average indemnity of \$21.59 per head. The more progressive dairymen are all desirous of having herds tested in order to get rid of tuberculosis.

The infectiousness of different cultures of tubercle bacilli, K. VAGEDES and C. FRAENKEL (*Ztschr. Hyg. u. Infektionskrank.*, 55 (1906), No. 2, pp. 321-330).—The authors present opposing sides of the controversy regarding certain methods of determining the virulence of tubercle bacilli of different origin. One of the chief points of controversy involves the question whether rabbits or guinea pigs are the more suitable experimental animals for determining the degree of virulence of tubercle bacilli.

The virulence of different cultures of tubercle bacillus, C. FRAENKEL and E. BAUMANN (*Ztschr. Hyg. u. Infektionskrank.*, 54 (1906), No. 2, pp. 247-261).—During the investigations reported in this paper, 37 cultures of tubercle bacilli were tested from different cases of human tuberculosis. The experimental animals included rabbits, rats, mice, and guinea pigs, but the authors state that the guinea pig is the only one of these animals which is well adapted for demonstrating slight differences in the virulence of different cultures of tubercle bacilli. As a matter of fact, little difference was observed in the virulence of the various cultures which were used. In some cases cultures which had been maintained for a long time on artificial nutrient media showed no diminution of their virulence.

Immunization with anthrax and tubercle bacilli attenuated by sunlight, A. DI DONNA (*Centbl. Bakt. [etc.], I. Abt., Orig.*, 42 (1906), Nos. 7, pp. 642-646; 8, pp. 771-775).—In the investigations reported in this article it was found that sunlight has a pronounced effect in reducing the toxic effect of the tubercle bacillus. Naturally the effect of sunlight becomes more pronounced as the exposure of the tubercle bacilli to it is lengthened. Attention is called to the fact that abscesses, general intoxication, and death may follow upon inoculation with tubercle bacilli killed by heat or by any other means except sunlight. It appears from the author's experiments, however, that sunlight has the effect of attenuating or entirely destroying the most active toxic bodies contained in the tubercle bacillus.

The cause of trembles in cattle, sheep, and horses and of milk sickness in people, E. L. MOSELEY (*Ohio Nat.*, 6 (1906), Nos. 4, pp. 463-470; 5, pp. 477-483).—A historical statement is given of the prevalence of trembles and milk sickness, particularly in the Central States. Since 1840 suspicion has been fixed on white snake root (*Eupatorium aceratoides*) as the cause of the trouble, and certain experiments carried out previously to those of the author seemed to give color to this belief.

Portions of the plant and extracts from the same were fed to cats, dogs, rabbits, sheep, and other animals and produced poisonous effects. The symptoms produced in the experimental animals included general nervousness, weakness, and trembling, and the results were often fatal when large quantities were fed. During the experiments a boy accidentally received some of the plant and was affected with similar symptoms. The meat of a sheep poisoned with the plant produced toxic effects in the cats which ate it.

Post-mortem examinations failed to disclose any characteristic lesions or pathological conditions. The kidneys were somewhat enlarged, but other organs appeared to be in a normal state. The plant seems to produce its toxic effects rapidly, but is not irritant.

African coast fever, H. CREUTZ (*Berlin. Tierärztl. Wchuschr.*, 1906, No. 47, pp. 843, 844).—It has been established by experiment that African coast fever may be transmitted by means of *Rhipicephalus appendiculatus*, *R. simus*, *R. nitens*, *R. evertsi*, and *R. capensis*. Partly on this account G. Neumann has proposed that the five named species should be grouped together in a subgenus as distinct from other species commonly referred to this genus. The symp-

toms of African coast fever are described. The author recommends as a preventive for the disease that cattle be dipped in an arsenical solution.

The piroplasma observed in cattle in Japan, M. MIYAJIMA and G. SHIBAYAMA (*Ztschr. Hyg. u. Infektionskrankh.*, 54 (1906), No. 2, pp. 189-200, pl. 1).—The authors studied the morphology and biology of the piroplasma which occurs in the blood of cattle in Japan with particular reference to other pathogenic organisms of this class.

It appears that inoculation with the piroplasma will produce a mild disease resembling in some respects cases of Texas fever, but the form of the blood parasite usually observed in Texas fever is not present in the blood. The parasite in question is believed to be of a harmless nature under ordinary conditions.

Suggestions of the federal council with regard to an imperial law on foot-and-mouth diseases, KRUEGER (*Deut. Tierärztl. Wehnschr.*, 14 (1906), No. 49, pp. 617-626).—The German law regarding the suppression of animal diseases passed in 1880 and amended in 1894 is to be replaced by a new law. A large mass of material has been collected by the federal council through official veterinarians and others which will doubtless serve as a basis for the new imperial law. An abstract is given of the material thus collected, together with a preliminary draft of the proposed law.

Foot-and-mouth disease, C. STABILINI (*Clin. Vet. [Milan]*, 29 (1906), No. 48, pp. 1153-1155).—Attention is briefly called to the strict precautions which are necessary to prevent the spread of foot-and-mouth disease after an outbreak has occurred. Quite frequently the quarantine regulations are not maintained as strictly as they should be and in such cases disastrous results may follow.

A form of gangrene among cattle in Paraguay, ELMASSIAN and R. URIZAR (*Ann. Inst. Pasteur*, 20 (1906), No. 11, pp. 969-975, fig. 1).—A form of gangrene was observed as a quite common disease of cattle in Paraguay. The first and most striking symptom was the appearance of a gangrenous plaque 10 to 15 cm. in diameter on the perineum. Occasionally these patches occurred also on the ears, tail, and udder and caused the destruction and sloughing off of affected tissue. No success was had in attempts to transmit the disease in experimental animals either with the blood of affected animals or with diseased tissue.

Further notes on the treatment of milk fever by air infusions, RABUS (*Wehnschr. Tierheilk. u. Viehzucht*, 50 (1906), No. 44, pp. 861-863).—The author reports success from the air treatment in cases of milk fever even where great weakness has persisted for 2 to 5 days after the cerebral symptoms have disappeared.

The treatment of tympanites in cattle, J. VENNERHOLM (*Svensk Vet. Tidskr.*, 11 (1906), No. 11, pp. 476-478).—The treatment of tympanites should vary according to the symptoms presented in each individual case and according to the severity of the trouble and its cause.

Salt sick (Bovine uncinariasis), C. F. DAWSON (*Florida Sta. Bul.* 86, pp. 14).—Bovine uncinariasis is a chronic disease characterized by low fever, loss of appetite, a progressive emaciation, and anemia. It occurs throughout Florida and is also reported from Texas and Cape Cod. There are a number of species of *Uncinaria* which attack various domestic animals and man. In cattle the disease is most prevalent in range animals, the embryo worms being swallowed in contaminated food or water.

The disease may be diagnosed by the existence of pronounced anemia and by the detection of parasitic worms in the feces. The lesions are chiefly anemia and dropsy.

Bovine uncinariasis may be best controlled by attention to the hygiene of the

food and water. Rotation of pasture is therefore advocated, together with the administration of tonics and vermifuges, such as sulphate of iron, calomel, creolin, lysol, gasoline, and thymol.

Treatment and prevention of stomach worms and diarrhea of calves and lambs, J. LIGNIÈRES (*Bol. Min. Agr. [Buenos Ayres], 6 (1906), No. 1-2-3, pp. 110-120, figs. 4*).—In many instances it is difficult to determine without some study whether a particular outbreak of diarrhea in calves and lambs is due to bacterial infection or to the presence of stomach worms. In order that stock growers may save time in applying an efficient remedy, the author recommends the use of a mixture containing 1 to 2 parts of creosote, 4 parts of carbolic acid, 8 parts of naphthalene, 4 parts of kamila, and 16 parts of male fern. This mixture is effective against either stomach worms or intestinal bacteria and has given good results when administered in water as a drench. For young calves and sheep the usual dose is 5 cc. in a small quantity of water.

Some problems in sheep diseases, F. S. H. BALDREY (*Jour. Trop. Vet. Sci., 1 (1906), No. 4, pp. 387-409*).—As a rule little attention is given to sheep and goat diseases in India, but serious diseases are nevertheless present to considerable extent. A disease commonly known as gillar was studied by the author, with the result that a parasite belonging apparently to the genus *Bilharzia* was found and is considered the chief cause of the disease. The symptoms resemble those of liver rot, and include progressive anemia and great debility.

A tick disease which causes considerable mortality in sheep is apparently transmitted by a tick belonging to the genus *Ornithodoros*. The disease is of a chronic nature, and the symptoms include loss of wool, a cough, discharge at the nose, and general debility. The actual cause of the disease is at present uncertain.

Another disease of sheep and goats in India is known as juvee, and is characterized by diarrhea and excessive anemia. It is apparently a coccidiosis. The best method of prevention consists in the isolation of diseased animals and the avoidance where possible of wet pastures. The author has also made observations on a disease locally known as "wah," which somewhat resembles rinderpest.

Sheep pox in the district of Kulm, HAAKE (*Berlin. Tierärztl. Wehnschr., 1906, No. 48, pp. 855-857*).—The author describes the circumstances surrounding outbreaks of sheep pox, and comes to the conclusion that the spread of this and other highly infectious diseases is not sufficiently well controlled by mere announcement of the existence of the case in the usual columns of legal matter. It is suggested that the existence of such diseases should be at once announced in two or three newspapers of the widest circulation, in order that the matter might be promptly brought to the attention of all concerned.

Infectious cerebro-spinal meningitis, H. J. VAN DER SCHROEFF (*Tijdschr. Veeartsenijk., 34 (1907), No. 4, pp. 242-244*).—The symptoms of this disease are briefly described, with particular attention to the differences in symptoms depending on whether the nervous form of the disease is developed or not.

Tetanus following enteritis, H. HOLTERBACH (*Berlin. Tierärztl. Wehnschr., 1906, No. 47, pp. 844-846*).—The conditions under which the tetanus bacillus gains entrance to warm-blooded animals are briefly discussed. A detailed statement is presented of the symptoms observed in a case of tetanus, in which infection apparently took place through the wall of the small intestines rendered particularly susceptible by a case of enteritis.

Pernicious anemia in horses, J. BEGHIN (*Ann. Méd. Vét., 55 (1906), No. 12, pp. 692-694*).—A brief description is given of an enzootic outbreak of this disease with notes on the symptoms and the appearance of the blood. It was impossible to demonstrate either bacteria or other parasites in any of the cases

examined. The treatment consisted in isolation of the sick animals and a thorough disinfection of the premises.

A disease simulating dourine caused by filaria, H. T. PEASE (*Jour. Trop. Vet. Sci.*, 1 (1906), No. 3, pp. 414-416).—Notes are given on a few cases which have been observed among horses in which irregular plaques appeared on various parts of the skin together with other symptoms which closely resemble those of dourine. A careful study, however, showed that the cases were not dourine and that the animals did not readily spread contagion. An examination of the affected patches showed the presence of a filaria.

The interaction of Trypanosoma equiperdum and T. evansi, A. LINGARD (*Jour. Trop. Vet. Sci.*, 1 (1906), No. 3, pp. 353-386, pls. 3).—In the course of his study of trypanosome diseases the author found that mares which had successfully passed through an attack of dourine and resisted a second inoculation of the same disease do not thereby acquire any immunity to *T. evansi*. Similarly, ponies and donkeys, after recovering from dourine, succumb readily to surra. It appears, however, from experiments with donkeys that immunity acquired during pregnancy may be transmitted to the offspring.

Vaccination against swine plague and hog colera, O. PROFÉ (*Fortschr. Vet. Hyg.*, 1 (1906), No. 8, pp. 169-176).—A brief account is given of several of the sera which have been proposed for use in the treatment of this disease. In one instance where Klett's serum was used a cure was brought about in hogs which had just begun to show symptoms of swine plague and the disease was prevented from developing in exposed hogs. Of three hogs which were badly affected at the time of vaccination one recovered while the other two succumbed.

The pectoral form of swine plague, ENDERS (*Berlin. Tierärztl. Wchnschr.*, 1906, No. 49, pp. 867-870).—On the basis of an extended study of different forms of swine plague the author comes to the conclusion that the catarrhal form of pulmonary inflammation in swine plague is the most frequent. It was also ascertained that there are cases of pleuritis of a specific and infectious nature due to swine plague, but without any evidence of pneumonia, and on the other hand there are cases of pneumonia due to swine plague which are of a catarrhal nature and in which the pleura is not affected. In some instances, the author observed swine plague in the form of an exclusive inflammation of the pleura without any involvement of the lungs.

The transmission of swine erysipelas, SCHMUCK (*Berlin. Tierärztl. Wchnschr.*, 1906, No. 47, p. 847).—The author relates the circumstances of the infection of one of his hands while examining the heart of a hog dead of the disease. The infection spread downward along the thumb and upward to the wrist, after which the disease healed spontaneously.

The fluid of echinococci and cysticerci, E. JOEST (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 2 (1906), No. 1, pp. 10-28).—The bladder fluid of echinococci and *Cysticercus tenuicollis* when inoculated intravenously or into the body cavity produced no effect on experimental animals and therefore may be considered as containing no poisonous principle. It was further demonstrated that the blood serum of animals affected with echinococci and cysticerci exercises no precipitating effect upon the fluid of these parasites.

The occurrence of trichinæ in rats, L. BAHR (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 2 (1906), No. 1, pp. 62-65).—Statistics are given on the occurrence of trichinæ in rats with especial reference to the connection between the parasitism of these animals and pigs. The author believes that in many instances the infestation of pigs with trichinæ can not be accounted for by supposing that they ate infested rats. This assumption becomes improbable when it is considered that high-grade hogs are commonly raised under conditions where they seldom have opportunity to eat rats. The author believes that

some of the infestation with trichinae must be explained as occurring through the feces of infected hogs.

A study of rabies, STÜRTZBECHER (*Ztschr. Veterinärk.*, 18 (1906), No. 11, pp. 478-484).—Notes are given on various methods of diagnosing rabies with particular reference to the importance of Negri's corpuscles. One of the most important practical points in the control of rabies is a certain means of reliable diagnosis. This, the author believes, is found in Negri's corpuscles.

Vaccination against rabies by the Pasteur method, R. NITSCH (*Centbl. Bakt. [etc.]*, I. Abt., Orig., 42 (1906), Nos. 7, pp. 647-658; 8, pp. 775-783).—The application of Pasteur's method in the control of rabies has been found to reduce decidedly the percentage of mortality from rabies in animals and man. The incubation period of the disease, however, appears not to be extended by the Pasteur treatment.

Dog distemper and the filterable organism of Carré, J. LIGNIÈRES (*Bull. Soc. Cent. Méd. Vét.*, 83 (1906), No. 2, pp. 622-630).—As a result of his study of this disease, the author comes to the conclusion that there is a specific filterable organism in the body fluids of dogs affected with distemper, and that this organism is the principal cause of the distemper. There may be, however, other organisms, particularly *Pasteurella canis*, which, acting in connection with the specific organism of distemper, may cause complications or peculiar symptoms in the course of the disease.

Preliminary note on the development of Piroplasma canis in the tick, S. R. CHRISTOPHERS (*Brit. Med. Jour.*, 1907, No. 2402, pp. 76-78, figs. 26).—Much difficulty has been experienced in following the life history of blood parasites in ticks. The author had opportunity to study this matter by reason of the unusual prevalence of canine piroplasmiasis in India. The tick chiefly concerned in transmitting the disease was *Rhipicephalus sanguineus*. The various developmental stages are described and illustrated by the author, and it is suggested that the life history, as observed in *Piroplasma canis*, may be very similar to that of other related parasites.

Further studies on fowl plague, R. OSTERTAG and R. BUGGE (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 2 (1906), No. 1, pp. 1-9, fig. 1).—It was determined by inoculation experiments that fowl plague may be transmitted to geese, and that in these birds the disease assumes a peculiar form showing pronounced cerebral symptoms, while the blood is not always infectious. It was found that the virus of fowl plague could be kept in the laboratory for at least 100 days without losing its virulence even when the material was subjected to light. The resistance of the virus to ordinary disinfectants is of average degree.

No success was had in cultivating the virus in collodion sacs inside the body cavity of fowls. It appears that fowls which have once recovered from the disease possess in their blood protective substances which, however, are of little strength.

The use of the pigeon for testing immune fowl cholera serum, A. BRAUN (*Fortschr. Vet. Hyg.*, 4 (1906), Nos. 8, pp. 174-183; 9, pp. 198-211).—The pigeon has been extensively used as an experimental animal in the laboratory for testing the virulence of fowl cholera virus and the effectiveness of sera developed in studying this disease. The author made a careful study of the problem with the special object in view of determining the suitability of the pigeon in this work. The conclusion is reached that the pigeon is not suitable for testing fowl cholera serum chiefly for the reason that this bird appears to have a pronounced specific reaction to fowl cholera. The mouse, on the other hand, is well adapted for the purpose.

RURAL ENGINEERING.

Studies on the irrigation of Jauja, D. BALDIZAN (*Bol. Min. Fomento [Peru], Dir. Obras Pub., 2 (1906), No. 1, pp. 67, figs. 11, dgn. 1*).—These studies have been carried on in the valley of Jauja, which is traversed by the Mantaro River, but lacks the necessary precipitation to render the soil productive.

To supply 3,800 hectares of these lands with water and to provide water for the municipal and household purposes of the city of Jauja, with a probable population of 10,000 people, a canal is proposed which will divert 4,000 liters per second from the Mantaro River and carry it to the vicinity of Jauja. The length of the canal will be 21.9 kilometers, and it will have a grade varying from 1 meter in 1,000 in tunnels and rock cuts to 2 per 1,000 in the aqueducts and from 0.8 to 0.3 per 1,000 in the earth sections. Cross sections of the canal in various kinds of material are shown, Bazin's formula having been used in the determination of the area of cross section.

The distribution of water by measurement [R. G. KENNEDY], (*Proc. Irrig. Conference, Simla, 1904, 1, pp. 137-139*).—The disadvantages of the usual distribution of water according to area are cited and the proposed distribution by measure with its advantages and difficulties is discussed. The system of distribution and assessment by volume where the user is charged according to the number of acre-feet actually used is considered inapplicable in India, except in those cases where the water is distributed over a comparatively small and compact area situated in close proximity to the source of supply.

The "module system" is described as a system in which the cultivator pays a fixed rate for the volume of water allowed to pass through a sluice at prescribed intervals of time in sufficient quantity to mature the crop, the discharge of the sluice bearing a certain proportion to the area to be irrigated. By this system the charges during rainy seasons would be the same as during dry seasons. The module system is undeveloped, owing to the difficulties in devising modules, arranging a scale of charges, and overcoming the prejudices of irrigators.

Contributions from the agricultural experiment station of the University of Göttingen, VON SEELHORST (*Jour. Landw., 54 (1906), No. 4, pp. 313-342, pls. 2*).—From the experiments conducted on the relation between water evaporation and drainage in fallow soils, a table has been constructed from which the following conclusions are derived:

"In general, sandy soils give a greater quantity of drainage water for the same precipitation than do loam soils. Only in June and July of 1905 and in February of 1906 was the reverse true.

"Evaporation is always greater from a loam than from a sandy soil, which is due usually to the greater impermeability of the former to rain and its greater capillarity, which brings the water to the surface more readily in dry weather."

Further experiments have been carried on in the use of water upon rye, barley, wheat, and potatoes, the crops being grown in tanks and the amount of water actually used by the plant being computed from the amount of water received by rainfall after deductions are made for evaporation and drainage. Four tanks were employed with the loam soils, in three of which wheat, rye, and potatoes were grown with the remaining tank left fallow. The weights of the tanks were taken at frequent intervals. In computing the amount used by the plants it was found necessary to estimate the amount evaporated by the soil, since it was assumed that the evaporation from the fallow soil surface would not be the same as from the soil surface shaded by plants.

The results of the experiments indicate that on a loam soil wheat requires

333 gm. and rye 375 gm. of water per gm. of dry substance of grain, and that potatoes require 277.7 gm. of water per gm. of dry substance of the tubers, or 66.3 gm. of water per gm. of fresh tubers. On loam soil the water requirement of rye is greater in April and May than that of wheat, but from the end of May to the time of harvesting of wheat its water requirement is greater than that of rye. From the end of May to the 21st of June the water requirement of rye increases very rapidly; that of wheat less so. Both crops reach a maximum requirement on the 21st of June. The use of water by potatoes increases from the end of May to the 10th of July very rapidly and from this date to the first of August remains always uniform. It then decreases, first rapidly and then more slowly, until the time of harvesting.

For sandy soils experiments were conducted in the same manner as for loam soils. The results show that rye requires 482.2 gm. and barley 454 gm. of water per gm. of dry substance of grain, and that potatoes require 60 gm. of water per gm. of fresh tubers.

Plates are included giving a graphical representation of the daily use of water by the plants in each experiment.

Rural and urban hydraulics, G. BECHMANN (*Hydraulique Agricole et Urbaine. Paris: Librairie Polytechnique, 1905, pp. 634, figs. 373*).—The author has compiled a general text on the subject.

The first part of the book is devoted to a treatment of the means of securing, storing, conveying, and lifting water, while the second part takes up the relation of water to agriculture. In the latter connection the physiological rôle played by water in the growth of plants is considered in some detail, following which is the chapter devoted to the use of water in irrigation with particular reference to the methods of applying water and the conditions governing its distribution, division, and sale. The various units of measurement used in France are explained and their equivalents given.

The fertilization and improvement of land by the deposition of silt is considered, and particular attention is given to the reclamation of marshes in relation to the natural conditions and special legislation governing the construction of such works. Some examples of marsh reclamation in Belgium and elsewhere are described. The subject of drainage occupies a long chapter, the theory and methods of construction of drains being given, together with an abstract of the special legislation on the subject.

In part 3, city water supplies and sewage are considered, the various structures necessary being illustrated and described.

Good roads bulletin, H. E. BLAKESLEE (*Jackson, Miss.: Dept. Agr. and Com., 1906, pp. 23*).—A bulletin published with the "objects of furnishing accurate information as to what each county of Mississippi is doing to improve the public roads, and to create a sentiment of rivalry that will assist in a betterment of road conditions in general."

The number of miles of public roads in each county, the extent, methods, and cost of improvements, and local opinions of the value of different methods are given in tabular form, the bulletin being concluded by some information on the use of road drags, methods of road construction, and cost data.

The use of alcohol and gasoline in farm engines, C. E. LUCKE and S. M. WOODWARD (*U. S. Dept. Agr., Farmers' Bul. 277, pp. 40, figs. 12*).—In response to a widespread demand for information on the adaptability of alcohol as a fuel for use in internal-combustion engines used in farming operations, this Office carried on a series of experiments with a twofold object: (1) To determine what can be done with alcohol in existing engines and (2) to learn what changes in the mechanism of the engine are necessary to secure the highest efficiency in the use of alcohol as a fuel. The present bulletin is a popular discussion of

these experiments and of the mechanism and operation of gas engines in general with a short treatment of the comparative cost and relative adaptability of different fuels. The principal conclusions derived from the experiments are as follows:

"Any engine on the American market to-day, operating with gasoline or kerosene, can operate with alcohol fuel without any structural change whatever with proper manipulation.

"Alcohol contains approximately 0.6 of the heating value of gasoline, by weight, and in the Department's experiments a small engine required 1.8 times as much alcohol as gasoline per horsepower hour. This corresponds very closely with the relative heating value of the fuels, indicating principally the same thermal efficiency with the two when vaporization is complete. . . .

"The thermal efficiency of these engines can be improved when they are to be operated by alcohol, first, by altering the construction of the carbureter to accomplish complete vaporization and, second, by increasing the compression very materially. . . .

"The exhaust from the alcohol engine is less likely to be offensive than the exhaust from a gasoline or kerosene engine, although there will be some odor, due to lubricating oil and imperfect combustion, if the engine is not skillfully operated.

"It requires no more skill to operate an alcohol engine than one intended for gasoline or kerosene.

"There seems to be no tendency for the interior of an alcohol engine to become sooty, as is the case with gasoline and kerosene. . . .

"In most localities it is unlikely that alcohol power will be cheaper or as cheap as gasoline power for some time to come."

Windmill electric plant requirements (*Engin. Rec.*, 55 (1907), No. 2, p. 47).—The essentials in installing a windmill electric plant have been stated by W. O. Horsnail, of England, as follows:

First, to ascertain the average daily load in ampere-hours during periods of maximum current consumption; second, to provide a storage battery of a capacity at least double this output; third, to install a dynamo of sufficient capacity to charge this battery in 12 hours; fourth, to design a dynamo to deliver an approximately constant voltage throughout a wide range of variation of speed; fifth, to erect a windmill of ample size to run the dynamo at full load with a 10-mile-an-hour wind; and sixth, to fit the windmill dynamo and all gearing connections with roller-bearings or other friction-reducing means. A large number of plants built to these specifications are said to be in successful operation in England.

The production and utilization of low temperatures, L. MARCHIS (*Production et Utilisation du Froid*, Paris: H. Dunod and E. Pinat, 1906, pp. IV+586, figs. 402).—This work is intended to supply a want long felt in France for a general text on the subject of refrigeration.

The introduction takes up the subject of the development of the refrigerating industry showing the manifold uses to which ice is at present put and giving statistics on the extent to which refrigeration is carried on not only in the packing and allied industries but also in transportation by land and water in the various countries. Following this several chapters are devoted to the thermo-dynamic theory of refrigeration and to descriptions of the principles underlying the action of different machines and their design, particular attention being given to the machines of the compression type. Different forms of condensers and evaporators are described and illustrated and the circulating medium discussed.

Some special applications of the use of refrigeration in dairies and breweries

are considered, following which are given some theoretical and practical instructions on the construction of cold storage warehouses, etc., and the schemes of piping and ventilation employed. Refrigerating cars as used in various countries are described and the equipment necessary on shipboard is discussed in considerable detail. Factories for the commercial manufacture of ice are fully described, and the special equipment necessary in the refrigeration and conservation of meats, vegetables, fruit, fish, eggs, etc., is dealt with in a comprehensive way. An extended chapter on the utilization of low temperatures in the manufacture and transportation of dairy products completes the book.

RURAL ECONOMICS.

[**Agriculture, immigration, and colonization in South Carolina**], E. J. WATSON (*Ann. Rpt. Comr. Agr., Com. and Immig. S. C., 3 (1906), pp. 75, figs. 12, chart 1*).—This is the third report by the State commissioner of agriculture, commerce, and immigration.

The commissioner points out the increased value of agricultural lands and discusses the agriculture of the State, the advantages of South Carolina to prospective agricultural settlers, the work of the department in the selection, importation, and care of immigrants from European countries, and the present status of the agricultural colonies now in operation in different sections of the State.

Agriculture in Italy, A. B. BUTMAN (*Daily Consular and Trade Rpts. [U. S.], 1907, No. 2812, pp. 1-3*).—In addition to notes on fruit and rice culture, poultry raising, and the production of other crops in Italy, this article discusses present labor conditions and presents statistics on the results of cooperation among farmers. At the close of 1905 the number of cooperative leagues was 982, with a membership of 221,913.

Agricultural Algeria in 1906, L. TRABUT and R. MARÈS (*L'Algerie Agricole en 1906. Algeria: Gort., 1906, pp. 531, pls. 5, figs. 77*).—This treatise describes quite fully the natural regions of Algeria, the soil, the water supply, cereal and forage crops and their methods of culture, viticulture, arboriculture, culture of tobacco, textiles and other industrial plants, ornamentals, vegetable culture, forests, animal production, agricultural education, agricultural credit and insurance, the steppes and Sahara. Detailed statistical matter is given in an appendix.

The agricultural credit banks were established in Algiers in 1901, and there were in March, 1905, 25 district mutual banks with 95 affiliated local banks for cooperative credit. The business transacted in 1904 was estimated at 2,893,171 francs.

Agricultural incomes in Switzerland, P. VAN BIERVLIET (*Rev. Gén. Agron., n. ser., 1 (1906), No. 12, pp. 542-544*).—This article reviews the results of a recent inquiry by the department of agriculture as to the incomes from small, moderate, and extensive farming in Switzerland.

For 1904 the average comparative net incomes were estimated as follows: Small farming, 2.55 per cent; moderate farming, operations of small, ordinary, and great importance, 2.63, 3.02, and 3.77 per cent, respectively; extensive farming, 3.52 per cent. The total income of farmers, including value of labor and interest on invested capital, averaged in 1904 3.49 francs per day. "These figures show that Swiss agriculture is not very remunerative," and it is attributed to the increased cost of labor and other elements entering into the cost of production.

Agricultural statistics of the Canton of Bern for 1904 and 1905 (*Mitt. Bern. Statist. Bur., 1906, No. 1, pp. 177*).—Statistics of acreage under cultiva-

tion and the yields and prices of cereals, vegetables, and fruits are reported. Notes are also given on the weather conditions in the different districts during the growing season and their bearing on crop production.

Investigations on the economic development and distribution of wealth in the Canton of Bern, C. MÜHELMANN (*Mill. Bern. Statist. Ber., 1905, No. 2, pp. VII+281*).—This is a general review of the history of the Canton of Bern, with more particular reference to its economic development.

Chapter 8 is devoted to a survey of agricultural development during the 19th century. The subjects treated include the production and sale of live stock; changes in systems of farm management and cultivation of land with especial reference to crop production; real estate and mortgages, agricultural credit and liens with a discussion of the causes and the consequences of indebtedness, and the advancement of agriculture by means of private, cooperative, and State aid. Statistics are presented to show the progress made during this period.

The farm help problem, A. H. SANDERS (*Breeder's Gaz., 51 (1907), No. 15, p. 531*).—The writer discusses the lack of competent farm help in the United States and other countries, points out some of the causes of this deficiency, and calls attention to the advantages offered to farm hands in this country. The greater dissemination of information on the latter point among agricultural laborers in foreign lands is regarded as likely to induce the emigration of competent help to the United States.

Farming on shares, D. ZOLLA (*Ann. Soc. Synd. Libre Agr. Périgord, 9 (1907), No. 2, pp. 20-28*).—The author defends the system of farming on shares as compared with payment in wages to agricultural laborers in France.

The author takes two typical illustrations of metayers with families in different provinces renting farms of which 26 and 33 hectares only were cultivated. The actual net returns from both farms and the shares to metayers and proprietors are given, and the financial results to the metayers compared with what could have been received in wages during 300 working days. The advantage of share farming over the wage system was estimated at 86 per cent. In addition to this financial gain the author enumerates other economic and social benefits arising only as a result of the metayer system which are enjoyed by the 344,000 metayers in France. At the same time the character of the proprietor and the efficiency of the farmer are regarded as important factors in securing the best returns under this system.

Report of the small holdings committee (*Jour. Bd. Agr. [London], 13 (1907), No. 10, pp. 597-604*).—This is an abstract of the report of the departmental committee appointed by the president of the Board of Agriculture and Fisheries, in April, 1905, to inquire into the administration and working of the Small Holdings Act of 1892.

After examining 58 witnesses and visiting a number of small holdings in Great Britain, the committee recommends among other things the direct control by a government department of the holdings with authority to make definite experiments, the amendment of the act for the greater protection and benefit of the small holder, the advancement of government loans to landowners at the lowest possible rate of interest to enable them to undertake the equipment of small holdings, the increase of State funds for agricultural instruction in rural districts, and promotion of all forms of agricultural cooperation by means of government loans on approved security of a central credit association.

The law authorizing loans to agricultural cooperative societies (*Bul. Statist. Lég. Compar., 31 (1907), No. 1, pp. 14-17; Bul. Mens. Off. Renseign. Agr. [Paris], 6 (1907), No. 2, pp. 133-135*).—The text of the law of December 29, 1906, amending the law of March 31, 1899, regulating the control of the 40,000,000 francs advanced by the French government to the regional banks

without interest. Through the district or regional banks loans are made to mutual credit banks and agricultural cooperative societies.

An agricultural cooperative society, D. L. DE CASTRO (*Rev. Agron. [Portugal]*, 4 (1906), No. 2, pp. 357-363).—This is a history of an agricultural cooperative society in Portugal since its origin in 1897. The author describes its development, the extent of its operations, and its objects. The latter conform largely to the aims of such organizations in Europe, namely, improvement of cultural methods, guaranties of pure seed, purchase of implements and machinery, formation of agricultural credit banks, mutual insurance, etc.

The development of agricultural cooperative societies in Germany, C. NEUMANN (*Fühling's Landw. Ztg.*, 55 (1906), No. 22, pp. 764-773).—Statistics are presented and discussed relating to the growth of rural associations in Germany. Data for 1905-6 regarding membership, value of property, amount of investments, profits, rates of interest, deposits, etc., are compared with preceding years. The associations are steadily growing in numbers and in influence, and are said to be an uplifting force in the economic life of the rural population.

Costs of hauling crops from farms to shipping points, F. ANDREWS (*U. S. Dept. Agr., Bur. Statis. Bul.*, 49, pp. 63).—The information contained in this bulletin was secured from correspondents in 1,894 counties in different States. The statistics deal particularly with 23 of the staple agricultural products grown in the United States and embrace the number of counties reporting, average miles to shipping, weight per load, cost per ton per mile, etc.

In a summary of these data the author says: "The average costs per 100 lbs. for hauling products from farms to shipping points vary in a number of instances roughly with the relative values of the articles hauled, the more valuable product being hauled often at greater cost than the less valuable product. Corn, wheat, oats, hay, and potatoes were hauled at costs ranging from 7 to 9 cts. per 100 lbs., cotton 16 cts., and wool 44 cts. per 100 lbs. Tobacco and hogs, however, cost only 10 cts. per 100 lbs. to be hauled from farms. The difference in cost of hauling between one product and another is largely due to the relative distance traversed and the relative size of load taken."

Statistics are also presented and discussed regarding the farmers' longest hauls and methods of hauling, with the effect of these factors on local and general prices. The quantity of farm produce hauled in 1905-6 is estimated at more than 49,000,000 tons and the cost of hauling at about \$84,684,000 for the most important crops mentioned. The value of better roads, quicker methods of loading and unloading, and other factors are also discussed in their bearing on the reduction in the cost of hauling.

Notes from correspondents regarding the conditions of wagon transportations in different parts of the United States are also appended.

The grain trade, the basis upon which it is conducted, and the methods used in the different countries of the world, A. DEUTSCHLÄNDER and W. KUNIS (*Der Handel mit Getreide, seine Einrichtungen und Grundlagen in allen massgebenden Ländern der Erde. Leipzig: M. Schäfer. 1906. pp. 439*).—This book contains detailed information on the extent of cereal culture and yield, exports and imports, consumption, methods employed in different grain markets, freight rates, etc. The numerous tables show the acreage and yields of wheat, rye, barley, oats, and corn; their consumption in the most important countries; the weekly average prices in the principal markets of the world in 1904 and 1905; the shipments, variation in quantity, and visible supplies of cereals each week from 1895 to March, 1906; the monthly shipments from 1895 to 1903; and other statistical data. The object is to present definite information useful to the grain trade.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 9 (1907), No. 3, pp. 17-24*).—In addition to the usual statistics and information on the condition of crops in the United States and foreign countries, this number has special articles on the cotton crop of the United States, 1790-1905, the monthly cotton crop situation, season of 1906-7, compared with preceding seasons; the wheat crop of various countries, 1902-1906; the flax crop of various countries, 1903-1905, etc.

AGRICULTURAL EDUCATION.

Report of the extension work of the [Rhode Island] College, A. E. STENE (*Bul. R. I. Col. Agr. and Mech. Arts, 2 (1906), No. 2, pl. 2, pp. 20, pl. 4*).—This is a report on the demonstration work for 1905-6, and includes articles on cooperative experiments in different parts of the State, extension lectures, special lectures, correspondence courses, popular bulletins, traveling libraries, the assistance of the grange, nature study, school gardens, and other miscellaneous work. In a "carpet-bag campaign," a representative of the college went from house to house and held neighborhood meetings (1) to give instruction in agricultural principles and suggestions of better methods, and (2) to ascertain just what are the principal difficulties, as well as the attitude of the farmer toward his vocation. There is also a report on the hydrocyanic-acid gas as a treatment for injurious insects, followed by suggestions for users of this remedy.

Report of the president, J. L. SNYDER (*[Mich.] Agr. Col. Bul. 1 (1906), No. 5, pp. 33*).—This report, in addition to the usual data concerning the work of the college during the fiscal year ended June 30, 1906, contains historical matter relating to the establishment of the college, the attendance during the past ten years, the preparation of students for admission, their sources of support and proposed occupation after leaving college, the development of experimental investigations, history of the experiment station, the history of farmers' institutes in the State, and an announcement of the semicentennial celebration to occur May 28-31, 1907.

It is shown that 78 per cent of those entering college during the year had attended high schools, that 27 per cent depend upon themselves for support while in college, and that 12 per cent intend to follow farming, forestry, or horticulture, while 52 per cent are uncertain as to their future occupation.

Report of the principal, 1906, H. B. FRISSELL (*Hampton Bul., 2 (1906), No. 2, pp. 30, figs. 6*).—The principal of the Hampton Normal and Agricultural Institute in his report for 1905-6 calls attention to the fact that of the 1,310 graduates of the school 85 per cent have taught at some time since leaving school. The three-year academic and industrial courses have been changed to four-year courses, and the courses in normal training, agriculture, trade, business methods, domestic science, and domestic art are continued.

Of the students enrolled in 1905-6, 39 per cent were from country schools, 50 per cent came from the country or small villages, and 34 per cent were from farms. The average acreage of these farms was 99 acres as against 57 acres in the preceding year. Sixty-eight per cent of the parents of these pupils owned their homes and an additional 10 per cent were buying homes, while 32 per cent of all the pupils came from houses of 7 rooms or more. These figures show an increase in the number of students from the country and an improvement in homes, as well as a larger ownership of land on the part of parents.

The report includes reports from the academic, agricultural, and home training departments, the trade school, military instruction and discipline, religious work, the library, museum, and other features of school work. The professor of agriculture reports that two new instructors have been added in the agricul-

tural department, and that a barn costing \$30,000 has been erected. He outlines the revised course in agriculture, and recommends the purchase of improved live stock for instructional purposes.

Agricultural education, H. O. SAMPSON (*Ann. Rpt. Penn. Dept. Agr., 11 (1905), pp. 621-623*).—An address in which the college courses in agriculture are outlined briefly, and some data concerning the progress in the development of secondary courses in agriculture are given.

Proceedings of the course for agricultural teachers (*Stockholm: Dept. Agr., 1906, pp. 366*).—This volume contains lectures and discussions given at the course for teachers of agriculture in Stockholm, Sweden, September 18-23, 1905. The topics of the lectures are The Importance of Green Manuring and How Practiced, by N. L. Forsberg; The Arrangement of Demonstration Plots and Their Application as Instructional Material, by N. H. Nilsson; Inoculation and Serum Therapy in Combating Diseases of Farm Animals, by J. Svensson; The Teachings of Recent Experiments and Experiences as to the Application of Artificial Fertilizers, by M. Weibull; The Arrangement of Practical Fertilizer Field Trials, by P. Bolin; The Importance of Keeping Accurate Accounts in the Dairy Industry, by G. Liljhagen; Recent Agricultural Machinery and Its Use on the Farm, by G. Timberg et al.; Some Problems in Animal Nutrition, by H. Winberg; Changes in Systems of Crop Rotation Made During Recent Years, by J. A. Sjöström; Crop Rotations, by N. L. Forsberg; Cooperative Purchasing and Sales Associations, by G. Leufven; Recent Progress in Butter Making, by N. Engström; Successful Butter Exports, by Fr. Bagge; Recent Investigations in Dairy Bacteriology, by Chr. Barthel; The Care and Application of Barnyard Manure, by H. G. Söderbaum; Recent Progress in the Manufacture of Cheese, by L. F. Rosengren; Proposed Changes in the Book-keeping of Control Test Associations, by Nils Hansson and H. Funkquist; Courses for Practical Farmers, by H. Juhlin-Dannefelt et al.; Award of Prizes for Small Farms, by Nils Hansson; and Traveling Stipends for Small Farmers.—F. W. WOLL.

The Macdonald movement, J. W. ROBERTSON (*Rpt. Women's Insts. Ontario, 1906, pp. 54-59*).—An address given at the annual convention of the Women's Institutes held at Macdonald College, December 13 and 14, 1905, in which the general features of the Macdonald movement are outlined, and a description is given of Macdonald College with its departments of farms, research, and instruction.

Outline of a course of study and reading on soil and its management, H. C. PRICE (*Ohio State Grange Ed. Bul. [1], pp. 7-12*).—This is a course of study prepared for members of the Ohio State Grange, and consists of 18 lessons based on Vol. I of Brooks's Agriculture.

Sanitation, MARY E. LEE (*Ohio State Grange Ed. Bul. [1], pp. 13-16*).—A course of 14 lessons based on Mrs. E. H. Richards Home Sanitation, and intended for members of the Ohio State Grange.

Qualifications necessary for teaching agriculture in common schools, C. A. McNABB (*Bien. Rpt. Okla. Bd. Agr., 2 (1905-6), pp. 279-285*).—An address before the Teachers' County Institute at Oklahoma City, in which the position is taken that while the teachers will not be expected to teach the practice of agriculture, they should be familiar with this side of the question and should also inform themselves on the work of the U. S. Department of Agriculture, the experiment stations, and the agricultural colleges. They should be up to date in their ideas of farm methods, improved implements, etc. To secure this training he recommends that they read farm journals and the publications of this Department and the experiment stations.

Agriculture in the common schools, W. M. GRASSOM (*School News and Pract. Ed.*, 20 (1907), No. 7, pp. 312, 313).—An argument for changes in the school curriculum which will relate the instruction to life problems either through instruction in elementary agriculture or through modification of arithmetic, geography, and other subjects, to make them apply more directly to rural conditions.

Country life education, W. M. HAYS (*U. S. Dept. Agr., Office Expt. Stas. Circ.* 73, pp. 13).—This is an address by W. M. Hays before the Pennsylvania State Board of Agriculture January 23, 1907, in which he discusses the new school movement springing out of the land-grant act of 1862 and subsequent acts of Congress for the aid of colleges of agriculture and mechanic arts, and the proposition to extend Government aid to agricultural high schools, mechanic arts instruction in city high schools, and home economics instruction in both country and city.

Annual report Winnebago County Schools, 1906, O. J. KERN (*Rockford, Ill.: Author, 1906, pp. 96, figs. 10½, map 1, dgm. 7*).—This report includes the following chapters: (1) The improvement of school grounds and buildings—a series of reports of things done and not done in the country-school districts of Winnebago County in the way of tree planting and otherwise improving the school grounds; (2) school gardens and elementary agriculture—sixty districts did school garden work in 1906 for the purpose of beautifying school grounds, making children acquainted with plant life, soils, conservation of moisture, protection from injurious insects, etc., and making the child a more efficient factor in the home garden work; (3) Winnebago County Farmer Boys' Experiment Club and Girls' Home Culture Club, including reports on various contests; (4) manual training in the country school; (5) books and pictures, with special reference to the 81 traveling libraries which circulate in rural districts of the county; (6) some statistics of the rural schools, and (7) the problem of consolidation of country schools.

Home science and the school curriculum, MARY C. MACPHERSON (*Rpt. Women's Insts. Ontario, 1906, pp. 102-106*).—An address before the annual convention of the Women's Institutes of Ontario, held at Macdonald College December 13 and 14, 1905, showing how home science may be taught in relation to other subjects in the school curriculum.

What form of industrial training is most practical and best suited to the country child? O. J. KERN (*El. School Teacher*, 7 (1907), No. 6, pp. 323-328).—The writer considers the educational value and practicability of teaching elementary agriculture, manual training, and home economics in the country schools.

The improvement of our rural schools and their surroundings, E. E. BALCOMB (*Bien. Rpt. Okla. Bd. Agr., 2 (1905-6), pp. 317-347, figs. 38*).—This paper is devoted to suggestions for the improvement of school buildings inside and out and the improvement of school grounds by means of planting trees, shrubbery, vines, and flowers. Many specific suggestions of means for bringing about these improvements are given, and the numerous illustrations aid in making these suggestions clear and forceful.

School grounds and school gardens, R. A. EMERSON (*Bul. Nebr. State Hort. Soc., Nos. 4, pp. 11, figs. 2; 5, pp. 11, figs. 3*).—Part 1 of this article is devoted to the planning of school grounds with reference to playgrounds, trees, shrubs, flowers, lawns, school gardens, and nurseries, and to suggestions and directions for planting and caring for trees and shrubbery.

Part 2 contains a discussion of school gardens which may or may not be located on the school grounds. How to prepare the ground, what, when, and

how to plant, and how to care for the school gardens are the principal topics discussed.

Gardening for schools, S. B. MCCREADY (*Ontario Agr. Col. and Expt. Farm Bul.* 152, pp. 32, figs. 4, maps 2).—This is one of the series of provincial teachers' bulletins, and treats of the place of gardening in education, cooperative experiments in agriculture, forestry, and horticulture, and children's home gardening organizations.

Gardening, W. J. GREEN (*Ohio State Grange Ed. Bul.* 2, pp. 12-16).—A course prepared for members of the Ohio State Grange, consisting of 18 lessons based on Green's Vegetable Gardening.

A course of study in farm crops, C. A. MCCALL (*Ohio State Grange Ed. Bul.* 2, pp. 6-11).—A course of study prepared for the members of the Ohio State Grange, consisting of 17 lessons based on Vol. II of Brooks's Agriculture.

Improvement of the corn crop, J. A. FOORD (*Agr. Col. Ext. Bul.* [*Ohio State Univ.*], 2 (1907), No. 7, pp. 16, figs. 14, dgm. 1).—Directions are given for selecting and making germination tests of seed corn.

Studies of corn and its uses, F. H. RANKIN (*Agr. Col. Ext. Univ. Ill.* [*Circ.*], 1906, Oct., 2, ed., pp. 40, figs. 5).—These include suggestions for studies by young people of the corn plant, studies of an ear of corn, preparing exhibits and using the score card for corn and for oats, studies of the different parts of a kernel of corn, commercial products of corn, and suggestions for 6 experiments with corn.

Report of the corn contest, E. C. BISHOP (*Ann. Rpt. Nebr. Bd. Agr.*, 1905, pp. 184-197).—This article gives particulars regarding the origin, progress, and final exhibition program and banquet of the Nebraska corn growing contest.

Tillage and cultivation, A. G. MCCALL (*Agr. Col. Ext. Bul.* [*Ohio State Univ.*], 1 (1906), No. 9, pp. 12, figs. 11).—A lesson in elementary agriculture, with suggestions for a number of experiments with soils.

Practical experiments with milk and butter, J. W. DECKER (*Agr. Col. Ext. Bul.* [*Ohio State Univ.*], 2 (1906), No. 4, pp. 9-13, figs. 8).—Ten experiments suitable for use in elementary schools are given. These illustrate the presence of water, organic matter, and mineral matter in milk, the separation of curd and whey, the presence of albumen and milk sugar in whey, the separation of butter fat from cream, the presence of casein in butter, tests to distinguish between butter and oleomargarine, and the effect of heat and cold on the keeping quality of milk.

Outline of course in nature study, L. H. MILLER and E. B. BABCOCK (*Training Dept., Los Angeles Normal School*, 1906, pp. 16).—The general purpose of the nature-study work in this school is "to bring the child and nature into the most vital contact possible."

The course includes work with plants, animals, and nature-study literature. Both wild and cultivated plants are studied—to be able to recognize them, to know what they do, to become familiar with the life history of certain ones, to acquire knowledge of the cultivation of common vegetables and flowers, and to take up eventually some of the more special phases of plant production. The means employed in acquiring this information are the school garden, home gardens, and field trips and observations.

A like comprehensive study of the more common animals—birds, mammals, toads, insects, etc.—and the proper care and treatment of them, is taken up in the schoolroom, at home, and on trips afield.

The outline of nature-study work in detail was prepared by B. M. Davis, and includes work for each term and grade through the eight years of common school work. The work of the seventh grade consists largely of experiments in

elementary agriculture on such topics as soils, soils and water, soil and the plant root, and fundamentals of plant physiology. This work is supplemented by excursions in the field and the study of the great agricultural industries correlated with United States history. In the eighth grade laboratory and text-book work in human physiology takes the place of similar work in agriculture, but the garden work, with varieties of plants for the purpose of showing plant improvement, seed selection, crop rotation, green manures, and soil inoculation, is continued.

The outline includes numerous references to text-books and other literature germane to the topic under consideration.

Practical nature study, F. E. BROOKS (*W. Va. School Jour.*, 35 (1907), No. 10, pp. 9, 10).—A description of the shrew, its habits, and economic importance.

Direct methods of studying nature, LULIAN J. CLARKE (*Nature-Study Rev.*, 2 (1906), No. 9, pp. 302-310).—This article, reprinted from *The Windsor Magazine*, is a description of the nature-study work at the James Allen's Girls' School, Dulwich, England. This is an endowed secondary school, and the girls in it are not being trained for any particular profession.

School garden work has been carried on for many years and has developed to an area containing plats owned by more than 140 girls. Some of these are plats containing families of plants, others are flower gardens, vegetable gardens, gardens showing plant associations, etc. There is also a plant laboratory with glass roof. The students do the practical work in the gardens, and study the relation of insects to pollination and fruiting, the classification of plants, which is greatly facilitated by the plats containing orders or families of plants, cookery in connection with the growing of kitchen vegetables, soils and the use of legumes and fertilizers, fruits, methods of seed dispersal, ecology, and other things relating to the physiology and pathology of plants.

Hints on making nature collections in high schools, W. H. MULDEW (*Ontario Agr. Col. and Expt. Farm Bul.* 134, pp. 32, figs. 20).—This bulletin is in its second edition, having been revised by S. B. McCreedy, of the Macdonald Institute. It contains an outline for nature-study work in public schools, suggestions for phenological observations, for making live collections, collections of pressed plants, seeds, fruits, wood, insects, historical specimens, etc.

Nature-study work with insects, C. F. HODGE (*Nature-Study Rev.*, 2 (1906), No. 8, pp. 265-270, figs. 2).—Suggestions for nature-study life history work with insects and a description of suitable cases for preserving life history sets.

Nature studies with birds for the elementary school, R. W. HEGNER (*El. School Teacher*, 7 (1907), No. 6, pp. 348-354).—The subject of bird protection is considered, together with reasons for the absence of birds and how to attract birds. A bibliography is appended.

A day's work in bird-land, EDNA R. THAYER (*Nature-Study Rev.*, 2 (1906), No. 9, pp. 289-295).—This is a record of observations on the feeding habits of birds conducted under the direction of C. F. Hodge, of Clark University, by students at the biological station at the University of Indiana at Winona Lake, in July, 1906. Relays of students placed themselves in position to observe constantly from daylight to dark of one day the nests of an orchard oriole, a pewee, a phoebe, and a wren.

In the nest of the orchard oriole were two young birds which during the 15 hours and 17 minutes of observation were fed 69 times, 5 times only by the male bird. The food consisted principally of locusts and green caterpillars.

The pewee's nest contained 2 eggs, so the food collected by the female was for herself. During the day she caught 208 insects, and spent a total of 5 hours and 35 minutes in incubation, the average length of resting on the nest

being 10 minutes. The male visited the nest frequently and devoted himself to keeping away sparrows and other intruders.

The nest of the phoebe contained 2 young birds 4 days old. The female left the nest at 4.20 a. m., and between that time and 7 p. m., when it began to rain, the birds fed their young 260 times.

Observations on the wren's nest were not begun until 9.20 a. m., and ended at 6.46 p. m., when it began to rain. There were 5 young birds about 3 days old in the nest, and in the 9 hours and 26 minutes under observation they were fed 113 times, 91 times by the male and 22 times by the female. In most cases the male gave the food to the female who then distributed it among the young. The food consisted of cutworms, grasshoppers, cabbage worms, and black insects which were not identified. This nest was observed again 4 days later from 4.24 a. m. to 7.38 p. m. On this day the female did not brood her young so much, but fed them 130 times out of the 230 times that they received food.

MISCELLANEOUS.

Nineteenth Annual Report of Alabama College Station, 1906 (*Alabama Col. Sta. Rpt. 1906, pp. 36*).—This includes the organization list of the station, a financial statement for the fiscal year ended June 30, 1906, and reports of the director and heads of departments covering the work of the station during the year.

Nineteenth Annual Report of Michigan Station, 1906 (*Michigan Sta. Rpt. 1906, pp. 93-337*).—This contains a financial statement for the fiscal year ended June 30, 1906, reports of the director and heads of departments on the work of the station during the year, meteorological observations noted elsewhere, and reprints of Bulletins 232-238 and Special Bulletins 34 and 35.

Twenty-fourth Annual Report of New York State Station, 1905 (*New York State Sta. Rpt. 1905, pp. 405*).—The report comprises a financial statement for the year ended September 30, 1905, a list of periodicals received by the station, meteorological observations noted elsewhere, and reprints of most of the bulletins of the station issued during the year.

Experiment Station Work, XXXIX (*U. S. Dept. Agr., Farmers' Bul. 276, pp. 32, figs. 2*).—This number contains articles on the following subjects: Improvements in peach growing; mulberries; alfalfa in the eastern States; oat culture in the South; improvement of grass land; succotash as a soiling crop; tankage and bone meal for hogs; grinding corn for hogs; dips as lice killers; digestibility of fish and poultry; honey vinegar; and the farm woodlot.

Yearbook of the German Agricultural Association, 1906 (*Jahrb. Deut. Landw. Gesell., 21 (1906), pp. XIX+436+422*).—A report of the proceedings of the three meetings of this association held during the year. There is also an account of the twentieth movable agricultural exhibit of the association.

NOTES.

Colorado College and Station.—F. E. Brooks, a member of the last Congress, and J. L. Brush, formerly lieutenant-governor of the State, have been appointed on the State board of agriculture, in succession to P. F. Sharp and Harlan Thomas. B. F. Rockafellow has been elected president of the board. The courses in veterinary science and electrical engineering which were discontinued on account of lack of funds are to be reinstated.

An appropriation was made by the legislature for the purchase of land for the college and station, and the use of 10 per cent of the funds arising from the sale of lands under the original Morrill Act was authorized for the same purpose. The station will receive \$27,500 for the ensuing biennium, provision being made for work in animal, plant, and fruit industry, horse breeding, and diseases of live stock. The fruit studies on the Western Slope are to be continued, and additional work is planned with potatoes at Greeley.

Successful short courses were held during the winter in forestry, horticulture, and domestic science. H. M. Cottrell has been placed in charge of the extension work and farmers' institutes, being succeeded as animal husbandman by G. E. Morton, of the Wyoming University and Station, as previously announced.

Florida Station.—Everest J. Macy, a graduate of Earlham College, has been elected assistant chemist, and began his duties May 1. William Hess has been appointed gardener.

Illinois University and Station.—L. H. Kerrick, for four years a trustee and on the day before his death elected president of the board, died March 13.

Indiana Station.—The State board of agriculture has granted the station the sole use of one of the large buildings on the State fair grounds. The building will be remodeled and equipped to accommodate the station exhibits and a working dairy, and to provide an auditorium for illustrated lectures. It is hoped that a large number of the people of the State will be brought into close touch with the work of the station in this way.

Kansas College and Station.—An act was passed by the recent legislature authorizing the board of county commissioners of any county in which a substitution has been or shall be established by the board of regents of the college to purchase, on the petition of one-half of the legal voters of the county, a tract of land not exceeding 320 acres, at a cost of not over \$5,000, for lease or donation for experimental purposes, and to levy a tax in payment. Under another recent law, which provides for the nomination of the State dairy commissioner by the secretary of the State board of agriculture, the director of the station, and the professor of dairy husbandry, J. C. Kendall, of the North Carolina College and Station, has been appointed. M. D. Snodgrass, a recent graduate and assistant in crop production, has been appointed assistant in the Alaska Stations and assigned to the breeding station at Kadiak Island, to begin work June 1. C. K. McClelland, of the Farm Management branch of the Bureau of Plant Industry, has been appointed superintendent of the branch station at Fort Hays.

Louisiana Stations.—In cooperation with the cerealist of the Bureau of Plant

Industry of this Department a large number of varieties of rice have been planted at Crowley and fertilizer trials are being carried on. Considerable local interest is being manifested in this work, and it is probable that the next legislature will make provision either for extending it or for establishing a permanent rice experiment station. J. B. Garrett has been appointed acting assistant director at Calhoun during the leave of absence of J. G. Lee.

Maine Station.—Dr. Raymond Pearl, instructor in zoology in the University of Pennsylvania, has accepted an appointment as biologist, to begin with the next academic year. The appointment is made under the provisions of the Adams Act, and the work will consist entirely of research in plant and animal breeding. Special attention will be devoted to an investigation of the principles of inheritance in poultry, the practical phases of which have already been extensively developed at the station.

Maryland Station.—*Students' Herald* notes the resignation of W. B. Thurston as assistant dairyman to enter commercial work.

Massachusetts College and Station.—Merritt I. Wheeler, trustee for many years, died April 7, and Hon. Frank Gerrett, of Greenfield, has been appointed on the board. H. J. Franklin and J. N. Summers have been appointed assistants in entomology. The former is to carry on the study of cranberry insects, with headquarters at Wareham. At a recent conference with representatives of the Massachusetts Cranberry Growers' Association much interest was manifested in the experiments under way, and the association volunteered to provide, at its own expense, a bog for use in the work. W. E. Dickinson has been appointed assistant chemist in connection with the fertilizer inspection, dating from July 1. C. P. Halligan, assistant horticulturist, has resigned to accept a similar position at the Michigan Agricultural College.

Missouri University and Station.—J. M. Stedman, entomologist, has been granted leave of absence for 17 months, a part of which will be spent in research at the Naples Zoological Station. C. H. Hechler, assistant in animal husbandry, has resigned to enter commercial work.

New Hampshire College and Station.—W. H. Pew, a graduate of the Iowa College, has been elected assistant professor of animal husbandry in the college and animal husbandman in the station, and F. Rasmussen, assistant in dairying in the Iowa College and Station, has been elected associate professor in dairying in the college and dairyman in the station. A department of botany has been organized in the station, in charge of Charles Brooks as botanist.

New Jersey College and Stations.—*Breeders' Gazette* states that F. C. Minkler, a graduate of the Iowa College, has been elected professor of animal husbandry. Charles S. Cathcart, several years ago a member of the station staff, and since that time in fertilizer work, has been appointed chemist.

New Mexico College and Station.—R. R. Larkin and Hiram Hadley have succeeded H. B. Holt and G. A. Richardson on the board of regents. P. D. Southworth, a graduate of the Minnesota College of Agriculture, has been appointed assistant in animal husbandry in the college and station. Courses in civil and electrical engineering have been added to the college curriculum, and a department of irrigation engineering has been organized under the direction of B. P. Fleming, of this Office, as previously announced. W. O. Bryant will have charge of the irrigation work until July 1. Farmers' institutes have been held during the winter and spring in practically all of the agricultural districts of the Territory, and farmers' institute societies have been organized in most of the localities.

Cornell University.—According to a recent note in *American Agriculturist*, an investigation in farm management is being conducted by M. C. Burritt

under the direction of T. F. Hunt. The object of the work is to determine not only what incomes are received from investments of from \$6,000 to \$20,000, but also, if possible, what classes of investments give relatively the best returns.

We note from press reports the dedication of the new buildings of the college of agriculture on April 27, in conjunction with the celebration of the centennial anniversary of the birth of Ezra Cornell. Addresses were delivered by President Schurman, Governor Hughes, Ex-Governor Woodford, N. J. Bachelder, master of the National Grange, and Dean Bailey.

North Carolina College and Station.—At the recent session of the legislature the management of the college and station, previously assigned to the State board of agriculture, was vested in a new board of control of 16 members. This board is entirely distinct from the State board of agriculture, which will continue to direct the experimental work of the State department of agriculture.

Pennsylvania College and Station.—B. E. Fernow, who had temporarily accepted the professorship of forestry, has been appointed dean of the faculty of forestry at the University of Toronto, where, according to a note in *Science*, it is proposed to organize the most complete system of forestry education on this continent. It is expected that a large forest reservation will be set aside for the use of the Toronto school, and university extension work of the broadest kind is contemplated.

M. H. Pingree and P. W. Flint have resigned from the station staff, and G. C. Watson, agriculturist, has been given leave of absence until August 1, 1908. F. S. Putney, assistant in agronomy and animal industry, has been transferred to the division of animal nutrition. Recent appointments include, in the station, Albert R. Merz as assistant chemist and Robert A. Liehtenthaler as assistant in animal nutrition; and in the college, John P. Stewart as assistant professor of experimental horticulture, who is making a special study of the apple in Pennsylvania.

Texas College and Station.—E. C. Green, instructor in horticulture in the college and assistant horticulturist of the station, has been placed in charge of the Texas Plant Introduction Garden at Brownsville, a branch of the Bureau of Plant Industry of this Department.

The total appropriation for the college and station for the ensuing biennium aggregates \$346,370, by far the largest appropriation in the history of the college. Of this amount \$2,000 is for publications, \$14,000 for the two substations. The remainder is for repairs and new buildings, including a farm-implement building to cost \$4,000, a dormitory, an engineering building, a natatorium, a veterinary hospital, and live-stock sheds. The increased appropriation will enable the college to strengthen much of the work already under way and to establish new departments, especially a department of agricultural extension work.

C. H. Alvord has been elected to the chair of agriculture in the college, vice F. S. Johnston, resigned. Mr. Alvord was assistant professor of agriculture at the college in 1901 and 1902, and has since been engaged in farming in Michigan.

Utah College and Station.—The Utah legislature adjourned March 22 after a session during which a determined effort to unite the college with the State university, either by consolidation on one site or by means of a joint board with separate maintenance, was unsuccessful. The appropriations for both the college and station were much reduced. For the next biennium \$90,000 was appropriated for the college, \$10,000 for investigations in dry farming, and \$5,000 for investigations in irrigation and drainage, in cooperation with this Office. Hon. W. S. McCormick, who has served as president of the board of trustees since the

organization of the college, has resigned. J. Q. Adams, of Logan, and Mrs. A. W. McCune, of Salt Lake, have been appointed on the board.

Vermont University and Station.—Hon. G. G. Benedict, a trustee for 42 years, and also secretary of the board, died April 8, aged 80 years. Joseph Battell, secretary of the American Morgan Breeders' Association, has deeded to the United States, for use in the cooperative work in horse breeding now being carried on by this Department and the station, a farm of approximately 300 acres near Middlebury, and about 35 miles south of the station. The farm is equipped with a large modern horse barn, and the cooperative work will be transferred from Burlington and its volume greatly augmented in the near future. C. G. Pringle, the veteran botanical collector, has been appointed to make a collection of solanaceous plants in Mexico for the station, in connection with the study of disease resistance. C. R. Pettis, State forester for New York, and in charge of the Adirondack forest seedling nurseries, has been appointed consulting forester to the station.

West Virginia University.—A summer school, beginning June 24 and closing August 3, is announced. Among the 25 courses of study offered are nature study, elementary agriculture, principles and methods of education, and school supervision.

Wisconsin University and Station.—H. L. Russell, professor of bacteriology in the university and bacteriologist to the station, has been appointed dean of the college of agriculture and director of the station, to succeed W. A. Henry at the beginning of the college year. Among other appointments and promotions announced are, as associate professor, D. H. Otis, in animal nutrition; as assistant professors, R. H. Denniston in botany, J. G. Moore in horticulture, and C. A. Ocock in agricultural engineering; as instructors, G. M. Reed in botany, James Milward in horticulture, and Conrad Hoffman in agricultural bacteriology; and as assistants, H. D. M. Jollivette in botany and Matthew Michels in butter and cheese scoring. In the announcement for the university summer school it is stated that Dean Henry will conduct a class in agriculture for teachers in the public schools.

The station is conducting a vigorous campaign against tuberculosis in the 100,000 dairy herds in the State. Existing laws provide for the inspection of cattle before entering the State, and a bill has been introduced into the legislature providing for the testing of all cattle before sale. Instruction in the use of the tuberculin test has been given to about 1,200 former agricultural students who compose the membership of the Wisconsin Agricultural Experiment Association. While under the laws regulating veterinary practice these students are not permitted to collect fees, they are nevertheless rendering much assistance.

Plan for County Experiment Stations.—A bill has been introduced into the Missouri legislature which authorizes any county court, on the petition of 50 freeholders or the resolution of any agricultural or horticultural society in the county, to establish and maintain an experiment station. This may be located at the county farm, or other land may be leased. Supervision is to be vested jointly in the county court and the State experiment station, and the work proposed is mainly that of demonstration.

A Mexican Botanical Station.—In a recent issue of *Plant World* an account is given of the botanical station and rubber laboratory recently established on La Zaenalpa plantation, Chiapas, Mexico, under the direction of Dr. P. Olsson-Seffer. The larger part of the land is to be devoted to rubber, including experimental plats of *Castilloa* and a collection of all known rubber-producing plants, and the remainder will be used for the more unusual representatives

of Mexican flora and many foreign tropical plants. In conjunction with the station work experiments in hybridizing the coffee tree will be conducted on a neighboring plantation.

Agricultural College for Hawaii.—An act providing for the establishment of a college of agriculture and mechanic arts has been passed by the Territorial legislature of Hawaii and approved by the governor.

Credits in Agriculture at Columbia University.—Dean James E. Russell, of Teachers' College, announces that arrangements have been made to accept at full value for degrees in Columbia University work done in agriculture at any of the leading agricultural colleges. This is done with a view of fitting students for the position of director, principal, etc., in training schools for agricultural teachers.

Board of Food and Drug Inspection.—Dr. Frederick L. Dunlap, an instructor in the University of Michigan, has been appointed associate chemist in the Bureau of Chemistry, and will be a member of the board of food and drug inspection, which will consider all questions arising in the enforcement of the pure food law. The other members of this board are Dr. H. W. Wiley, chairman, and George P. McCabe, solicitor of the Department.

Plans for Irrigation Congress.—The Fifteenth National Irrigation Congress is to be held in Sacramento September 2-7. Its purpose is announced as being "to promote the development of wise and beneficial national irrigation and forestry policies, as well as to provide for discussions of practical details of irrigation and forestry." The plans include an interstate exposition of irrigated land products and forestry and a 1,000-mile excursion through the Sacramento Valley to enable delegates to study California farming and irrigation.

International Dairy Federation.—A detailed programme has been received for the third international congress of dairying, to be held, as previously announced, at The Hague September 16 to 20, 1907. The congress will be divided into sections of dairy legislation, hygiene, and industry. Its meetings will coincide with the national agricultural exhibition, which will include a subdivision devoted to the dairy industry, open to exhibits from all countries. Excursions have been arranged to the butter-control station and state dairy station at Leyden, the serotherapeutic institute at Rotterdam, the laboratory of bacteriology at Delft, and other points of interest. Additional information can be obtained from the secretary, Dr. A. J. Swaving, 88 Lange Voorhout, The Hague.

Institute of Agriculture at Rome.—According to a note in *Mark Lane Express*, the preliminary work for the organization of the National Institute of Agriculture at Rome, founded by King Victor Emmanuel, is proceeding actively. Great Britain, the United States, France, and other countries have promised their cooperation in the functions of the institute. A building is in course of erection and the first meeting of the general assembly is planned for 1909.

Department of Agriculture for Buenos Ayres.—Plans are under way for the establishment of a department of agriculture and animal husbandry in the Province of Buenos Ayres. A bill introduced into the local legislature provides for the establishment of such a department January 1, 1908, under the direction of the minister of public works, to consist of divisions of agriculture and animal husbandry. Six practical schools of agriculture and animal husbandry, which will also give instruction in forestry, are provided for, and an extensive inspection service. A commission of 5 members, one of whom must be an agricultural engineer and another a veterinary surgeon, is to be appointed by the president to determine the duties of the department, lay out a course

of study for the agricultural schools, and draw up regulations for the control of animal and plant diseases.

Investigation of Agricultural Instruction in Great Britain.—The president of the Board of Agriculture and Fisheries has, according to *Nature*, appointed a committee to inquire whether the provisions now made for scientific and technical instruction in agriculture in England and Wales are satisfactory and sufficient, and if not, in what manner they may with advantage be modified or extended. Prof. T. H. Middleton and Prof. W. Somerville are members of the committee.

Agricultural Students in German Universities.—*Chemiker Zeitung* states that the total number of matriculated students in the German universities is 44,942, of whom 985 or about 2 per cent are enrolled in agricultural science courses. Of these 573 or 58 per cent are from foreign countries, although the foreign students constitute but 9 per cent of the total enrollment.

Agricultural Education in Chile.—A practical school of agriculture was opened at Talca June 29, 1906, under the directorship of Carlos Echeverria Cazotte. The school was started with an appropriation of \$71,000 for land and \$28,000 for equipment and maintenance. The director is also professor of agriculture and zootechny, and is assisted by professors of forestry, physical and natural sciences, engineering, viticulture, and the common elementary branches. Twenty-four students were enrolled at the opening of the school.

Schools of Agriculture in Servia.—The consul at Belgrade, Servia, reports in the *Monthly Consular and Trade Reports* for February as follows:

“There are, in addition to the experimental farms at which instruction in agricultural subjects is given, three agricultural schools in Servia, as follows: (1) School of general agriculture at Kraljevo, (2) school of viticulture and arboriculture at Bukovo, and (3) school of agriculture at Sabac. Near Belgrade the government has a model farm, on which the best methods of farming are shown to the peasants and experiments are made as to the best grains, etc. In 1902 an experimental farm was established at Dorbricevo for the purpose of breeding animals. The government gave 1,000 hectares for this farm. After the almost total destruction of the vineyards by the phylloxera in 1882 the government established vineyards in order to restore this industry by experimenting. There were in 1905 six of these experimental vineyards. A considerable quantity of vines are given gratis to the cultivators, and those vineyards that resist the phylloxera are exempt from taxes for ten years.”

At Smederevo (Semendria) there is also a dairy farm, established in 1903, which manufactures three grades of excellent cheese and offers special courses of instruction annually.

Agricultural Education Abroad.—According to the annual report of the Board of Agriculture and Fisheries, during the fiscal year 1906 the grants to agricultural education in Great Britain aggregated about \$420,000. The number of students has increased from 23,000 to 34,000 in the last two years. A widening of public interest in the study of agriculture is reported, and it is stated that farmers are coming to rely more and more upon the agricultural institutions for assistance in the solution of their problems.

According to the *New Zealand Official Yearbook* for 1906, the Canterbury Agricultural College, at Lincoln, now has an endowment of 62,000 acres of land, which has a rental value of \$7,290, and possesses extensive buildings and an experimental farm. The institution offers a good course in the science and practice of agriculture, which is accepted as a part of the curriculum leading to the degree of B. S. in agriculture at the University of New Zealand. The college accommodates 40 students. A report on the public schools for 1904 shows that 47 out of 725 schools gave instruction in elementary agriculture.

The *Wiener Landwirtschaftliche Zeitung* is authority for the statement that in 1905-6 there were 190 schools in Austria giving instruction in agriculture and forestry. This is an increase of 4 over the previous year, the new schools being the agricultural winter schools at Spittal-on-the-Drau, in Carnithia, and at Lubeza, in Galicia, the elementary forestry school at Klagenfurt, in Carnithia, and the farm school at Dignano, in Istria. The 190 institutions include 2 high school institutes, 3 agricultural academies, 9 agricultural high schools, 5 forestry high schools, 12 high schools for viticulture, pomology, and horticulture, 1 high school for the brewing industry, 41 farm schools or elementary agricultural schools with one-year courses, 73 agricultural winter schools, 10 elementary forestry schools, 16 dairy and housekeeping schools, 24 elementary special schools for horticulture, pomology, viticulture, hop culture, alpine farming, and apiculture, 2 brewing and 2 distillery schools.

The attendance at the royal agricultural high school at Vienna for 1905-6 was 668 for the first semester and 611 for the second semester. In the first semester 590 of the students were regular and 78 special. In the second semester 554 were regular and 57 special. About 48 per cent of all the students were enrolled in forestry courses.

A chair of agricultural-technological chemistry has been established at the polytechnic high school, Copenhagen, and Dr. Orla Jensen has been appointed to the position. The studies will be devoted principally to the utilization of milk and meat, and will include (1) the production and chemistry of milk, the bacteriology of milk, its uses for food, milk powder, casein, cream, butter, and cheese, and dairy associations, and (2) the production of meat and bacon, methods of pickling or salting, chemistry of pickling or salting, canned meat products, and the arrangement of slaughter houses for pigs.

The Queensland Agricultural College has been giving training courses in agriculture for teachers in State schools, and as a result some instruction in agriculture has been given in a number of schools. A movement has also been started to offer prizes for school gardens in the different districts of Queensland, and the Queensland department of agriculture has agreed to instruct its experts to visit country schools as far as practicable and give the pupils and teachers guidance and help.

The practical school of viticulture, established in 1893 at Praz sur Vevey, was discontinued in 1905 owing to the fact that the sons of the vine growers could not be spared during the busy season. In place of the regular school the Canton of Vaud has conducted successful short courses in arboriculture, viticulture, and the utilization of fruits. Such courses are announced for the autumn of 1907.

Y. M. C. A. Agricultural Clubs.—The educational department of the international committee of Young Men's Christian Associations has entered upon a campaign to encourage the associations in different parts of the country to start boys' agricultural clubs and boys' gardens as means of employing profitably the time of the younger members when pleasant weather out of doors attracts them away from the association rooms. A leaflet has been published giving suggestions for organizing the clubs and conducting the gardens.

Department of School Gardens.—The New York University, in its announcements for the summer school of 1907, includes an announcement for the department of school gardens under the direction of H. G. Parsons, who conducted successfully a similar department in 1906. It is proposed to combine lectures and laboratory work on soils, plants, and other technical matters relating to gardening, with a study of problems concerning the handling of children's gardens and the social features of such work.

Miscellaneous.—W. T. Horne has, according to a note in *Science*, been appointed head of the department of plant pathology in the Central Agricultural Experiment Station of Cuba.

Percival Maw has been appointed to the chair of forestry and estate management at the Royal Agricultural College, vice F. C. McClellan.

The *Wiener Landwirtschaftliche Zeitung* reports the death, on February 17, of Otto Kambersky, director of the Agricultural Experiment and Seed Control Station and of the agricultural winter school at Troppau.

A recent number of the *Deutsche Landwirtschaftliche Presse* notes the death, on March 17, of Dr. Rudolf Aderhold, director of the Imperial Biological Institute for Agriculture and Forestry at Dahlem.

La Semaine Agricole notes the death of Houdet, director of the national dairy school at Mamirolle, Doubs, since 1902, and states that he is succeeded by B. Kohler, at present departmental professor of agriculture in Doubs.

Cornell Countryman states that Modesto Quiroga, a recent graduate of Cornell and now professor of agronomy in the national university at Buenos Ayres, has been appointed inspector of agricultural schools in the Argentine Republic. Lupercio Fagundes, also a recent graduate, has been appointed vice-director of the experimental substation for rice investigations at Moreira Cezar, São Paulo, Brazil.

The section of agriculture and public works of the imperial ministry of Alsace-Lorraine has decided to establish on June 1, at Metz, a branch station of the experiment station at Kolmar. Dr. Hubert Rössler, assistant in the agricultural division of the Kali Syndicate, has been appointed director of the station.

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau requests and remittances should be directed to the Chief of the Bureau. The price of the Record is \$1 per volume, or 10 cents per number. The prices of other technical publications are given in the list above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XVIII.

JUNE, 1907.

No. 10.

The celebration of the semicentennial of the Michigan Agricultural College the week of May 26 was an occasion of national importance. It marked the anniversary of a significant and far-reaching departure in American education. While primarily the fiftieth anniversary of the establishment of the Michigan College, in a larger and more important sense it was the anniversary of a new type of education which has ripened into a great national system, fostered alike by the Federal and State governments, and already become one of the most potent influences in the educational world. It was the birthday of agricultural education—of an attempt to relate education more closely to the practical needs of life.

It was fitting that such an anniversary should be commemorated by the bringing together of men prominent in agricultural and industrial education and research from all over the Union, as well as the army of graduates and friends of the college. It was more than local, and such a representative gathering betokened the broad significance of the event celebrated. Its national character was further evidenced by the attendance of the President of the United States, the Secretary of Agriculture, and the Commissioner of Education, with inspiring addresses upon the influence and the mission of the land-grant colleges in the system of American education. It was a great day for the Michigan Agricultural College, but no less a day of triumph for agricultural education as a whole. The widespread public attention which it attracted placed the agricultural colleges in a new and more favorable light and assigned to them a more conspicuous place in the field of technical education.

Such an occasion, with its review of the history of this great movement, its lessons from the past, its survey of what has been accomplished in a material way and in the shaping of public sentiment, its forecast of the future with higher ideals and broader and more liberal plans for development, is stimulating and helpful to the land-grant colleges as a whole. It can not fail to give a larger conception of the mission and influence of these institutions and a clearer view of what education should be.

And for the pioneer institution it was an occasion for rejoicing and congratulation and for tribute to the success of its honorable career. Aside from delegates from colleges all over the Union, some twenty-five hundred of its sons and daughters gathered to do it honor, and the large meetings held in the tent provided for the occasion were live with enthusiasm and reminiscence and ardent in appeal for the preservation of old landmarks.

It is a notable achievement to have taken a leading part in "building new avenues along which knowledge is approaching more closely to human needs;" and to do this in the face of unbelief and dogmatic opposition has required a tenacious faith and an abiding courage. In planning and conducting this celebration of its anniversary, the Michigan Agricultural College has added to the debt of gratitude which all the colleges of the system owe to it, for it has shared with them the appreciation, the benefits, and the inspiration which arise from such a great national demonstration.

There was perhaps no more striking feature of the celebration than the recognition of the real significance attaching to the founding of this first agricultural college. In the light of fifty years of experience, the influences which have sprung from this initial step upon the educational conceptions of the whole country were weighed and meted out. It was naturally a day of reckoning, and while the various speakers did not withhold criticism of methods and standards and conceptions prevailing at various stages of development, they were generous in their praise of the final outcome. They paid high tribute to the educational significance of the movement.

President Wheeler, of the University of California, characterized the inauguration of the agricultural college as "a weird undertaking and audacious, unapproved of the elders," but he credited these colleges with having "embodied a fresh and vitally new idea of education and what it is all about." The mechanism of education had become largely a formal instrument of discipline. "The significance of the agricultural college," he said, "for the whole trend of American education was its naïve effrontery in frankly seeking for life training a new connection with real life use; and this significance exceeds in service to the nation even the weight of the benefits wrought for the tilling and the tiller of the soil"—a statement so broad in its character that from a less reliable or a partisan source it might be regarded as a possible exaggeration.

Secretary Wilson described the establishment of the agricultural college as one of the significant and far-reaching events of the nineteenth century. In these institutions the foundation of agricultural education and research have been laid "to prepare the farmer for his life work, provide agricultural literature, and lift the tiller of

the soil to a higher level of efficiency as a producer and a citizen." He declared that these colleges have broadened the minds and strengthened the arms of the farmers, helped them into a class by themselves among tillers of the soil, and dignified their calling.

Commissioner Brown, of the Bureau of Education, expressed his high appreciation of the land-grant colleges and emphasized their importance in the general educational system of the country.

Similar utterances by other speakers assigned to the agricultural college a high place among the influences which have been active in developing technical education; and Doctor Jordan said: "It is generally conceded that no instance is on record where technical knowledge has been brought into such close and practical touch with the people as has been done for our agriculture during the past twenty-five years."

The boldness and novelty of the undertaking become more apparent when the conditions of the times are remembered. In 1850 Michigan was in things cultural still the frontier—a pioneer country. Its population had not yet reached 300,000, less than the present population of a single city within its borders; and its farms numbered 34,000, embracing only about 4,000,000 of its 37,000,000 acres.

At that time the public school system of the country was but feebly developed, and the responsibility of the States for education was only recognized to a quite limited extent. The teaching of natural science in the higher institutions was quite restricted, and opposition to its introduction had hardly begun to be overcome. Technical schools for other branches were almost unheard of, and manual training as a branch of the educational system had not begun to receive consideration. Without the example of a successful agricultural college in America, and without the prestige of precedent as an argument for such action, the constitution adopted in 1850 committed the State to the policy of establishing and maintaining an agricultural college where the natural sciences in relation to agriculture should be taught. And five years later the State appropriated \$56,000, a large sum for that time, to carry this provision into effect.

The question naturally arises as to the source from which the inspiration came for this action, the influences which had been working, and what supplied the courage and conviction essential to such an unprecedented step. There seems to have been a prevalent idea even at an early day that science was to be of great aid and value to the fundamental industry of agriculture. There had been considerable agitation of agricultural instruction and agricultural schools in the East, and the experience of Germany had been given considerable publicity in this country. There were many who believed in agricultural instruction, and it appealed to the public generally as being a practical form of education whose benefits could be readily appre-

ciated. But even so, the taking of so important and novel a step by this frontier State was a bold and radical departure from the traditions of education.

The State Agricultural Society was organized in 1849, and, as agriculture was the great industry of the State, the society had the support and cooperation of the leading men, as well as of the farmers themselves. Secretary Butterfield, in describing the influences that have made the college what it is, credited the Agricultural Society with having been a very potent influence in this direction, and with having secured funds for the establishment of the college in 1855, after repeated appeals to the legislature. Two years later, in May, 1857, the college opened its doors to students.

The anniversary exercises brought out much of interest regarding the early history of the college, which showed how humble and crude were its beginnings and how great the obstacles against which it had to contend. One session was given up to the "builders of the college," with addresses upon the men and the conditions of the early days. The conditions surrounding the new institution are well illustrated by a statement from the address of President Monroe, of the State board of agriculture, who spoke for the college and the students of '57 to '60. "The college was a typical Michigan pioneer," he said, "in starting in the woods, in opening up roads, in logging and burning green timber—much of it in the wet season of the year—the pulling of green stumps and digging where an ax was as important as the spade or the shovel." The transformation in the college and its surroundings which fifty years have wrought is typical of the progress and upbuilding of agricultural education which have taken place in that period.

From the nature of the occasion, interest centered largely around matters historical, both at the anniversary celebration and the convention of the Association of American Agricultural Colleges and Experiment Stations, which was held in connection with it. The exercises took on a historical cast and there was much discussion along the lines of the unwritten history of agricultural education and research in this country, the agencies and influences that have been operative at different stages of development, and the sources from which the leaders drew their inspiration.

These discussions served to show how little systematic study has been given to the movement for these land-grant institutions in connection with the condition of the times, the influences and tendencies then in evidence, and the individual efforts of prominent exponents working in different parts of the country. The question was even raised as to the causes which first led Mr. Morrill to propose national legislation, for the opinion seemed prevalent that the ideas embodied in the measure which he so persistently and untiringly pressed

through several sessions to final passage were not entirely original with him. It developed that several men in different parts of the country were agitating the establishment of such institutions and that Mr. Morrill was in touch with some of them.

These historical matters developed a somewhat unexpected amount of interest and a desire for thorough and systematic study upon the early history of agricultural education in this country. The discussion opened the way for a line of inquiry that would be most interesting.

The development of the pedagogy of agriculture was likewise an interesting topic of discussion, which was started at the meeting of the Society for the Promotion of Agricultural Science with a paper by Dr. A. C. True. As indicating how slowly the teaching of this new subject worked out, it was mentioned that as recently as 1895, when a standing committee on methods of teaching agriculture was organized by the association, the agricultural departments of the colleges were relatively weak and ill organized and were not taking due advantage of the rapidly accumulating pedagogical material afforded by the experiment stations. The first report of this committee in 1896 pointed out that "there exists at present in this country no standard for instruction in agriculture. There is a bewildering variety as regards the topics taught, the time devoted to each topic, the order in which the different topics occur in the course, the relative amount of class-room work and laboratory or practical exercises, etc. Granting all that ought to be conceded because of local conditions, it is nevertheless obvious that general progress in the teaching of agriculture in college courses can hardly be expected until there is greater uniformity in planning and conducting the courses of study in this subject."

Not until the nineties did it begin to be understood by college presidents and trustees that the old policy of waiting to establish adequate agricultural courses until multitudes of students were clamoring for them was wrong. Experience soon demonstrated that when the agricultural courses were made respectable as regards faculty and equipment, a reasonable number of students would take them.

The passage of student labor as a part of the agricultural course, one of the early traditions of the agricultural colleges, was a fruitful subject of reminiscence among earlier students, and was generally looked upon as having failed to accomplish its purpose owing to failure to conceive the real pedagogic purpose and method. "Nobody seemed able to devise a good system of educational labor, and the whole scheme of student labor as a part of a college course in agriculture fell into discredit and disuse."

Another important transition which has come as the result of accumulated experience is the size of the teaching force considered

necessary for the strictly agricultural subjects. In comparison with the old-time professor of agriculture who covered the whole range of agriculture and frequently had other duties as well, the present differentiation stands out in strong contrast, making for increased specialization and efficiency. In many cases much of the field now occupied by agricultural instructors was formerly covered by the teachers of the primary sciences, often resulting in a divorce of science and practice. The natural consequence was that the instruction in agriculture was often given over to practical men without much scientific training. There was comparatively little attention given to the building up of agricultural courses on a sound pedagogic basis; and agriculture as a subject of college instruction fell into more or less contempt among educators and students.

In most of the colleges the agricultural faculty is increasing rapidly, and the old-time professor of agriculture has become as much of an anomaly at the present day as a professor of natural science would be in a college of science.

As showing the change in material equipment and facilities for instruction, an appeal was read from Prof. Levi Stockbridge's report for 1873 for "a lecture room, suitably furnished with appropriate emblems and diagrams, and adjoining cabinet and museum rooms supplied with everything needed to make the instruction of the professor of agriculture as interesting and useful as possible." Such an appeal seems to-day almost pathetic. The special building for agriculture has become almost a commonplace and an accepted necessity at the agricultural college, with laboratories of various kinds and rooms for every description of indoor work. Incidentally it was mentioned that the new agricultural building at Cornell contains 47 rooms for dairying alone.

Along with these changes in methods of teaching, development of the teaching force, and the like, has come as a lesson of the past a higher and broader conception of the mission of these colleges and the functions of education. This has been an important development, and one to which attention was naturally called on such an occasion.

President Roosevelt in his address, in speaking of the mission and the limitations of these institutions, laid down the broad principle that "no industrial school can turn out a finished journeyman, but it can furnish the material out of which a finished journeyman can be made." This is an important and pertinent statement, which applies with special force to the agricultural college. Their attempt to turn out finished farmers has led them into error in planning their courses, affected their educational ideals, and brought upon them criticism as severe as did their early failure to accomplish that end.

It has been an unreasonable and unwise expectation that the agricultural colleges would turn out finished farmers, equipped at the same time with an education such as the world expects of a college man. The attempt to meet this popular expectation has impoverished their courses in elements which develop the many-sided man, and tended to make them simply training schools for technicians. This does not meet the present idea of education, technical or otherwise. As one speaker put it, "intensive knowledge of one subject does not compensate for extensive ignorance of everything else. A man's intellectual and social well-being must not be wholly subordinated to his vocational skill."

This broader conception of agricultural education was voiced by the President in the statement that these colleges "seek to provide for the people on the farms an equipment so broad and thorough as to fit them for the highest requirements of our citizenship, so that they can establish and maintain country homes of the best type and create and sustain a country civilization more than equal to that of the city. . . . The education to be obtained in these colleges should create as intimate relationship as possible between the theory of learning and the facts of actual life. . . . The ordinary graduate of our colleges should be and must be primarily a man and not a scholar."

And again he said: "We shall never get the right idea of education until we definitely understand that a man may be well trained in book learning and yet, in the proper sense of the word and in all practical purposes, be utterly uneducated; while a man of comparatively little book learning may nevertheless in essentials have a good education."

President Wheeler voiced this sentiment forcefully in his statement that "education inheres not in what you put into a man or what you hang onto a man, nor yet in sterilizing him or shaving him down to a standard shape; but in giving him, such as he is and such as his life activities may be, the opportunity in and through those activities of living his life fully and effectively and abundantly. Such education will therefore address itself perforce to the real doings and exercises of real life, and its definition will be: The guided practice of life, to the end that men may live."

Opposition to the college graduate in agriculture has very largely disappeared. He finds a ready market for the special qualifications which his education has given him. It is now recognized that if the college is not turning out finished farmers in the strictly practical sense, its courses are furnishing the material out of which finished farmers of superior type are made; that agricultural education must be intellectual and must deal with facts and principles rather

than with things alone. Such education not only rescues men from the rule of thumb, but equips them to use knowledge in a more discriminating way, trains them as men, and prepares them for leadership in the community.

The latter is a most important qualification, for, as the President said, "No farmer's life should lie merely within the boundary of his farm." Under present conditions the problem of the farm is much more than the growing of wheat and corn and cattle. To quote again from the President: "The problem of production has not ceased to be fundamental, but it is no longer final; just as learning to read and write and cipher are fundamental, but are no longer the final ends of education. We hope ultimately to double the average yield of wheat and corn per acre; it will be a great achievement; but it is even more important to double the desirability, comfort, and standing of the farmer's life. . . . We must try to raise the average of farm life, and we must also try to develop it so that it shall offer exceptional chances for exceptional men."

The agricultural college, with its experiment station and other agencies, is looked to as the leader in the movement for the improvement not only of agriculture as an industry, but the farmer as well and the social conditions of his environment. From it must come the men and the impulse and the plans for the "redirection of rural institutions," a subject ably discussed in Dean Bailey's presidential address upon *The State and the Farmer*.

Such broad conceptions of the field and mission of the land-grant colleges make them seem more truly educational and bring them closer yet to the problems of real life. They give us something toward which to work and a field which is most inspiring. They stand in strong contrast to the tendency to eliminate all lines of study which do not bear a direct and intimate relation to the production of wealth from the soil. They point to the fact that "the only way to uplift any industry is to develop among those who are engaged in it not only technical knowledge and skill, but intellectual and moral force."

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

Nitrogen availabilities by modifications of the alkaline permanganate method, S. M. HERRICK (*Virginia Sta. Rpt.*, 1906, pp. 27-30).—Tests of the official alkaline permanganate method and various modifications of it on sodium nitrate, dried blood, horn meal, hoof meal, bone meal, tankage, cotton-seed meal, raw leather, and peat are reported, from which it is concluded that the following modification of the method gives most satisfactory results: "Weigh out an amount of the sample containing 0.045 gm. of nitrogen and transfer to a 1,500 cc. thick-walled distilling flask. After connecting with a condenser to which a receiver containing a standard acid has been attached, digest with a mixture of 400 cc. of ammonia-free water and 100 cc. of alkaline permanganate solution (16 gm. of potassium permanganate and 150 gm. of sodium hydrate dissolved in water and made to the bulk of one liter) till 150 cc. is distilled."

The determination of phosphoric acid in form of ammonium phosphomolybdate, H. PELLET (*Bul. Assoc. Chim. Sucri. et Distill.*, 24 (1906), pp. 525-528; *abs. in Chem. Zentbl.*, 1907, I, No. 7, p. 595).—The author refers to the investigations of Graftian on this subject as confirming the results of previous work by himself, and explains the details of his method.

Phosphotungstic acid as a reagent for potassium, G. C. MEYER (*Chem. Ztg.*, 31 (1907), No. 13, pp. 158, 159).—Experiments are reported to show that phosphotungstic acid possesses much the same properties as a reagent for potassium as phosphomolybdic acid. Using a 20 per cent solution of sodium phosphotungstate about as accurate results were obtained, especially with high percentage solutions of potash salts, as with the platinum chlorid. The method is asserted to be cheap and convenient and especially adapted to industrial work.

On the determination of the calcium carbonate content of marls, M. J. VAN'T KRULS (*Chem. Weekbl.*, 4 (1907), pp. 29-32; *abs. in Chem. Zentbl.*, 1907, I, No. 19, pp. 756, 757).—The author reports that good results can be obtained by the use of acetic acid to set the carbon dioxide free if the fresh soil is first ground with successive small portions of water.

Recommendations as to the nomenclature of the proteins (*Proc. Chem. Soc. London*, 23 (1907), No. 321, pp. 53-67).—A joint committee of the Physiological Society and the London Chemical Society has recommended a classification of the nitrogenous constituents of animal and vegetable products. "The word protein is recommended as the general name of the whole group of substances under consideration." "The word proteid, which is used in different senses in this country and in Germany, should be abolished. . . . If used at all, the term albuminoid should be regarded as a synonym of protein."

Protein is divided into protamins, such as salmin and sturin; histones, like those separated from blood corpuscles; albumins, such as egg albumin and

serum albumin; globulins, such as serum globulin and fibrinogen; sclero-proteins, such as gelatin, keratin, etc.; phospho-proteins, such as vitellin, caseinogen, and casein; conjugated proteins, and derivatives of proteins.

Conjugated proteins are substances in which the protein molecule is united to a prosthetic group, the principal subdivisions being nucleo-proteins, gluco-proteins (mucin), and chromo-proteins (hemoglobin). The derivatives of protein include meta-proteins (acid-albumin, alkali-albumin), proteoses (albumose, globulose, gelatose, etc.), peptones, and polypeptids.

As regards peptones, "this term should be restricted to the further products of hydrolysis which differ from the proteoses inasmuch as they can not be salted out from solution and usually resemble them in giving the biuret test. It has been pointed out that certain vegetable products hitherto regarded as peptones do not give the biuret test. It does not appear possible to bring such exceptional substances into any general classification at present. The same difficulty in classifying arises in connection with certain other vegetable proteins—for instance, those which, like gliadin, are soluble in alcohol."

"The term caseinogen should be used for the principal protein in milk and casein for its derivative, which is the result of the action of rennet.

"The two principal proteins of the muscle plasma should be termed paramyosinogen and myosinogen; the term soluble myosin should take the place of von Fürth's soluble myogen-fibrin; the term myosin should be restricted to the final product formed during *rigor mortis*."

The chemistry of the protein bodies of the wheat kernel. II, Preparation of the proteins in quantity for hydrolysis, T. B. OSBORNE and I. F. HARRIS (*Amer. Jour. Physiol.*, 17 (1906), No. 3, pp. 223-230).—Continuing earlier work (E. S. R., 16, p. 846), the authors prepared in quantity specific proteids of wheat which they had isolated, namely, globulin, gliadin, and glutenin. The amounts of globulin obtained were not sufficient for extended study, and no attempt was made to prepare the proteoses for further investigation, "as we have no means of determining the origin of these proteoses or of separating the mixture into products of probable chemical individuality."

As shown by an average of 25 analyses wheat gliadin contained 52.72 per cent carbon, 6.86 per cent hydrogen, 17.66 per cent nitrogen, 1.14 per cent sulphur, and 21.62 per cent oxygen. Leucosin and glutenin had practically the same elementary composition as wheat gliadin, as did also the gliadin of rye. The authors believe, however, that glutenin and gliadin are distinct bodies.

The chemistry of the protein bodies of the wheat kernel. III, Hydrolysis of the wheat proteins, T. B. OSBORNE and S. H. CLAPP (*Amer. Jour. Physiol.*, 17 (1906), No. 3, pp. 231-265).—Studies of the cleavage products of the specific proteids of wheat are reported from which the authors conclude that gliadin, glutenin, and leucosin are separate and distinct bodies. Gliadin is free from glycozell, the 0.02 per cent found in one case being regarded as due to the presence of a trace of glutenin. Leucosin is similar in its composition to animal proteids, which perhaps has a bearing upon its occurrence in the wheat embryo in distinction to gliadin and glutenin, which are typical reserve proteids. Reference to earlier work is given above.

Studies on the true nature of gluco-proteins and leucins, L. HUGOUNEQ and A. MOREL (*Bul. Soc. Chim. France*, 4, ser., 1 (1907), No. 4, pp. 154-165).—Studies of the cleavage products showed that so-called leucins and gluco-proteins are mixtures of amido acids.

On the increase in weight in the hydrolysis of casein, J. H. LONG (*Jour. Amer. Chem. Soc.*, 29 (1907), No. 3, pp. 295-299).—The author investigated

the amount of water and hydrochloric acid absorbed by casein during artificial peptic digestion. The increase in weight was divided irregularly between the water and hydrochloric acid.

On the hydrolytic cleavage products of caseoplasteins, L. ROSENFELD (*Beitr. Chem. Physiol. u. Path.*, 9 (1907), No. 5-7, pp. 215-231).—So-called plasteins were prepared from casein by digesting the casein with pepsin and hydrochloric acid, neutralizing with sodium hydroxid, evaporating until the content of solids was about 30 per cent, acidifying with hydrochloric acid, and adding rennet, the resulting precipitate being designated plastein. The properties of 5 preparations of this kind were studied in comparison with casein. The plasteins showed a higher percentage of carbon and a lower percentage of nitrogen. The following cleavage products were obtained from the plasteins: Arginin, histidin, lysin, tyrosin, leucin, α -pyrrolidin carbonic acid, phenylalanin, and glutaminic acid. As compared with casein the plastein showed a much lower percentage of amids.

Disadvantages of potassium bichromate for the preservation of milk samples for analytical purposes, P. GRÉLOT (*Jour. Pharm. et Chim.*, 6, ser., 25 (1907), No. 8, pp. 369-373).—Various objections to the use of potassium bichromate are discussed. The most serious of these, according to the author, is the fact that potassium bichromate even in the proportion of 2:1,000 and without the addition of sulphuric acid produces in milk a substance giving the general reactions of aldehydes, which may easily lead to an error as regards the use of formaldehyde as a preservative.

The chemistry of Hehner's test for formaldehyde in milk, O. ROSENHEIM (*Analyst*, 32 (1907), No. 373, pp. 106-108).—Pure sulphuric acid and pure formaldehyde give no color reaction with proteins. A color is, however, obtained after the addition of small amounts of oxidizing substances. The author does not believe that this color is due to the interaction of the oxidation products of protein with formaldehyde. He obtained evidence, however, to show that the formaldehyde may first be oxidized, giving rise to an intermediate oxidation product which reacts with the protein, and also that the formaldehyde may first combine with the protein forming an aldehyde protein compound which subsequently becomes oxidized. The formaldehyde reaction, which is a general one for proteins, depends upon the presence of the tryptophane group in the protein molecule.

The cherry-red coloration of milk in the presence of concentrated alkalis, C. GAUTIER, A. MOREL, and O. MONOD (*Compt. Rend. Soc. Biol. [Paris]*, 62 (1907), No. 11, pp. 542, 543).—Tests are reported to show that the red color produced in milk by the addition of one-fifth its volume of 40 per cent potassium or sodium hydroxid is due solely to the simultaneous presence of a proteid and a carbohydrate, which is contrary to the view recently expressed by Krüger (*E. S. R.*, 18, p. 810). The reaction of glycocoll with lactose and maltose was so marked that the authors believe that glycocoll may be used for the detection of these two sugars.

A comparison and criticism of the methods for the detection and estimation of cocoanut oil in butter, T. R. HODGSON (*Chem. News*, 95 (1907), No. 2468, pp. 121, 122).—The author concludes that "the saponification number is of no practical value, either qualitatively or quantitatively. The Reichert-Wolny number may show some indication of the presence of cocoanut oil if the amount present in the sample is large. Wijsmann and Reijst's method [*E. S. R.*, 17, p. 834] is by far the best qualitative experiment, since it shows a difference between the 2 silver numbers in the presence of even as little as 5

per cent of cocoanut oil, but as a quantitative method it is of no value. Thorpe's method is an excellent confirmatory test, as is also the extraction of phytosterol. The only exact quantitative method is the iodine absorption."

Experiments on the determination of the molecular weight of oils and fats, W. NORMANN (*Chem. Ztg.*, 31 (1907), No. 17, pp. 211-214, *dgms.*, 8).—A method and apparatus for determining the molecular weight of oils and fats are described and analytical data reported.

The detection of cane sugar in milk and cream, W. H. ANDERSON (*Analyst*, 32 (1907), No. 372, pp. 87, 88).—The author finds that the Cayaux resorcin test is rapid and reliable. It consists in adding 0.1 gm. of resorcin and 1 cc. of strong hydrochloric acid to 15 cc. of milk and heating the mixture to the boiling point. In the presence of cane sugar a red color is produced.

Concerning starch, W. H. BLOEMENDAL (*Pharm. Weekbl.*, 43 (1906), pp. 1239-1265; *abs. in Chem. Zentbl.*, 1907, I, No. 3, pp. 176, 177).—The chemical composition and heat of combustion of potato starch, rice starch, wheat starch, and maranta starch are reported. According to the author, starches consist principally of β -amylose, the proportion of α -amylose varying from 8.3 to 17 per cent. Amylodextrin, as well as other hydrolysis products, is also present.

Polarimetric determination of sugar in honey, P. LEHMANN and H. STADLINGER (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 13 (1907), No. 7, pp. 379-419).—A critical study of analytical methods.

The influence of basic lead acetate on the rotation of sucrose in water solution, F. BATES and J. C. BLAKE (*Jour. Amer. Chem. Soc.*, 29 (1907), No. 3, pp. 286-293, *chart 1*).—The investigations reported show that the amount of basic lead acetate solution used in clarifying sugar solution for polarization affects the reading. This is attributed to the formation of soluble lead saccharates having specific rotations different from that of sugar. The reading was lowered by quantities of the lead solution less than 6 cc. and increased by larger amounts.

The use of polarized light in the detection, by means of a microscope, of rice and cornstarch in wheat flour, G. GASTINE (*Ann. Chim. Analyt.*, 12 (1907), No. 3, pp. 85-87).—According to the author, the microscopical methods outlined, which included the use of polarized light, gave very satisfactory results.

The detection of rice husks in bran, E. KINKELS (*Ann. Chim. Analyt.*, 12 (1907), No. 3, pp. 92, 93).—A note on the colorimetric identification of rice bran by means of dimethyl-*para*-phenylene-diamin.

A new method of determining hyposulphites in food in the presence of sulphites, A. GUTMANN (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 13 (1907), No. 5, pp. 261-265).—The method described depends upon the fact that potassium cyanid acted upon by thiosulphate forms potassium sulphocyanite, which gives a blood-red coloration of iron sulphocyanite on the addition of acidulated iron-chlorid solution.

Report on methods of beer analysis, H. E. BARNARD (*U. S. Dept. Agr., Bur. Chem. Circ.*, 33, pp. 16).—This is a full report of the associate referee on beer presented at the last convention of the Association of Official Agricultural Chemists (E. S. R., 18, p. 397). The methods which are given in this report and which are now before the association for adoption as official were based upon considerable cooperative work by 10 chemists.

The use of carbon bisulphid in the estimation of salicylic acid in wine, W. L. DUBOIS (*Jour. Amer. Chem. Soc.*, 29 (1907), No. 3, pp. 293, 294).—The dried ether extract from 100 cc. of wine is treated with ten 5 cc. portions of carbon bisulphid and the salicylic acid determined colorimetrically in this

solution. This method eliminates the tannin and coloring matters which interfere with the color reaction when ether alone is used as a solvent.

Mineral acids in vinegar, F. D. RATCLIFF (*Analyst*, 32 (1907), No. 372, pp. 82-84).—The author reports a comparison of methods for detecting mineral acids in vinegar and points out that results may be too high or too low, according to the method followed. In his judgment, commercial vinegar is no longer adulterated with mineral acids, so that the elaboration of methods for their detection is not necessary.

Progress made during 1906 in the examination of foods and condiments, Utz (*Österr. Chem. Ztg.*, 10 (1907), No. 6, pp. 72-79).—The data summarized have to do with the examination of water, milk, wine, fats and oils, flour, meat and meat goods, preservatives, condiments, etc.

Miscellaneous chemical analyses made in 1903, 1904, and 1905, A. M. PETER ET AL. (*Kentucky Sta. Rpts.* 1903, pp. 265-311; 1904, pp. 173-194; 1905, pp. 225-236).—These three reports contain analyses of 35 samples of sorghum, 48 of sugar beets, 15 of soil, 1 of marl, 5 of oats, 2 of horse weed (*Ambrosia trifida*), 1 of alfalfa, 1 of red clover, 3 of corn stover, 11 of commercial feeding stuffs, 19 of tobacco, 1 of distillery slop, 1 of corn, 8 of butter, 1 of wood ashes, 1 of sal Bordeaux, 3 of petroleum, 3 of forage plants, and 109 of mineral waters.

Examination of papers, F. P. VEITCH (*U. S. Dept. Agr., Bur. Chem. Circ.* 34, pp. 10).—This circular gives the "methods and tests by which the composition and value of paper are judged, examples illustrative of the nature and interpretation of results, and brief outlines of the characteristics which the more important classes of paper should possess."

METEOROLOGY—WATER.

Climate of Virginia, G. T. SURFACE (*Bul. Amer. Geogr. Soc.*, 39 (1907), No. 2, pp. 92-98).—Data for mean annual temperature, rainfall and snowfall, and length of growing season at 10 representative stations in Virginia from 1900 to 1905 are tabulated, and the climatic conditions of the different physical divisions of the State are discussed. It is shown that the climatic belts are in general coincident with the physical divisions of the State, namely, Tidewater, Middle Virginia, Piedmont, Blue Ridge, Valley, and Appalachia.

The mean annual temperature of Tidewater is 58 to 61° F., the rainfall 35 to 45 in., and the average growing season 7 to 7½ months. The mean annual temperature of the extreme southern Tidewater region is about 60°, and in this belt cotton is grown to a limited extent. The soil of the region is universally sandy or a sandy loam, which with adequate rainfall and a warm temperature is well adapted to truck farming.

The average mean annual temperature of the Middle and Piedmont regions is 56 to 58°. The growing season is 2 to 3 weeks shorter than in Tidewater. This region is especially adapted to tobacco culture.

The Blue Ridge, Valley, and Appalachia regions constitute the mountain district of the State. The mean annual temperature of Blue Ridge and the Valley is 52 to 56°, and of Appalachia 48 to 54°. The area covered by these regions is especially suited to grasses, grains, and apples. The length of the growing season is 5½ to 6 months in Blue Ridge and the Valley, and about 2 weeks less in Appalachia. This region, together with a part of Piedmont adjacent to Blue Ridge, is peculiarly adapted to apple culture.

The rainfall throughout the State is, as a rule, abundant and well distributed. "There is a wide variation in the snowfall of the State, both regionally and

seasonally. It is usually light and of short duration in Tidewater and Middle Virginia. From the Blue Ridge westward, however, it is not uncommon for the ground to be blanketed for a period of 6 weeks or 2 months. This is of great economic value to the grain and grass crops of the region, protecting them not only against the intense cold of January and February, but ameliorating the effect of the thaws of occasional warm days. . . .

"The climate of Virginia is ideally adapted to successful agriculture, since the prevailing conditions in the different geographic divisions are such as are best suited to the soils of those regions. . . .

"The rainfall has the most advantageous monthly distribution with reference to farming operations and the growth of crops, being somewhat heavier from April to July, which makes disastrous droughts unknown. The growing season of each section is always long enough to mature the standard crops of that section."

[**Meteorological observations, 1906**], H. L. PRICE (*Virginia Sta. Rpt. 1906*, pp. 36-38).—A monthly summary of observations on temperature, precipitation, wind movement, and cloudiness is given with a comparison of monthly temperatures and precipitation for 14 years.

Meteorological summaries for the years 1903, 1904, and 1905 (*Kentucky Sta. Rpts. 1903*, pp. 312-317; *1904*, pp. 195-198; *1905*, pp. 237-242).—Tabular summaries are given of observations at the station on pressure, temperature, precipitation, cloudiness, wind movement, and casual phenomena.

Meteorological observations (*Nature [London]*, 75 (1907), No. 1949, pp. 448-450, fig. 1).—This is a review of a number of articles which have recently appeared in meteorological journals on the following subjects: Sunshine and snowfall in 1906 in the British Isles, rainfall of Scotland in May, 1906, the atmosphere in the Tropics, meteorological observations on the summit of the Tsukubasan, Japan, meteorology of India, meteorological observations in Cape Colony, forty years of southern New Mexico climate (E. S. R., 18, p. 611), and meteorological observations in Germany by the Deutsche Seewarte, Hamburg, 1905.

Meteorological observations at Montpellier (*Ann. École Nat. Agr. Montpellier, n. ser.*, 6 (1907), No. 4, app.).—A diagrammatic record is given of observations at the observatory of the National School of Agriculture on temperature of the air and of the soil, pressure, humidity, rainfall, cloudiness, evaporation, and direction and force of the wind during June to November, 1906.

Distribution of rainfall during the year 1906, H. A. HUNT (*Agr. Gaz. N. S. Wales*, 18 (1907), No. 2, pp. 174-177).—The rainfall conditions of New South Wales during each month of the year are briefly described. The year as a whole was characterized by deficient rainfalls, 20 to 30 per cent below normal, for the coastal and mountain districts, and excessive rainfalls, 50 to nearly 100 per cent above normal, for other districts.

Experiments on hail shooting at Castelfranco, Venice, during the years 1902 to 1906 (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5, ser., 15 (1906), II, No. 2, pp. 680-682; *abs. in Ciel et Terre*, 27 (1907), No. 22, pp. 591, 592; *Science, n. ser.*, 25 (1907), No. 637, p. 434).—This is the report of a commission appointed by the Italian minister of agriculture to make experiments to determine the efficiency of the method of using explosives to dissipate hailstorms. Absolutely negative results were obtained during the five-year period of experiment, and the commission concludes that there is no hope of preventing damage by hail by means of so-called hail shooting, and that protection must be sought along wholly different lines.

After the freeze, P. J. WESTER (*Fla. Agr.*, 34 (1907), No. 4, p. 1).—The character and results of the Florida freeze of December 26, 1906, are briefly described and means of protection against such freezes are suggested.

The Müller self-registering anemometer (*Ann. Dir. Hydraul. et Amélior. Agr., Min. Agr. [France], 1906, No. 31, pp. 305, 306*).—The construction of this instrument is briefly described.

On the occurrence of nitro-bacteria in the sea, P. THOMSEN (*Ber. Deut. Bot. Gesell., 25 (1907), No. 1, pp. 16-22*).—Such organisms were found in the ooze from the Bay of Naples, the harbor of Kiel, and the roadstead of Helgoland, as well as in the surface waters.

On nitrogen-fixing bacteria from the Bay of Naples, W. BENECKE (*Ber. Deut. Bot. Gesell., 25 (1907), No. 1, pp. 1-7*).—The occurrences of Azotobacter vegetation was established contrary to the contention of Nathansohn.

Underground water supplies from a sanitary point of view, B. LATHAM (*Surveyor, 31 (1907), No. 792, pp. 382-384*).—This paper discusses the origin and quantity of underground waters, the sources of impurity, the effects of pumping, and the relation between typhoid fever and the water line, especially as affecting the water supply of London and other English cities.

[Municipal engineering in 1906 in relation to water supply and sewerage and sewage disposal] (*Surveyor, 31 (1907), No. 784, pp. 80-83, 85-91*).—These subjects are discussed in a general review of progress in municipal engineering during the year, particularly in Great Britain, but also in other countries.

SOILS—FERTILIZERS.

Report on statements of Dr. Cyril G. Hopkins relative to Bureau of Soils, W. M. HAYS and M. WHITNEY (*U. S. Dept. Agr., Office Sec. Circ. 22, pp. 12*).—This circular contains replies by the Assistant Secretary of Agriculture and the Chief of the Bureau of Soils of this Department to statements made by Prof. C. G. Hopkins, of the University of Illinois, in an open letter of March 26, 1906, and in an address as president of the Association of Official Agricultural Chemists, published as Circular 105 of the Illinois Experiment Station (*E. S. R., 18, p. 607*).

Transformation of volcanic rocks into aluminium phosphate under the influence of substances of physiological origin, A. LACROIX (*Compt. Rend. Acad. Sci. [Paris], 143 (1906), pp. 661-664; abs. in Jour. Soc. Chem. Indus., 25 (1906), No. 23, p. 1145*).—This article describes the large deposits of aluminium phosphate found on the Island of St. Thomas and on other islands in the Gulf of Guinea, which, it is asserted, are the result of the reaction of the excrement of sea fowl on the trachytes and other volcanic rocks of the island. Apparently such decomposition of siliceous rocks has not been before observed. The alkalis of the rocks have not been retained as phosphate, probably having been washed out by the copious rains to which the islands are subject.

A contribution to the study of the alkaline rocks of East Africa, H. ARSANDAUX (*Compt. Rend. Sci. Mission Duchesne-Fourquet [Paris], 1906, pp. 96, pls. 9; abs. in Amer. Jour. Si., 4, ser., 23 (1907), No. 135, pp. 230, 231*).—The author reports petrographical and chemical examinations of extrusive igneous rocks which cover large areas in French Somaliland in the southern part of the Afar region of East Africa. It is shown that "these rocks are of acid alkalic character and of three prominent types, rhyolites with agirite and riebeckite or comendites, pantellarites with agirite-augite and cossyrite and trachytes." The results are of interest as indicating the wide distribution in volcanic regions of highly alkalic rocks in which soda predominates.

On the formation of hardpan, T. MARR (*Meded. Proefstat. Oost-Java, 4, ser., 1907, No. 30, pp. 145-167*).—The formation and character of a peculiar hard layer known as "padas," which widely occurs in Java soils, are discussed.

Is there any considerable evaporation of ammonia from soils? LILIENTHAL (*Illus. Landw. Ztg.*, 26 (1906), No. 99, pp. 851, 852; *abs. in Chem. Ztg.*, 31 (1907), No. 9, *Repert.* No. 7, p. 42).—Summarizing the results of 6 years' experiments on soils rich in lime, the author finds that on such soils ammoniacal nitrogen not only gives as good results as nitrate nitrogen, but in some cases better results.

In recent experiments with barley on light sandy soils the efficiency of the ammoniacal nitrogen was from 97.6 to 98.5 per cent of that of the nitrate nitrogen. These results were obtained on soil which had been heavily limed. There was no evidence of any great loss of ammonia, certainly not greater than is due to drainage in case of nitrate of soda. It is important, however, to apply the ammonium sulphate some time (about 14 days) before planting and to thoroughly incorporate it with the soil.

Classification of forms of humus in forest soils according to the conclusions of the International Association of Forestry Experiment Stations, ALBERT (*Ztschr. Forst u. Jagdw.*, 39 (1907), No. 1, pp. 3-8).—The principal forms of nitrogen occurring in forest soils are classified and defined.

Industrial treatment of peat to increase its content of nitrogen in view of its application as a manure, E. V. H. BAZIN (*First Addition*, July 3, 1906, to French Patent 360,484, Dec. 14, 1905; *abs. in Jour. Soc. Chem. Indus.*, 25 (1906), No. 24, p. 1227).—A method of making and operating a niter bed made of blocks of peat and supplied with effluent from sewage septic tanks is described.

Soil inoculation (*Country Life* [London], 21 (1907), No. 527, pp. 182, 208, 209).—A brief account is given of experiments by A. W. Sutton with American and German cultures which gave unfavorable results, this being ascribed to the use of old or inferior cultures.

German nitragin and American nitro-cultures as inoculating material for leguminous plants, T. REMY (*Centbl. Bakt. [etc.]*, 2. Abt., 17 (1906), No. 19-21, pp. 660-673, figs. 9; *abs. in Chem. Ztg.*, 31 (1907), No. 11, *Repert.* No. 9, p. 53).—The author reports bacteriological tests of American nitro-cultures which as in previous years gave negative results as regards the characteristic tubercle bacteria. In comparative inoculation tests of this material with nitragin in water cultures, pot tests, and field experiments on various leguminous plants the nitragin gave good results while the nitro-culture produced no effect.

Atmospheric nitrogen (*Amer. Fert.*, 26 (1907), No. 1, pp. 5-7).—This article briefly discusses the relation of the world's supply of fixed nitrogen to the food supply, as well as the possibilities of adding to this supply by artificial methods of fixing the nitrogen of the air.

Fixation of atmospheric nitrogen, G. ERLWEIN (*Elektrotech. Ztschr.*, 28 (1907), Nos. 2, pp. 41-45, figs. 8; 3, pp. 62-66, figs. 13; *abs. in Electrochem. and Metallurg. Indus.*, 5 (1907), No. 3, pp. 77-79, figs. 4).—This paper describes in detail the theory and practical operation of the process of manufacturing calcium cyanamid, and discusses its uses and importance in the industries and in agriculture, summarizing the results of numerous comparative fertilizer tests of this material and of ammonium sulphate and sodium nitrate.

Future supplies of nitrogen for agriculture (*Cultura*, 19 (1907), No. 222, pp. 77-98, figs. 8).—Methods of preparing lime nitrogen and lime niter are described, and the agricultural value of these products is discussed. The importance of the acquisition of free nitrogen by leguminous plants is also considered.

The plants' supply of nitrogen, F. B. GUTHRIE (*Agr. Gaz. N. S. Wales*, 18 (1907), No. 1, pp. 40-55, figs. 17).—This article briefly discusses the formation

of nitrates in the soil, the assimilation of nitrogen by root-tubercle organisms, and the preparation and use as fertilizer of calcium cyanamid and lime niter.

The use of artificial nitrogenous fertilizers in agriculture (*Sucr. Indig. et Colon.*, 69 (1907), No. 6, pp. 154-158).—The results of various experiments in France with calcium cyanamid as compared with nitrate of soda are summarized, its behavior in the soil is described, and precautions to be observed in its use are explained. A caustic or toxic effect on germination and plant growth was observed when the cyanamid was applied at or near the time of planting. Serious losses occurred when the material came in contact with moist substances.

The Birkeland-Eyde calcium nitrate (lime niter) as a fertilizer, J. BÆRKNES (*Christiania: Norsk Hydro-Electrisk Kræftstofaktieselskab, 1906; abs. in Zentrbl. Agr. Chem.*, 36 (1907), No. 1, pp. 3-11).—The method of preparing this product is described, and pot and field tests of the fertilizing value of the material by various investigators are reviewed, the author's general conclusion drawn from the results being that lime niter is as effective as a source of nitrogen for plants as nitrate of soda and gives somewhat better general results on soils poor in lime.

Experiments with three new fertilizers. Experiments with cereals, E. COURRIÈRE (*Jour. Agr. [Paris]*, 41 (1906), 11, No. 2087, pp. 769-772; *Rev. Gén. Agron.*, n. ser., 1 (1906), No. 12, pp. 513-516).—This is a brief summary of the results of various experiments with nitrate of lime, nitrite of lime, and calcium cyanamid.

The influence of different carbohydrates and organic acids on the denitrification process, J. STOKLASA and E. VTEK (*Ztschr. Zuckerindus. Böhmen*, 31 (1906), No. 2, pp. 67-119; *abs. in Chem. Ztg.*, 30 (1906), No. 98, *Repert. No. 51*, p. 337; *Jour. Soc. Chem. Indus.*, 25 (1906), No. 23, p. 1162).—This is a report of an exhaustive investigation in which the influence of a large number of sugars and neutral salts of organic acids on (1) ammonization bacteria which reduce nitrates to nitrites and finally to ammonia, and on (2) denitrification bacteria which reduce nitrates to free nitrogen, was studied.

Of the first class, including among others *Clostridium gelatinosum*, *Proteus vulgaris* and *P. zenkeri*, *Bacillus ramosus* *n. liquefaciens*, *B. mycoides*, *B. megatherium*, *B. subtilis*, *B. prodigiosus*, etc., *B. mycoides* reduced 20.69 per cent of the nitrate nitrogen present to ammonia in the presence of glucose, 1.9 per cent in presence of fructose, 1.72 per cent in presence of galactose, and 1.91 per cent in presence of arabinose; *B. subtilis*, 2.41 per cent in presence of glucose, 6.55 per cent in presence of fructose, and 6.22 per cent in presence of galactose; *C. gelatinosum*, 45.55 per cent in presence of arabinose and 9.68 per cent in presence of xylose; and *B. prodigiosus*, 2.58 per cent in presence of xylose. The reaction was in all cases relatively slow and was not alike with all the sugars. For instance, *P. zenkeri* reduced 13.1 per cent of nitrogen in presence of glucose, but none in presence of fructose.

Of the second class, including *Bacterium hartlebi*, *B. fluorescens liquefaciens*, *B. pyocyaneum*, *B. stutzeri*, *B. flefaciens*, *B. nitrororum*, *B. centropunctatum*, *Bacillus denitrificans*, *B. coli communis*, *B. typhi abdominalis*, etc. *Bacterium hartlebi* set free 93.97 per cent of the nitrate nitrogen in presence of glucose, 87.59 per cent in presence of fructose, 74.66 per cent in presence of galactose, 66.38 per cent in presence of arabinose, 83.38 per cent in presence of xylose, 84.48 per cent in presence of cane sugar, and 77.15 per cent in the case of milk sugar; *B. centropunctatum*, 5.17 per cent in presence of glucose; *B. nitrororum*, 5.17 per cent in presence of fructose; *Bacillus coli communis*, 5.43 per cent in presence of galactose; and *Bacterium fluorescens liquefaciens*, 7.08 per cent in presence of arabinose. The reaction was as a rule very intense both with the sugars and with the salts of organic acids, especially of lactic acid, and was

accompanied by a gradual breaking up into carbon dioxide and hydrogen or into carbon dioxide and water, the hydrogen produced exerting a very important reducing action.

Chlorates are reduced to chlorids, arsenates to arsenites, and ferricyanids to ferrocyanids in the same manner as nitrates are reduced to nitrites, the reduction being a result of the oxygen requirement of the denitrifying organisms.

Xylan and araban, the most abundant and widely distributed carbohydrate materials in soils and manures, yield on hydrolysis xylose and arabinose, which are very poor sources of carbon and energy for denitrifying organisms. It was found, however, that the typical denitrifying organism, *B. hartlebi*, assimilated 33.6 per cent of the total nitrate nitrogen in a nutrient solution containing arabinose and converted it into albuminoid compounds. Since obviously soils do not contain the easily assimilable carbohydrates in any such proportions as they are found in nutrient solutions, the denitrification process will not be so intense in soils as is indicated by laboratory experiments. In fact, in the author's opinion, denitrification plays an entirely secondary rôle in the soil to nitrification and ammonization.

The action of fresh green manuring plants (mixture of peas, beans, and vetches) and beet tops in comparison with nitrate of soda, W. SCHNEIDWIND, D. MEYER, and H. FRESE (*Landw. Jahrb.*, 35 (1906), No. 6, pp. 923-926).—The fertilizing value of nitrogen in a green manure mixture (peas, beans, and vetches), in beet leaves, and in nitrate of soda was compared on oats followed by mustard in pot experiments with two different soils.

Taking the effect of the nitrate of soda in increasing the yield as 100, the effect of the other forms of nitrogen were green manure 39.3 and beet leaves 36.5. The relative utilization of the nitrogen by the oat crop and the following mustard crop was as follows: Nitrate of soda 100, green manure 52.5, and beet leaves 43.

Fish fertilizers, A. CLIGNY (*Ann. Sci. Agron.*, 3. ser., 1 (1906), 1, No. 2, pp. 166-187).—This article summarizes information on this subject from a variety of sources, giving statistics of the industry in France and other countries, and discussing the fish fertilizers under two heads, fertilizers poor in phosphates, especially those made in America from the menhaden, and fertilizers rich in phosphates, especially those made in Norway.

Can the lactic-acid bacteria exert a preservative influence on barnyard manure? C. BARTHEL (*Deut. Landw. Presse*, 33 (1906), Nos. 25, pp. 212, 213; 34, p. 292; *abs. in Centbl. Bakl. [etc.]*, 2. Abt., 17 (1906), No. 17-18, p. 567).—The author reports experiments which show that by adding milk or other lactose-containing substances to manure a vigorous lactic-acid fermentation is set up, with consequent fixing and prevention of loss of ammonia.

A manure platform, M. RINGELMANN (*Jour. Agr. Prat.*, n. ser., 13 (1907), No. 1, pp. 12-15, figs. 5).—Different kinds of manure platforms, with or without shelter, sprinkling devices, etc., in use in France are described.

Report on the operations of the Brunswick sewage farm during 1895 to 1900, H. BECKURTS and R. BLASIUS (*Ztschr. Hyg. u. Infektionskrankh.*, 55 (1906), No. 2, pp. 232-294, map 1).—Numerous analyses of the sewage water used, of the drainage water flowing away from the fields, and of the water of springs in the vicinity of the fields are reported, and the cultural management and financial returns of the farm are discussed.

The results show in general that the method of sewage irrigation was in this case an efficient method of purification without offense or injury to health of people living near the fields. The effluents from the fields were not found in any case to pollute springs of neighboring towns or of the Oker River, into which they were discharged. The agricultural products from the fields, especially the vegetables, were of good quality. The yield of grains was somewhat below the

average, but that of leguminous crops, grasses, and hoed crops in general was above the average. The total cost of the purification of the sewage of Brunswick by this method was about 23 cents per year and per capita of population:

Land treatment of sewage, H. T. SCOBLE (*Surveyor*, 30 (1906), Nos. 770, pp. 448-452; 771, pp. 476-480; 772, pp. 500-503; 773, pp. 528-531; 774, pp. 556-559; 775, pp. 580-584; 776, pp. 608-611; 777, pp. 632-635; 778, pp. 664-669; 779, pp. 696-701; 780, pp. 716-719).—A review of reports to the Royal Commission of England on this subject (E. S. R., 16, p. 1032).

Phosphoric acid experiments on different kinds of soils, W. SCHNEIDWIND, D. MEYER, and H. FRESE (*Landw. Jahrb.*, 35 (1906), No. 6, pp. 927-936, pt. 1).—The experiments here reported were made with 10 soils from different sources. The phosphoric-acid content of these soils and their behavior in pot experiments with oats when fertilized with phosphatic manures (superphosphate, Thomas slag, and bone meal) are shown in the following table:

Relation of phosphoric-acid content of soils to phosphate manuring.

Kind of soil.	Total phosphoric acid (dissolved by 10 per cent hydrochloric acid).	Phosphoric acid soluble in 2 per cent citric acid.	Phosphoric-acid content of the crop.		Response to phosphatic fertilizing.
			Grain.	Straw.	
	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>	
Heavy loess loam soil	0.81	0.45	0.86	0.16	No increase of yield.
Sandy soil16	.05	.92	.36	Do.
Do.05	.02	.57	.06	Do.
Clay soil16	.01	.57	.07	Small increase of yield.
Sandy loam soil09	.01	.19	.06	Do.
Sandy moor soil07	.01	.63	.06	Decided increase of yield.
Loamy sandy soil05	.01	.63	.09	Do.
Loess loam soil08	.02	.45	.05	Do.
Heavy loess loam soil15	.02	.47	.06	Do.
Do.08	.02	.63	.11	Do.

The results obtained indicate a certain relation in some cases between the phosphoric-acid content of the soil and the need of phosphatic fertilizers. In general, sandy soils poor in lime, magnesia, iron, alumina, and total phosphoric acid, but containing appreciable amounts of citric-acid-soluble phosphoric acid, did not respond to applications of phosphates. On the other hand, heavy soils rich in lime, magnesia, iron, and alumina were benefited by applications of phosphates even when containing much larger amounts of citric-acid-soluble phosphoric acid than the sandy soils. In other words, heavy soils rich in the constituents named must contain much more citric-acid-soluble phosphoric acid than sandy soils of the kind described before phosphatic fertilizers cease to be effective in increasing the yield.

Thomas slag gave as good results as superphosphate on light sandy soils, and bone meal was also very effective on such soils. In the heavy soils the Thomas slag was only 47 per cent as effective as superphosphate and bone meal was practically without effect. The efficiency of the latter apparently depends upon the reaction of the soil.

A rather definite relation between the phosphoric-acid content of the crop and the soil requirements was shown in these experiments, the soils producing plants low in phosphoric acid, as a rule, responding to applications of phosphatic fertilizers and vice versa.

Fertilizer experiments with different sources of phosphoric acid, H. J. PATTERSON (*Maryland Sta. Bul.* 114, pp. 113-144).—The experiments here recorded are a continuation of those reported in Bulletin 68 of the station

(E. S. R., 12, p. 930). They consisted of a comparison, on moderately stiff clay soil naturally quite well drained, of double superphosphates (both soluble and reverted), dissolved boneblack, dissolved South Carolina rock, iron and aluminum phosphate, boneblack, raw bone meal, phosphatic slag, ground South Carolina rock, and ground Florida soft phosphate, these materials furnishing all forms of phosphoric acid found in fertilizers and including all of the phosphates generally found in the market at the time the experiment was begun.

The average results on 6 crops of corn, 2 of wheat, and 3 of hay show that "(1) the highest total average yield was obtained with reverted phosphates; (2) reverted phosphate or iron and alumina [phosphate] produced a higher yield than reverted phosphate of lime; (3) insoluble phosphates produced a slightly higher total average yield than soluble phosphates and at about one-half the cost; (4) slag phosphate produced better results than bone meal and at less cost; (5) soluble phosphates produced the best yields of wheat; (6) Florida soft phosphate produced the best yield of corn; (7) reverted phosphates produced the best yield of hay; (8) insoluble South Carolina phosphate rock produced a higher total average yield than dissolved South Carolina rock; (9) insoluble South Carolina phosphate rock produced a little higher yield than boneblack; (10) bone meal produced a better yield of wheat than any other source of insoluble phosphate, but all other sources produced better grass."

General information on phosphates is given in an appendix to the bulletin.

The decomposition of dicalcium phosphate by water, K. BUCH (*Ztschr. Anorgan. Chem.*, 52 (1907), No. 3, pp. 325-341, fig. 1).—This is substantially a continuation of Rindell's work on the same subject first published in 1899.

A series of experiments is reported which show that under the action of water dicalcium phosphate is transformed into tricalcium phosphate. Whether this is the limit of the transformation or the latter continues until a basic compound is formed, the tricalcium phosphate being merely a comparatively stable intermediate product, was not determined, although there is evidence to indicate that this is the case.

On the intervention of micro-organisms in the utilization of insoluble phosphates of the soil by plants, S. DE GRAZIA and U. CERZA (*Arch. Farmacol. Sper. e Sci. Aff.*, 6 (1907), No. 1, pp. 6-17; *abs. in Chem. Centbl.*, 1907, I, No. 16, p. 1217).—Culture experiments with *Aspergillus niger*, *Penicillium glaucum*, and *P. brevicaulis* in media to which insoluble tricalcium phosphate was added are reported, showing that these organisms were quite active in rendering the phosphate soluble. The general conclusion drawn is that under ordinary field conditions a certain amount of insoluble phosphate is dissolved by the water which circulates in the soil and another considerable portion is dissolved by the action of micro-organisms, a part of the latter being used by the organisms in their growth and the remainder being immediately available for the use of the higher plants.

The action of the phosphoric acid of high and low percentage Thomas slag, W. SCHNEIDEWIND, D. MEYER, and H. FRESE (*Landw. Jahrb.*, 35 (1906), No. 6, pp. 937-940, pl. 1).—The results here reported of pot experiments with oats and rye on artificial soil (75 per cent sand and 25 per cent of humus loam) indicate that the phosphoric acid of high percentage and low percentage Thomas slag are about equally effective pound for pound. The experiments further show that the phosphoric acid of slags insoluble in citric acid is practically without effect in increasing the yield of crops. With oats superphosphate, precipitated phosphate, and Wolter's phosphate (prepared by fusing raw phosphate with lime and silicates) were about equally effective and much more effective than

Thomas slag. Steamed Thomas slag was less effective than ordinary, and tricalcium and Florida phosphates were almost without effect. The largest amount of phosphoric acid was assimilated by the plant in the case of the superphosphate, followed in order by the precipitated phosphate and Wolter's phosphate.

Treatment of double phosphates of iron and aluminium in order to render the combined phosphoric acid soluble in ammonium citrate, PILON ET AL. (*French Patent 368,521, July 30, 1906; abs. in Jour. Soc. Chem. Indus., 25 (1906), No. 24, p. 1227*).—A method of roasting such phosphates to increase their solubility in ammonium citrate is described.

Artificial fertilizers: Their nature and function, A. D. HALL (*Jour. Soc. Arts, 55 (1906), Nos. 2823, pp. 133-140; 2824, pp. 148-154; 2825, pp. 178-186; 2826, pp. 205-214; 2827, pp. 232-239, fig. 1*).—These articles constitute the Cantor lectures delivered before the Society of Arts in November, 1906, and discuss the general theory of the nutrition of plants, the sources and functions of nitrogen, phosphoric acid, and potash in fertilizers, and the importance of further investigation relating to the use of fertilizers. It is maintained that, while ordinary soils contain comparatively enormous quantities of nitrogen, phosphoric acid, and potash, they frequently do not contain these constituents in sufficient amount or available form for profitable crop production.

"A complete theory of manuring will always have two points of view, one special to the crop, the other to the soil; on good all-around soils, fertile loams and the like, the composition of the fertilizer employed will be dictated by the nature of the crop; on the more specialized soils, as on the pure sands, heavy clays or peats, it will depend primarily upon the soil."

In the discussion of the supply of nitrogen particular attention is given to recent progress in fixation of atmospheric nitrogen by micro-organisms in the soil and by electrical processes. It is pointed out that Great Britain is the most intensively farmed country in the world. It produces the largest crops per acre, but is obliged to spend the most to obtain them. This fact is made the basis of a plea for greater support for such investigations as are being carried on at Rothamsted relative to the increase of agricultural production.

The home mixing of fertilizers, F. BONSTEEL (*Farming, 3 (1907), No. 1, pp. 22, 23, figs. 2*).—The advantages and disadvantages of this practice are briefly set forth. The equipment required and the methods of selecting and combining the fertilizer ingredients are described, and the special fertilizer requirements of a few crops are explained.

Protecting the farmer against fraud, J. P. STREET (*Amer. Mo. Rev. of Reviews, 35 (1907), No. 205, pp. 213-216*).—The extent, methods, and advantages of inspection of fertilizers, feeding stuffs, and other agricultural materials in the United States are briefly reviewed.

To manure at a profit (*Mark Lane Express, 96 (1907), No. 3930, pp. 52-56*).—The sources of plant food available to the British farmer, the best means of determining the fertilizer requirements of the soil in a practical way, and the most profitable methods of using fertilizers are discussed.

Analyses of fertilizers, C. A. GOESSMANN (*Massachusetts Sta. Bul. 113, pp. 30*).—Analyses of commercial fertilizers collected in the course of regular inspection and of miscellaneous fertilizing materials sent to the station for examination are reported.

Report of analyses of samples of fertilizers collected by the commissioner of agriculture during 1906 (*New York State Sta. Bul. 285, pp. 81*).—"There are presented in this bulletin the analyses of samples of fertilizers collected by the commissioner of agriculture during 1906 and transmitted by him for

analysis to the director of the New York Agricultural Experiment Station, in accordance with the provisions " of the State fertilizer law.

Fertilizers, B. C. ASTON (*New Zeal. Dept. Agr. Ann. Rpt., 14* (1906), pp. 108-111).—Analyses of a number of typical fertilizers are reported, including, among others, ashes from timber mills, fish manures, fowl manure, whale refuse, bone ash, basic slags, sterilized bone meal, calcium cyanamid, and castor pomace.

[**Fertilizer market, New York, Chicago, Philadelphia, and Charleston**] (*Oil, Paint and Drug Reporter, 71* (1907), No. 6, pt. 2, pp. 47-49).—The fertilizer markets of these cities during 1906 are reviewed. It is stated that the year 1906 was " a most prosperous one to both the producers and manufacturers of the finished product." The larger use of fertilizers is ascribed principally to the raising of a big cotton crop, the South using during 1906, 500 lbs. of fertilizer to the acre, as against only 200 lbs. two years ago.

Circulars relating to the fertilizers and feeding-stuffs act, T. H. ELLIOTT (*Jour. Bd. Agr. [London], 13* (1907), No. 11, pp. 671-678).—Reprints are given of circulars issued by the Board of Agriculture and Fisheries of Great Britain, giving the rules and regulations adopted by the board for the administration of the fertilizers and feeding-stuffs act of 1906.

AGRICULTURAL BOTANY.

Annual review of botany, F. PÉCHOUTRE (*Rev. Gén. Sci., 18* (1907), No. 6, pp. 234-248, figs. 15).—A review is given of some of the more important contributions relating to chromosome reduction, parthenogenesis, sexuality in certain hybrids, experimental investigations on the origin of species, and sense organs in plants.

Botanical and agricultural studies in Java, W. DETMER (*Botanische und landwirtschaftliche Studien auf Java, Jena: Gustav Fischer, 1907, pp. 124, pl. 1*).—The author gives the results of his studies made in Buitenzorg during 1904 and 1905, the studies including vegetable physiology, forestry, and tropical agriculture. Following a general review of the agricultural practices in Java, chapters are devoted to comparisons between the plants and climates of Java and Central Europe; studies of Java soils; accounts of the cultivation of rice, tea, indigo, cacao, and cinchona; a description of the botanical garden at Buitenzorg; comparative studies between the primeval forests of Brazil and Java; investigations on the starch and sugar content of tropical and endemic plants; comparative studies of the transpiration of plants in Java and Jena; and a method of obtaining caoutchouc in Singapore.

The influence of climate on plant structures, C. HOLTERMANN (*Der Einfluss des Klimas auf den Bau der Pflanzengewebe, Berlin: W. Engelmann, 1907, pp. VIII + 249, pls. 16, figs. 7*).—The results are given of extensive anatomical and physiological studies made in the Tropics to determine the effect of tropical climatic conditions on the structure of plant tissues. Most of the investigations were made in Ceylon and confirmed in Java and elsewhere. Considerable attention is given to the transpiration of tropical plants, especially as influenced by the temperature and moisture relations. The different types of plant associations are described in considerable detail, after which chapters are devoted to the subjects of leaf fall and zonal, or the so-called year-ring, growth in the Tropics. A number of other interesting phenomena of plant growth in the Tropics are described, and the work concludes with a considerable list of publications relating to the investigations.

Variation in the sexuality of plants, D. Bois (*Rev. Hort.* [Paris], 79 (1907), No. 7, p. 153).—Attention is called to the variations reported in sexuality of flowers of species of willow and *Pistacia terebinthus*.

In the case of the willow it is claimed that the flowers were more or less regularly hermaphroditic with a varying preponderance of male or female flowers, depending upon the water supply of the plants. Submergence of willows by the overflowing of rivers was found to markedly affect the character of the flowers. When submerged deeply and for a long time, most of the flowers noticed were male, while on plants of the same species that were only temporarily inundated female flowers predominated.

The observations on *Pistacia* were made of cuttings from the same plant, one growing in a dry situation, while the other was irrigated. The irrigated plant bore male, female, and hermaphroditic flowers in the same clusters, while the one in dry soil bore only unisexual flowers. The following year the water in the irrigation canal failed and the inflorescences of the plant growing on its banks contained only unisexual flowers.

The growth of plants and the absorption of mineral substances, R. CHODAT, A. MONNIER, and DÉLÉANO (*Bul. Herb. Boissier*, 2, ser., 7 (1907), No. 4, pp. 350–352).—The authors state that the growth of plants and each of the principal mineral substances taken up by them may be represented by a curve up to the maximum, after which there is not only less assimilation but a return to the soil of mineral substances actually takes place.

A series of experiments was carried on not only to demonstrate the law of absorption of mineral substances, but also to test the value of different nitrogenous materials for the growth of oats. The oats were seeded in plats on April 12 and received identical treatment, except as to the form of nitrogen. The forms of nitrogen given were nitrate of soda, nitrite of soda, sulphate of ammonia, and calcium cyanamid. One hundred plants were taken from each plat and analyzed at intervals of about a week from the beginning to the end of growth, a period of 74 days elapsing between the first and last analyses.

There was a constant acceleration in growth and absorption of mineral substances up to the forty-third day, when the plants were in full flower. From that date until the fiftieth day the increase took place more slowly, and after 50 days, when the grain was fully formed, there was a diminution not only in assimilation but also in the total dry weight, the ash, and all the mineral substances contained in the ash.

In the second part of the experiment it was found that nitrate of soda gave the highest yields not only of grain but also of straw, followed by sulphate of ammonia, calcium cyanamid, and nitrite of soda.

On the application of the theory of limiting factors to measurements and observations of growth in Ceylon, A. M. SMITH (*Ann. Roy. Bot. Gard. Peradeniya*, 3 (1906), No. 2, pp. 303–375, pls. 1).—Investigations were conducted with a number of tropical species of plants to test the theory of Blackman, which is essentially as follows: As a rule, a single one of the physical factors limiting the physiological processes of plants determines the rapidity of the process, and when the rapidity of the physiological process is determined by a number of factors the slowest acting will limit the rate of growth.

The author has studied temperature, water supply, light, atmospheric pressure, wind velocity, etc., as factors limiting growth, and he divides his results according to whether or not the plants experimented upon possessed a reserve supply of food material. It was found that for plants having an abundant reserve food supply the three factors that limit the physiological processes are

light, temperature, and water supply. Of these light is often the least important and in many cases is wholly negligible. The other two factors may limit growth equally throughout the growing period, or they may in turn become the limiting factor according as their intensities vary.

In these investigations the temperature considered was that of the growing organ itself and not that of the surrounding air. The water-supply factor was found to be very complex and to depend upon absorption and transpiration, which in turn depend upon soil temperature, the water content of the soil, humidity of the atmosphere, and intensity of light.

In cases of growth without reserve food supply the previous conditions pertain, but in addition there must be favorable conditions for assimilation and transportation. It is believed that the irregular conditions of growth in the laboratory can be accounted for by the supposition that several different factors upon which growth depends became limiting in turn for shorter or longer periods. In the case of plants under open-air conditions, when all the external factors are liable to variation, it is even more probable that the irregularities of growth curves can be explained in this way.

Inclosing single plants and its effect on a large number of important agricultural species, C. FRUWIRTH (*Amer. Breeders' Assoc. Proc.*, 2 (1906), pp. 197, 198).—The object of the experiments which are briefly outlined was to ascertain the effect on seed production of inclosing the entire plant so as to prevent pollen from any other plant reaching it either by means of the wind or insects. The inclosing was done in a number of ways—oiled paper, linen bags, gauze, etc., being used for this purpose.

It was found that the following plants inclosed in this manner produced ample crops of seeds: Wheat, barley, oats, peas, several species of beans, vetches, camelina, opium poppies, beets, and tobacco. The following gave a greatly reduced quantity of seed: Rye, maize, *Vicia faba*, hairy vetch, a number of species of Brassica, crimson clover, carrots, timothy, meadow fescue, and meadow foxtail. No fruit or seed was produced from chicory, alfalfa, red clover, white clover, alsike clover, sulla, etc. In the case of sunflowers abundant fruits were produced, but the seed was sterile.

Correlation of characters in plant breeding, H. J. WEBBER (*Amer. Breeders' Assoc. Proc.*, 2 (1906), pp. 73-83, pl. 1).—After defining correlations, the author groups them into environmental, morphological, physiological, and coherital correlations. This latter group, which is the most interesting from a scientific standpoint as well as from that of practical value, is defined to include those characters which while not related to each other in any direct or casual sense are inherited as a single unit character. A number of correlations of this kind are pointed out in corn, peas, sugar beets, cotton, and other plants. A knowledge of these correlations is very valuable to the breeder, as it will enable judgment to be passed on the probable character of the product while the plants are still young or in their flowering stage.

The formation and distribution of essential oils in a perennial plant, E. CHARABOT and G. LALOUE (*Bul. Soc. Chim. France*, 4, ser., 1-2 (1907), No. 6, pp. 280-290).—The authors report a study made upon the absinthe (*Artemisia absinthium*) to determine the formation and distribution of the essential oil of that plant.

Studies were made of plants in all stages of growth, from seedlings to mature individuals, and it was found that the formation of essential oil took place most abundantly just previous to the period of flowering. Following this period there was a diminution in the essential oil, that material apparently being used in completing the ripening of the seed. In the roots of the young plants

no essential oil was present, and the stems contained relatively little, while it was abundant in the leaves. Later, after the period of flowering, it appeared in the roots, where its relative proportion was considerably increased with the age of the plant.

Vicianin, a new cyanogenetic glucosid occurring in the seed of vetches, G. BERTRAND (*Bul. Soc. Chim. France*, 4. ser., 1-2 (1907), No. 3, pp. 151-154).—An account is given of the isolation of a new glucosid, vicianin, which yields hydrocyanic acid under the action of a ferment. The glucosid occurs in the seed of *Vicia angustifolia*. The sample analyzed contained 0.75 gm. of hydrocyanic acid per kilogram of seed.

The detection of formaldehyde in plants, G. POLLACCI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 16 (1907), No. 3, pp. 199-205).—The author describes various methods for the determination of the occurrence of formaldehyde in plants and discusses its formation and function.

The relation of extractive to protein phosphorus in *Aspergillus niger*, W. KOCH and H. S. REED (*Jour. Biol. Chem.*, 3 (1907), No. 1, pp. 39-52).—The authors report a series of experiments with *A. niger* to demonstrate a change in the relative proportion of protein phosphorus to extractive phosphorus. This mold was selected as it is known to grow relatively well with small amounts of phosphates, while higher plants would be stunted in their development. The growth was made on the usual culture media to which various percentages of phosphorus in different forms were added.

It was found that nuclein phosphorus is the most important form of phosphorus at the disposal of the cell. It is produced at the expense of other forms, except lecithin, and is not decreased even in extreme starvation. Lecithin phosphorus is next in order of importance, but it is thought that it probably takes no part in the building up of the nucleins. The extractive or water-soluble forms of phosphorus are believed to be the ones from which the others are built up, and they represent the intermediary steps between the phosphates and the more complex combinations of phosphoric acid.

Investigations on the respiration of flowers, A. MARGE (*Rev. Gén. Bot.*, 19 (1907), No. 217, pp. 8-28).—The author reports experiments on a considerable number of flowers to determine their respiration in relation to the stage of their development. In the experiments individual flowers were tested in some cases, while in others clusters of flowers were taken.

It was found that for most plants the intensity of respiration of the flowers decreased regularly from the youngest stages of the bud to the full opening of the flower. The rapidity of this decrease varied with the different species, and all sorts of intermediate forms were observed between maximum respiration in the small flowering buds and the maximum in the case of the open flowers. In a small number of species the intensity of respiration was found to increase with the stage of development of the flower, attaining a maximum upon the expansion of the flower. The respiration of individual flowers nearly always showed an increase from the younger stages to the opening of the flower. For most of the species investigated the dry weight was found to decrease in a similar manner with the development of the flowers, and the rapidity of this decrease varied with the different species under observation.

FIELD CROPS.

Results of cooperative tests of varieties of corn, wheat, oats, soy beans, and cowpeas, A. T. WIANCKO (*Indiana Sta. Bul.*, 117, pp. 367-394, map 1).—This bulletin contains a summary of the results of tests with leading varieties

of corn, oats, winter wheat, soy beans, and cowpeas conducted by farmers in 1906, when sets of seed of varieties of these crops were sent to nearly 600 applicants, representing 88 of the 92 counties in the State.

The number of tests of varieties of corn was 453, of which 409 consisted of 5 varieties each, selected by the station according to the adaptability to the sections where they were to be tested. For this purpose the State was divided into 12 sections, 1 and 2 constituting the extreme northern portion of the State and 11 and 12 the extreme southern portion. The object was simply to compare the 5 varieties under the same condition without any special effort to secure large yields. The average yields and the order of ripening in sections 1 and 2 were as follows: Early Yellow Dent 60.8, Cook Yellow Dent 59.9, Dunn Yellow Dent 60.3, Cook White Dent 60.1, and Funk 90 Day 64.9 bu. per acre. Early Yellow Dent ripened about 10 days earlier than Funk 90 Day. In section 3 the order of ripening and average yields were Early Yellow Dent 44.5, Funk 90 Day 47.5, Leaming 53.5, Reid Yellow Dent 55.5, and Silver Mine 50.4 bu. per acre. The difference in ripening between Early Yellow Dent and Silver Mine was about 2 weeks. In section 4 all the varieties ripened at about the same time, with the exception of Early Yellow Dent, which was a few days earlier than the rest. The average yields secured were as follows: Reid Yellow Dent 62.4, Leaming 60.8, Silver Mine 58.5, Golden Eagle 55.7, and Early Yellow Dent 54.7 bu. per acre. In section 5 Reid Yellow Dent matured first, being followed in the order mentioned by Riley Favorite, Pride of the Prairie, Leaming, and Boone County White, the difference between the first and the last named variety being about 2 weeks. Boone County White gave an average yield of 56.3, Reid Yellow Dent 55.8, Leaming 53.2, Riley Favorite 52.3, and Pride of the Prairie 50.4 bu. per acre. In section 6 Boone County White ripened on the average about 8 days later than the other varieties. The average yields were as follows: Boone County White 75.5, Leaming 70.4, Reid Yellow Dent 70, Golden Dent 68.6, and Riley Favorite 67.3 bu. per acre. In section 7 the order of ripening, beginning with the earliest variety, was Reid Yellow Dent, Golden Dent, Leaming, Pride of Indiana, and Boone County White, with the average yields 61.1, 57.2, 61.6, 66.6, and 65.6 bu. per acre, respectively. Reid Yellow Dent ripened about 2 weeks earlier than Boone County White. The order of maturity in section 8, with the average yields of the varieties, was as follows: Reid Yellow Dent 50.8, Golden Dent 47.3, Johnson County Yellow 48.9, Pride of Indiana 58, and Johnson County White 62.3 bu. per acre. Reid Yellow Dent and Golden Dent ripened practically at the same time. In section 9 Johnson County Yellow ripened first, followed in the order given by Gold Standard, Pride of Indiana, Vogler White Dent, and Johnson County White, the difference between the first and the last being about 10 days. The average yields of these varieties ranged from 62.1 bu. per acre for Pride of Indiana to 65.1 bu. for Johnson County White. In section 10 Reid Yellow Dent was about 12 days earlier than Johnson County White. In this section the range of average yields was from 57.4 bu. for Reid Yellow Dent to 67.2 bu. per acre for Johnson County White. Vogler White and Pride of Indiana both yielded 60.1 bu. per acre, while Gold Standard gave 63.4 bu. In section 11 the yellow varieties ripened about a week earlier than the white varieties, while in section 12 little difference was observed. In section 11 the average yields per acre ranged from 48.8 bu. for Gold Standard to 55.9 bu. for Johnson County White, and in section 12 from 53.2 bu. for Pride of Indiana to 56.2 bu. per acre for Johnson County White.

For the purpose of making variety tests with winter wheat the State was divided approximately into the northern, middle, and southern sections. In the northern section the average yield ranged per acre from 26.3 bu. for Mealy

to 30.4 bu. for Rudy. Two lots of varieties tested in the southern section varied in yield per acre from 27.3 to 32.1 bu. for the one and from 26.8 to 29.4 bu. for the other.

The 5 varieties of oats tested in the northern section gave average yields ranging from 31.1 to 47.8 bu. per acre, and in the southern section from 28.8 to 41.6 bu. per acre. Silver Mine, Great Dakota, and Czar of Russia were very similar in appearance and gave quite similar results. Swedish Select matured about the same time as Silver Mine, but had a much larger and plumper grain. Sixty Day and Early Champion matured about 10 days earlier than the other varieties, but gave considerably smaller yields.

Results with soy beans indicated that Ogema requires about 95 days to mature seed, 1to San and Early Brown about 115 days, No. 12399 about 130 days, and Medium Early Yellow approximately 150 days. In yield of seed per acre Early Brown ranked first, with 29.4 bu., and Ogema last, with 14.5 bu. for northern Indiana, Early Brown first, with 19.8 bu. and Ogema last, with 12.7 bu. for central Indiana, and Early Medium Yellow first, with 20.7 bu., and Early Brown last, with 13.4 bu. in southern Indiana.

The 8 satisfactory reports on tests with cowpeas showed that the varieties in order of maturity ranked as follows: Early Blackeye, Michigan Favorite, Whip-poorwill, Iron, and Clay. The range in yield of seed per acre was in northern Indiana from 17.1 bu. for Early Blackeye to 19.3 bu. for Michigan Favorite, and in southern Indiana from 5.3 bu. for Clay to 11.3 bu. for Early Blackeye.

Department of field experiments, P. O. VANATTER (*Virginia Sta. Rpt. 1906*, pp. 50-60, figs. 2).—The results of experiments carried on in 1906 are briefly reviewed.

Of the varieties of winter wheat tested Blue Ridge and Mediterranean stood at the head, with a yield of 28.52 and 26.44 bu. per acre, respectively. Iron Clad, Blue Straw Fultz, Fulcaster, and Mediterranean had the highest protein content, analyzing 17.20, 16.80, 16.73, and 16.72 per cent, respectively. Blue Ridge ranked thirty-second in protein content, with 14.60 per cent. Turkey Red has not given good results at the station.

Two years' experience seems to indicate that the best time to sow winter wheat is from about October 1 to October 7, but it is stated that in certain sections east of the Blue Ridge sowing may be done from 2 to 4 weeks later. The work in seed selection with winter wheat shows that there is not so much to be gained by growing the seed from select choice heads as has been claimed. In experiments here reported the general average of the results shows an increase of only 3.96 bu. per acre in favor of large grains. It is believed that the safest and surest way of increasing the yield of wheat is to select individual plants of unusual promise, and work along this line has been inaugurated.

Union winter barley proved to be the best stooler and to make the quickest growth early in the fall. The best time to sow this crop seems to be about September 15, if the land is in good condition. This season Virginia Grey winter oats gave a better yield than Culberson, which made 38 bu. per acre on a $\frac{1}{2}$ -acre plat after cowpeas plowed under. Varieties of winter rye have not varied much in yield, although Excelsior is considered the leading sort.

Leaming, Boone County White, and Coker Prolific corn have given good results on rich land. Better yields were secured from improved strains obtained by crossing pure-bred western corn with the best native varieties than from strains obtained by crossing the native sorts with the western varieties without using pure-bred strains.

Of different fertilizer applications made after cowpeas were plowed under 300 lbs. of Thomas slag per acre apparently increased the yield of corn per acre by 8.39 bu., 50 lbs. of potash per acre by 3.13 bu., 300 lbs. of floats per acre by

2.68 bu., and 300 lbs. of cotton-seed meal per acre by 1.79 bu. The largest increase, 31.93 bu. per acre, from different fertilizer applications for corn after winter wheat was secured from 300 lbs. per acre of cotton-seed meal.

The Japanese, Extra Early Black, Medium Green, and Ito San Yellow soy beans ripened September 1, 1, 15, and 30, and yielded 14.16 bu., 16.66 bu., 20.83 bu., and 22.50 bu. per acre, respectively. The Whippoorwill cowpea has given the best general results at the station. Five varieties of Canada field peas were all failures. Of 20 varieties of potatoes the 5 leading in yield were as follows: Burbank 230, Early Rose 227, Beauty of Hebron 224, Green Mountain 201, and Gold Coin 197 bu. per acre.

Field experiments in Staffordshire and Shropshire and at the Harper Adams Agricultural College, G. BALFOUR and J. C. RUSHTON (*Harper-Adams Agr. Col. Joint Rpt., 1906, pp. 43, pls. 2, dgm. 1*).—At the college the experiments in manuring meadow land, in progress since 1903, have shown that the use per acre of 10 tons of barnyard manure, together with an application of $1\frac{1}{2}$ cwt. of nitrate of soda, $2\frac{1}{2}$ cwt. of superphosphate, and $\frac{1}{2}$ cwt. of sulphate of potash, gave the heaviest crop of all combinations tested, but that the use per acre of $2\frac{1}{2}$ cwt. of superphosphate and $\frac{1}{2}$ cwt. of sulphate of potash was the most profitable practice. The barnyard manure remained perceptibly effective for about 4 years. Superphosphate gave the most marked results, either alone or in combination.

Of 8 varieties of English and American wheats, Borwick Grey Chaff, Square Head Master, and Manitoba No. 1 led in productiveness, with yields of 56, 49, and 48 bu. per acre, respectively. Club wheat stood first in value for milling purposes, but gave the lowest yield, only 22 bu. per acre. Borwick Grey Chaff was poorest in milling quality. Of 5 varieties of barley, Carter Prolific ranked first in yield, with 40 bu. per acre, and also stood first in malting quality. Waverly, the best yielding of 9 varieties of oats, produced 71 bu. per acre, being followed by Garton Abundance, Thousand Dollar, and Highlander, producing 69, 66, and 63 bu. per acre, respectively. Thousand Dollar, Highlander, and Garton Abundance produced good, short, plump grains. The grain of Waverly, Wide Awake, Mounted Police, and Beslar Giant is considered too long and thin.

Commercial fertilizers applied with barnyard manure largely increased the average yield of mangels for 3 years. The use of 4 cwt. per acre of salt and of 4 cwt. of kainit, or $\frac{3}{4}$ cwt. of sulphate of potash, had a very marked beneficial effect on the crop in 1906. Dickson and Robinson Perfection, Sutton Prizewinner Yellow Globe, and Leighton Intermediate led in yield with 48 tons 15 cwt., 41 tons 7 cwt., and 39 tons 8 cwt. per acre, respectively. The largest yields of 30 varieties of swedes were obtained from Drummond Imperial and Carter Invicta. Ground lime at the rate of 10 cwt. per acre was more effective in reducing finger-and-toe disease than basic slag at the rate of 5 cwt.

The results of experiments in Shropshire were in favor of planting potatoes in rows 27 in. apart, of the use of immature Scotch and Irish seed potatoes, and of the boxing or sprouting of seed potatoes in boxes before planting. The largest total yields for the last 3 years were produced by Conquering Hero, Snowdrop, and Leda. Continued propagation from cuttings indicated a loss of vigor. The most expensive fertilization was the use of 20 tons of barnyard manure, and the most economical the use of $1\frac{3}{4}$ cwt. of sulphate of ammonia, $4\frac{1}{2}$ cwt. of superphosphate, and $1\frac{1}{2}$ cwt. of sulphate of potash per acre. A complete application of commercial fertilizers with 15 tons of barnyard manure per acre gave this season a better yield of mangels than 7 cwt. of a special mixture applied under the same conditions.

The Staffordshire experiments showed that for fertilizing grass lands superphosphate is much more effective than bone meal or pure dissolved bone, and that

complete commercial fertilizers as a rule produced the best results. A ton of compressed yeast per acre in one test increased the crop of hay by 5 cwt. at a cost of 2s. per cwt., but in another experiment with mangels the yeast apparently caused a decrease in the crop. Home mixed fertilizers were found more effective and economical than special mixtures in growing potatoes, mangels, and turnips.

Report on culture tests for 1905-1906, A. DAMSEAUX (*Bul. Agr. [Brussels]*, 22 (1906), No. 7, pp. 943-952).—The best yields of rye were secured with an application of 150 kg. of sulphate of ammonia per hectare, and the best yields of oats from the use per hectare of 400 kg. of superphosphate of lime, 100 kg. of sulphate of potash, and 100 kg. of nitrate of soda. Ligowo oats, which is highly esteemed for the quality of its grain, has a tendency to shatter and to ripen together with wheat, interfering with the harvest. In comparing 200, 300, 400, and 500 kg. of superphosphate of lime per hectare as a fertilizer for oats, the best results were secured with the applications of 300 and 400 kg.

Hanna barley yielded 2,400 kg. of grain and 4,200 kg. of straw, Chevalier 2,450 kg. of grain and 4,200 kg. of straw, and Polders 3,400 kg. of grain and 5,150 kg. of straw per hectare.

The results of fertilizer experiments with sugar beets show that on soils containing residual quantities of plant food, especially potash, the use of salt is not injurious to the beets, the production of sugar, or the purity.

Commercial fertilizers harrowed in or covered by hand gave practically the same results in fodder beet culture. Kirsche Ideal fodder beet proved much superior to the Eekendorf variety.

Notes are also given on the culture of potatoes, ruta-bagas, and colza.

Field tests with fertilizers, P. WAGNER (*Deut. Landw. Presse*, 34 (1907), Nos. 24, pp. 195, 196; 25, pp. 208, 209; 27, p. 221).—The results of experiments conducted for 5 years on a sandy soil, poor in lime as well as in the three essential elements of plant food, show that the average annual profit where complete commercial fertilizer applications were made amounted to 123 marks per hectare. When phosphoric acid was omitted the profits were reduced by 84 marks, when potash was omitted by 96 marks, and when nitrogen was not applied by 63 marks. It is estimated that for every 100 marks expended for fertilizers an increase in yield valued at 223 marks was obtained.

It was further found that in order to produce a maximum yield of 30,000 kg. of potatoes, or 3,000 kg. of rye or oats per hectare, 45 kg. of phosphoric acid and 100 kg. of potash per hectare would have to be applied annually in a rotation of potatoes and two cereal crops, but if fodder beets were grown instead of potatoes 50 kg. of phosphoric acid and 125 kg. of potash per hectare would be required.

With reference to nitrogen the experiments showed that the use of 200 kg. of nitrate of soda per hectare gave the best general results.

A method of breeding a strain of alfalfa from a single individual, J. M. WESTGATE (*Amer. Breeders' Assoc. Proc.*, 2 (1906), pp. 65-67).—The method is described and results of certain experiments are briefly noted. From these experiments the author assumes as a working hypothesis that self-fertilization is not impossible but that the meager data on hand indicate cross-pollination to be the rule where different strains are allowed to grow side by side without preventing the visits of insects.

Judging the quality of barley, C. BLEISCH and P. REGENSBURGER (*Zentbl. Agr. Chem.*, 36 (1907), No. 1, pp. 33-35).—In a study of this subject it was found that in connection with an increase in protein the nitrogen-free extract of barley in the samples examined decreased from 78.5 to 71.8 per cent, and the malt extract from 78.7 to 75.6 per cent, but that the curves of these two

factors were not quite parallel. The authors believe that a determination of the extract content is more reliable as a means of judging the malting quality of barley than the protein determination. An increase in protein was further associated with a high percentage of hull. It was also found that the malt extract produced from the dry matter of the grain decreased as the protein content increased. This fact was observed in practice as well as in laboratory experiments. In the process of malting the loss of protein was greater in high protein than in low protein barley.

A test of the producing power of some Texas seed corn, R. L. BENNETT (*Texas Sta. Bul.* 92, pp. 8).—The purpose of the experiment was to determine the variation in productiveness of corn grown by different persons, and of ears grown by the same person. Ears from a large number of farmers were tested, using an ear to a row 500 feet long. A low rainfall during winter and spring reduced the yield from all the ears. The highest yielding ear produced 26½ bu. per acre, or 12 bu. more than the average yield for all the ears.

Notes on the growing and selecting of seed corn and selecting and storing seed ears are given.

Practical corn breeding on a large scale, J. D. FUNK (*Amer. Breeders' Assoc. Proc.*, 2 (1906), pp. 89-93).—This article describes fully each successive step of the corn breeding methods employed by leading corn breeders of Illinois.

Value of corn pollen from suckers v. from main stalks, C. P. HARTLEY (*Amer. Breeders' Assoc. Proc.*, 2 (1906), pp. 141-144).—The results of the experiment reported in this paper indicate that the various ears produced by a stalk are of equal value for seed, that the pollen from the tassel of a sucker is of equal value with the pollen of the stalk that produces the sucker, and that the tendency to form suckers is hereditary and can be controlled by breeding.

Cotton culture, P. BONAME (*Sta. Agron. Mauritius Bul.* 15, pp. 17-22).—The following results were secured in comparative tests of varieties:

Results of variety tests of cotton in Mauritius.

Variety.	Cotton of good quality.	Seed cotton per plant.	Lint.	Yield per arpent.

Cotton in Algeria, F. GODARD (*Bul. Off. Gourt. Gén. Algérie, 1907, Sup.* 7, pp. 63-85).—Cultural experiments carried on in the region of Philippeville in 1906 have shown that cotton can be profitably produced on nonirrigated lands in certain parts of Algeria. The 2 Egyptian varieties, Mit-Affi and Yanovitch, particularly the first, appear well adapted to the coastal plains of the country and also to certain soils in the region of Philippeville. Georgia long staple proved the least resistant to drought, and its culture is therefore recommended only on the rich plains near the sea. Mississippi proved to be early and hardy and is believed to be better adapted to the higher altitudes than the other varieties mentioned.

The author recommends planting the Egyptian varieties and Georgia long staple 80 cm. by 50 cm., and the Mississippi at somewhat smaller distances. These directions are applicable only to nonirrigated lands. It is pointed out that where irrigation is practicable the yields are largely increased.

Leguminous crops for green manuring, C. V. PIER (*U. S. Dept. Agr., Farmers' Bul.* 278, pp. 27, figs. 14).—This bulletin discusses the use of green manures, the principal leguminous crops used for this purpose, how these crops get nitrogen from the air, and in general their adaptation to soil improvement. Descriptions are given of 9 different crops largely grown as green manures.

The Colorado potato industry, E. R. BENNETT (*Colorado Sta. Bul.* 117, pp. 23, figs. 15).—This bulletin describes the potato industry of Colorado, which is largely confined to the Greeley, Carbondale, San Luis Valley, and Divide districts. In the Greeley and Carbondale districts the most popular variety is the Improved Peachblow, also known as the Red or White McClure. Other varieties largely grown there are the Pearl, White Beauty, Carman No. 1, and Challenge. Monroe County Prize, Rural New Yorker No. 2, Pearl, and Champion are commonly grown in the San Luis Valley district. The Divide district is the only place in the State of any extent where potatoes are grown without irrigation. A specialty is made here of seed potato growing, and as much of this seed is used in the Greeley district the same varieties are planted.

The methods of potato culture are described for each district and notes are given on diseases, insect pests, harvesting, marketing, seed selection, and the cost of growing.

Observations made on the amount of water used by the crop when grown on alfalfa land and old potato land are reported. On the old alfalfa land 13.76 in. of water was supplied by irrigation and 8.75 in. by rainfall, giving a total of 22.51 in. as the total water used on the crop. On the old potato land 4.41 in. less water was supplied by irrigation, which is attributed to the difference in the physical condition of the soil in the 2 fields. The crop on the potato land ripened earlier and gave a smaller yield than that grown on the alfalfa ground.

Report on trials of varieties of potatoes, 1906, D. A. GILCHRIST (*County Northumb., Ed. Com., Bul.* 9, pp. 83-90).—At Cockle Park, Satisfaction ranked first in average yield among varieties grown for 3 years, and Dalhousie Seedling gave the best results in a list of varieties tested for only 2 years. Among the varieties tested at Dumbar, Factor, Dalmeny Acme, and Dalmeny Argon gave the best yields. In an experiment with tubers from different districts and countries the seed from Ireland and from Scotland produced the best crops.

With regard to winter and spring planting, it is shown that the heaviest crops were secured by planting early in March at Newcastle and early in April at Cockle Park. When the potatoes were not planted until May the results were much less satisfactory than from winter planting.

Potatoes for seed purposes (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 7 (1907), No. 2, pp. 241, 242).—Notes are given on the size of seed potatoes and the cutting and sprouting of the same, together with a summary of results of experiments on the sprouting of late potatoes from 1903 to 1906, inclusive. These experiments were cooperative and the yearly average gain in yield, due to sprouting before planting, ranged from 1 ton 13 cwt. to 2 tons 13 cwt. per acre.

Experiments with varieties of sugar cane, J. P. D'ALBUQUERQUE and J. R. BOYELL (*Rpt. Agr. Work Barbados, Imp. Dept. Agr. West Indies, 1903-1905*, pt. 3, pp. 67).—The results of work with seedling and other varieties of canes, carried on at 2 central stations and 13 other estates situated in typical localities, are reported for the season 1903-1905.

On the 15 estates, 12 in the black soil and 3 in the red soil regions, B 1529 ranked first with 7,402 lbs. of sucrose per acre, with B 208 coming next with

6,744 lbs. White Transparent, the cane at present usually planted in the island, under the same conditions gave 5,799 lbs. per acre. In the ratoon crops of 6 black soil and 2 red soil estates, B 208 gave \$2.58 worth of sugar more than White Transparent and B 1529 \$14.08 less. B 376 has proved a promising cane, averaging as plant cane in the black soil districts \$3.93 per acre more than the White Transparent. As plant canes on 3 red soil estates, B 208 produced sugar valued at \$32.32, B 1529, \$23.71, and B 376, \$10.31 more than the White Transparent. As ratoons on 2 red soil estates White Transparent gave \$16.27 per acre more than B 208, \$2.85 more than B 376, and \$80.85 more than B 1529. The data given also show that the average results with B 147 are better than those with White Transparent. An outline of future work is given.

Improvement of sugar cane by selection and hybridization, F. A. STOCKDALE (*Amer. Breeders' Assoc. Proc.*, 2 (1906), pp. 148-155).—A description is given of this work as carried on under the direction of the Imperial Department of Agriculture for the West Indies.

The influence of direct sunlight and diffused daylight on the development of the sugar beet, S. STRAKOSCH (*Separate from Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 1906, No. 1, pp. 11, figs. 2).—It was found that the sugar beet will reach its normal development when grown in diffused light, provided this is sufficiently strong. Direct sunlight, however, increased the substance in the plant, the increase being greater in the root than in the leaves. Growth in diffused light increased the nonsugars and decreased the percentage of sugar. The decrease in sugar content was not so marked as the decrease in the substance in the plant.

Intercellular transpiration proved to be stronger in the normal leaves than in those grown exclusively in diffused light, which, however, seemed to have a stronger epidermal transpiration. As compared with the plants grown in the shade, the leaves produced in direct sunlight contained larger-size stomata, and a larger number on the upper than on the lower side of the leaf. The translocation of the assimilation products in the shade-grown leaves was not so rapid as in the other plants. An increase in light intensity diminished the monosaccharids in comparison with the disaccharids of the leaves. Dextrose was found to be the predominating monosaccharid in the beet leaf.

The author concludes that the experiments suggest that the sugar in the beet leaf is not to be regarded as an intermediate product, but as a completely elaborated reserve material, which moves as such into the body of the beet.

The consumption of plant food by seed beets and transplanted beets, K. ANDRĚLÍK, J. URBAN, and V. STANĚK (*Ztschr. Zuckerindus. Böhmen*, 31 (1907), No. 6, pp. 339-350).—This second report on the subject deals with the use of plant food by the seed beet, and the data presented show that for the production of 3,506 kg. of seed per hectare 162.4 kg. of potash, 140.5 kg. of nitrogen, and 49.4 kg. of phosphoric acid are required. The relation of the quantities of plant-food elements in the beet at the end of the growing period of the second year was as follows: Phosphoric acid 1, nitrogen 2.84, and potash 3.29.

Analysis of sugar beet seed, E. SCHREBAUX and L. BUSSARD (*Semaine Agr.* [Paris], 26 (1907), No. 1378, pp. 84, 85; *Prog. Agr. et Vit.* (Ed. l'Est), 28 (1907), No. 14, pp. 413-417).—Based on the results of their investigations, the authors recommend that in the commerce of sugar-beet seed the following requirements be regarded as standard: That after 14 days of testing, the number of bolls germinating must be at least 70 per cent for the seed weighing less than 18 gm. per 1,000 bolls, 75 per cent for those weighing 18 to 22 gm., and 80 per cent for those weighing more than 22 gm.; that after 5 days of testing at least 80 per cent of the bolls capable of germinating must have produced a germ, or, in

other words, that the seed weighing less than 18 gm. per 1,000 bolls must have produced at least 56 per cent of sprouted bolls, those weighing from 18 to 22 gm. 60 per cent, and those weighing more than 22 gm. 61 per cent; and that the practice of giving the relative figures of sprouts per 100 bolls and per kilogram of seed be discontinued.

Variation in wheat hybrids, A. KEYSER (*Amer. Breeders' Assoc. Proc.*, 2 (1906), pp. 84-89).—The observations made during two years of work with over 200 distinct crosses obtained from 11 different varieties and including 16 type crosses, are discussed.

A brief description of the varieties and their chief characteristics is given. With reference to the transmission of the bearded character it was found that the first generation was intermediate—that the progeny of this intermediate form broke up into 3 forms, awnless, intermediate, and bearded, and that the intermediate forms so obtained again broke up into 3 forms and more or less closely in conformity to the following ratio: Awnless, 25 per cent; bearded, 25 per cent; intermediate, 50 per cent. The author states that according to Mendelian nomenclature the intermediate form may be considered as a true hybrid.

Methods in wheat breeding, A. KEYSER (*Amer. Breeders' Assoc. Proc.*, 2 (1906), pp. 186-191).—In a discussion of the subject the author states that in a study of all the progeny of a few mother plants to 3 generations it was found that the original mother plants showed wide variation in yield and composition, some producing a progeny varying widely, but averaging low in excellence; that some excellent mother plants produced uniformly very poor progeny, while others gave rise to uniformly good progeny; and that special qualities will be accurately represented in a composite from the best heads of the 5 or 10 best plants strong in the desired qualities. A method of wheat breeding taking cognizance of these facts has been evolved and is here described. The plan of the method is based upon straight selection without intervening hybridizations or crosses.

Breeding drought-resisting crops, R. GAUSS (*Amer. Breeders' Assoc. Proc.*, 2 (1906), pp. 108-112).—The desirability of securing drought-resisting crops for regions of low rainfall and the possibility of obtaining them by breeding is noted, and the results of experiments begun in 1896 with wheat are reported.

Improved Fife wheat was used in this work. Sowing seed broadcast did not give satisfactory results, so the method of planting single grains at intervals of 12 in. each way was adopted. Although the results secured from wheat planted at the rate of one plant per square foot is not considered a measure of what might be obtained by thicker planting, the author believes that the best results with a wheat of a small grain are obtained when sown not thicker than a half bushel to the acre.

The yield secured from different varieties of wheat, barley, and rye in 1905 is given and it is shown that the wheat from grains selected from plants showing drought-resistance was much greater than from the other wheat varieties. With only one plant to the square foot the yield was at the rate of about 13 bu. per acre.

The author's theory of selection is based upon the presumption that plants which in growth and maturity show the greatest drought-resistance will transmit that constitutional difference to their offspring. The results of this work indicate that a variety of wheat acclimatized to arid conditions will be relatively light in weight and have small grains.

Second report on the influence of fertilizers on the yield of timothy hay, J. W. GILMORE and C. F. CLARK (*New York Cornell Sta. Bul.* 241, pp. 19, figs.

7).—The first report on this work, in which the experiments were described, has been previously noted (E. S. R., 17, p. 461).

In 1906 the fertilizer treatment was the same as in 1904 and 1905, with the exception that on one plat the quantity of nitrate of soda given was doubled and on another 640 lbs. of nitrate of soda was applied per acre instead of 160 lbs. of "niterlime."

Eight plats without fertilizer in 1906 gave an average yield of timothy hay of 3,365 lbs. per acre, 3 plats receiving only mineral fertilizers, 5,133 lbs., 7 plats receiving nitrate of soda with or without mineral fertilizers, 6,451 lbs., and 2 plats receiving nitrogen in stable manure, 5,885 lbs. The plat which received 20 tons of barnyard manure per acre in the fall of 1903, without a later application of any kind, yielded in 1906 7,420 lbs. per acre, as compared with 2,410 lbs. on the check plats. Six plats receiving a complete commercial fertilizer in varying amounts and proportions yielded at the rate of 7,057 lbs. per acre, while 4 unfertilized plats yielded at the rate of 3,192 lbs.

The relative influence of the different fertilizers is shown in the following table:

Results secured with different methods of fertilizer treatment.

Number of plats.	Fertilizer treatment.	Apparent increase in yield of hay per acre.		Average of 2 years.
		1905.	1906.	
		Lbs.	Lbs.	Lbs.
1	Nitrogen	1,216	1,723	1,470
1	Phosphorus	607	417	512
1	Potassium	954	1,224	1,089
1	Nitrogen and phosphorus	1,573	2,126	1,850
1	Nitrogen and potassium	1,900	2,470	2,185
1	Phosphorus and potassium	510	1,780	1,145
4	Nitrogen, phosphorus, and potassium	2,613	3,543	3,078
2	Manure, 10 and 20 tons	3,310	3,475	3,393

Some of the plats receiving a complete fertilizer received, however, larger amounts of the single elements than where only 1 or 2 elements were applied. If the plats on which the quantities of the elements remained the same are considered, the apparent increased yield with nitrogen, phosphorus, and potassium was 2,432 lbs.

The relation of nitrogen to phosphorus on the Dunkirk clay loam in the production of timothy hay seems to be important, for where in these experiments too large a proportion of acid phosphate to nitrogen was used there was an apparent depression in yield. An application of 640 lbs. of nitrate of soda per acre was too large for the soil and the climate. Aside from the use of stable manure the most satisfactory yield was obtained by applying per acre 320 lbs. of nitrate of soda, 320 lbs. of acid phosphate, and 80 lbs. of muriate of potash. The largest average yield was obtained by the use of stable manure. A single application at the rate of 20 tons per acre produced an apparent increase of 11.2 bu. of oats in 1904, 4,025 lbs. of hay in 1905, and 5,010 lbs. of hay per acre in 1906. When the application was at the rate of 10 tons, the apparent increase per acre was 5.3 bu. in the yield of oats in 1904, 2,595 lbs. of hay in 1905, and 1,937 lbs. of hay in 1906.

Descriptions and illustrations of the seed of the genus *Nicotiana* (*Sinossi descrittiva ed iconografia dei semi del genere Nicotiana*), A. SPLENDORE (*Portici: R. Istituto Sper. Tabacchi Scafati, 1 (1906), pp. 163*).—The first volume of this work contains the descriptions of the seeds of the different types

and varieties of tobacco, with reference to their form, color, structure, dimensions, and weight.

The inspection of seeds under the Kentucky pure-seed law, H. GARMAN and M. L. DIDLAKE (*Kentucky Sta. Bul.* 127, pp. 129-169).—The working of the Kentucky pure-seed law is discussed and amendments to the same are suggested. A report on the samples examined is given and the details concerning adulterated samples are enumerated. The weed seeds most common in the samples are listed. Of the samples examined 36 were found adulterated as follows: Red clover 2, or 0.91 per cent; blue grass 12, or 8 per cent; orchard grass 21, or 19.4 per cent, and timothy 1, or 0.45 per cent. The text of the law is also given.

Commercial seeds of brome grass and of English and Kentucky blue grasses: Adulterants and substitutes and their detection, H. F. ROBERTS and G. F. FREEMAN (*Kansas Sta. Bul.* 141, pp. 69-112, figs. 38).—The seed and the plants of cheat, brome, and English blue grass are compared and described with a view to pointing out their distinguishing characters. The 3 species of plants are easily differentiated, and the seeds of brome grass and cheat are also easily distinguishable, but the seeds of cheat and of English blue grass resemble each other somewhat closely. The seeds of cheat frequently appear as a substitute for English blue grass seed and very often as an adulterant of it.

It is stated that every year nearly 700,000 lbs. of Canadian blue grass seed are used, chiefly for the adulteration of Kentucky blue grass. The 2 species of plants are easily differentiated, but the seeds are not distinguishable by the ordinary observer, and the distinguishing characters hitherto given are considered unsatisfactory aids to identification. This bulletin presents the following as "an absolutely new, hitherto unnoticed, and practically infallible test for distinguishing the seeds of Canadian from those of Kentucky blue grass:

"A careful examination of the palet in the two species shows a marked difference in the form and arrangement of the teeth on the lateral veins that we find to be constant for all cases where examined. In *Poa pratensis* [Kentucky blue grass] the palet is armed with teeth set well apart, long-acuminate, standing at progressively greater distances apart as the apex of the palet is approached, and finally disappearing short of the apex . . .; or, in rare cases, the teeth are wholly lacking. In *Poa compressa* [Canadian blue grass] the marginal teeth are shorter, blunter, not long-acuminate, continuous, not widely separated, becoming gradually smaller and of an equilaterally triangular form as the apex is approached; densely crowded together, like the teeth of a saw, without intervening spaces, and continuing up to the very apex of the palet . . ."

Increase in yield by treatment of the seed with concentrated plant food solutions, SCHLEH (*Pfählings Landw. Ztg.*, 56 (1907), No. 2, pp. 33-55).—The different experiments show that this treatment has the same effect on germination as soaking in pure water, provided the solution is not injurious to the germinative ability of the seed. The increase in the yield of grain was in most cases no greater than that resulting from the treatment with pure water.

Seed soaked in a weak plant-food solution gave better yields than seed not treated, with the exception that seed treated with a one per cent solution of nitrate of soda was in most cases injuriously affected. Soaking beet seed in liquid manure reduced the development of the root, but produced a marked increase in the development of the leaf.

Coating the seed with a dense solution generally interfered with the process of germination. In some instances this method increased the yield of the

grain, while in others it caused a reduction. This treatment also seemed to favor the development of the stems and leaves, and thus showed a tendency to increase the yield of straw.

A method of eradicating Johnson grass, J. S. CATES and W. J. SPILLMAN (*U. S. Dept. Agr., Farmers' Bul. 279, pp. 16, figs. 8*).—The results of investigations on the eradication of Johnson grass are reported and discussed.

It appears that the best method is to turn the land into meadow or pasture, keeping the grass closely cropped, either by grazing or mowing, for 1 or more seasons. The grass should never be allowed to stand after blossoming. After the sod has remained undisturbed for a year shallow plowing, with subsequent cultivation, is recommended. Running an ordinary turning plow from 3 to 4 in. deep will generally turn up all the root stocks, and if the land is then planted to a cultivated crop and given good cultivation the Johnson grass may be eradicated. Any shoots missed by the cultivator should be removed by hand before heading out.

HORTICULTURE.

Report of the field horticulturist for 1906, O. B. WHIPPLE (*Colorado Sta. Bul. 118, pp. 16*).—A report of the field work for 1906.

Special attention has been paid to the treatment of fruit and orchard diseases and a study of orchard conditions in Mesa County, Colorado. The bulletin contains notes on the various diseases under observation and their treatment, as well as on copper-sulphate injury to fruit trees, the thinning of apples, grape growing, setting out young trees, and general orchard conditions.

Horticultural report, R. S. NORTHROP and J. T. ATKIN (*Utah Sta. Bul. 97, pp. 9-24, figs. 8*).—The southern Utah experiment farm, which was established in 1899, was organized as the Southern Utah Experiment Station early in 1905, and variety tests of grapes, orchard fruits, and nuts under way at that time have been continued. Experiments are also being conducted in grape pruning, training, and resistance of vines to phylloxera.

The soil at the station varies, the eastern half consisting of sandy loam, which grades to a heavy clay loam in the extreme western portion. This latter type of soil is said to contain more or less alkali, and some attention has been given to the selection of varieties of grapes for this kind of land. It has been found that while all of the grapes succeed better on the higher and lighter soils, the Cornichon, Purple Damascus, Golden Champion, and Thompson Seedless are the best yet tried on the heavy land. These varieties, together with Black Ferrara and Muscat of Alexandria, are also considered the most promising on the lighter land.

A list is given of the varieties planted in the spring of 1902 on the lower soil, with notes on those which have fruited, together with the names of the varieties which have been recently planted at the station, and illustrations of several varieties resistant to phylloxera.

While the study of the various phases of grape culture forms the chief subject of the station work, tests are being made of a large number of orchard fruits and nuts, of which a complete list is given, with notes on varieties which have fruited. Vegetable testing, the use of cover crops, and the evaporation of fruits are some of the problems to be taken up.

Report of the horticulturist, R. S. NORTHROP (*Utah Sta. Bul. 98, pp. 32-41*).—Thus far the horticultural work at the station appears to be of a preparatory nature. Some of the problems to be taken up include an experiment to be conducted for a number of years with reference to the duty of water as applied to orchard and small fruits, and the study of commercial varieties of apples.

The station nurseries contain a great number of varieties of orchard and small fruits, and a list is given of those to be planted in the spring of 1907. A study will also be made of root diseases, with particular reference to the liability of inoculation at the time of budding, grafting, etc., the possibility of disinfecting, and the likelihood of transmission to clean stock after planting by means of irrigation, cultivation, etc.

Phenology notes, 1906, CHARLOTTE M. KING (*Trans. Iowa Hort. Soc.*, 41 (1906), pp. 203-218).—Popular data are given showing the blooming period of a great number of plant species, including flowers and fruit, as observed at 9 different localities in Iowa during 1906. The dates as given for different sections are found to bear a relation between the blooming time and the northward advancement of the season, as well as to different altitudes and latitudes. Similar data for 1904 has been previously noted (E. S. R., 17, p. 41).

Cabbages for stock feeding, S. FRASER (*New York Cornell Sta. Bul.* 242, pp. 23-35, figs. 8).—Popular directions are given for the planting, cultivation, treatment of insect pests and fungus diseases, marketing, and storing of cabbages grown for stock feeding, together with suggestions as to the methods of feeding, storing of seed cabbage, and seed production.

Tabulated data are also included, showing the results of variety tests of cabbage for the past 3 seasons.

The book of vegetables, A. FRENCH (*New York and London: The Macmillan Co.*, 1907, pp. XXVI + 312, pls. 7, figs. 144).—This book consists of a planting table for the vegetable gardener, including all the well-known vegetables and garden herbs, together with many recent introductions from other countries. The vegetables are arranged in alphabetical order, and a summary is given of the uses and culture of each, together with the merits of newer varieties and brief directions as to suitable soils, planting distances and depths, thinning, the use of special fertilizers, etc.

This work is intended as a supplement to the more complete treatises on vegetable gardening.

Tomato investigations, T. H. WHITE and W. R. BALLARD (*Maryland Sta. Bul.* 113, pp. 89-112).—This bulletin contains a detailed report of tomato experiments conducted since 1897, together with notes for general information on the selection of soil, location, fertilizers, and cultural methods.

The results of spraying and training experiments and variety tests are presented in tabular form. As with previous work the present results indicate that spraying can be conducted profitably.

Increased yields obtained from plants grown on poles are attributed chiefly to the greater number of plants which can be grown per acre in comparison with the usual field culture.

Results from variety tests indicate that promising varieties of tomatoes quickly deteriorate when "roguing" and selection is not continued. Brief descriptions are given of varieties grown in 1906.

Experiences with the onion crop, H. PRICE (*Amer. Agr.*, 79 (1907), No. 15, p. 444).—The author, who is an onion grower of Hardin County, Ohio, describes his treatment of the onion crop from seed to harvest, and states that he has obtained the best results with a fertilizer containing 3 per cent ammonia, 25 per cent available phosphoric acid, and 1 to 2 per cent potash. White Southport and Red and Yellow Globe are considered as the best varieties for commercial purposes in that section.

Horticultural novelties, C. M. UZAL (*Rev. Facult. Agron. y Vet. La Plata*, 2, ser., 2 (1906), No. 4-6, pp. 336-342, figs. 4).—Descriptions with cultural notes and illustrations of the bardana or gobo (*Lappa major*, var. *Edulis* L.) of Japan and the catawisa onion (*Allium fistulosum*). The gobo is an edible

variety of the common burdock of this country, the root, which is the part eaten, being prepared similarly to salsify. The catawisa onion, also known as the Welsh onion, is grown for its leaves and small aerial bulbels, which are said to be of value for pickling.

Biennial Report of Missouri State Fruit Experiment Station (*Missouri Fruit Sta. Rpt. 1905-6, pp. 18, pls. 1*).—The work of the station during the past 2 years has consisted primarily in the development of the variety orchard, together with some work in plant breeding, spraying demonstrations, and cooperative work in relation to pruning, cultivating, and the general care of orchards.

The station now has the following cross-bred and pure-bred seedlings: 10,000 strawberries, 1,070 apples, and 200 peaches, together with seed resulting from the crosses of 1906, numbering about 2,500 apples and 1,500 peaches. Of the 1,000 strawberry crosses which fruited during the past season, 50 varieties have been selected for further trial. Tables are given of the cross-bred and pure-bred peach seedlings, showing the parentage, description of the fruit, date of fruiting, resistance to disease, etc.

As the result of spraying for codling moth as high as 92.3 per cent of sound fruit has been obtained from sprayed trees, as against 19.1 per cent of wormy apples on unsprayed trees.

A list is given of the varieties of grapes grown at the station, showing their relative profitableness, susceptibility to disease, and value for table use or wine, together with notes on their growth.

In connection with the cooperative orchard work 4 plates accompany the text, illustrating pruning and clearing work.

Etherizing white Roman hyacinths, J. TAUBENHAUS (*Cornell Countryman, 1* (1907), No. 8, pp. 254-257, figs. 3).—The studies were made in order to determine the influence of temperature upon the growth of etherized bulbs, and to determine whether bulbs after being etherized need a rest. The method of procedure, in substance, was as follows: The bulbs were etherized with sulphuric ether in a tight tin box, where they remained for 24 hours and were then planted in pots. The etherized bulbs were then divided into 4 groups, the bulbs of the first group being forced immediately, and the remaining bulbs being forced 2, 4, and 6 weeks, respectively, after etherization. Each of these groups was again subdivided, portions being forced in a hot house, a medium house, and a cold house. The first bulbs to bloom were the etherized bulbs which were forced 2 weeks after etherization in the medium house. In each group the etherized bulbs bloomed earlier than the check. The length of stem and quality of flowers differed between the etherized bulbs and the checks, the flowers being somewhat larger and the stems considerably taller and stronger in the case of the etherized bulbs.

As a result of these experiments the author comes to the following conclusions as far as the white Roman hyacinths are concerned: The etherizing of the bulbs appears to hasten the blooming period, to improve the quality of flowers and size of stems, and to increase the amount of flowers. The best method of procedure is to etherize the bulbs, then plant in pots and allow them to rest for 2 weeks, thus encouraging the formation of the roots. A medium temperature is considered best, as too much heat appears to hold the bulbs back for 3 or 4 days. Where earliness of bloom is not particularly desired, the bulbs may be etherized and rested for 2, 4, 6, or even 8 weeks at any temperature between 50 and 80° F., with good results.

Renewal of old orchards, F. H. BALLOU (*Ohio Sta. Bul. 180, pp. 89-110, figs. 17*).—This bulletin contains practical lessons in orchard renewal as conducted

at the Ohio Experiment Station, where a block of run-down apple orchard planted some 40 years ago was brought into profitable fruit production, in order to cover the interval from the time of planting young trees until they should come into full bearing. The various phases of the treatment are discussed and illustrated by several figures.

Based upon the treatment of this orchard, the author is of the opinion that old orchards can be renewed in such a way as to produce fine fruit for home and market while the young trees are growing and that the plan of renewal, which is a process of pruning down the trees, brings about conditions under which insects and fungi can be so easily and effectually combated and controlled as to reduce to a minimum the danger of their spread to younger plantations.

During the first season of renewal the topmost branches should be cut out, leaving all healthy side branches. The next season the horizontal branches may be pruned so as to promote a uniform, well-rounded, symmetrical head and top. Suggestions are given as to the method of pruning and dressing large wounds caused by severe pruning. Heading back should be followed up by discriminate thinning of the new shoots and by cutting back those selected for future fruit bearing.

Renewal of orchards may be profitably accompanied by the addition of stable manure, either worked in the soil or allowed to remain upon the surface mixed with straw as a mulch. Suggestions are also given for the renewal of orchards other than apple.

Prime causes of failure in orcharding, L. H. BAILEY (*West. N. Y. Hort. Soc. Proc.*, 1907, pp. 27-28).—The author groups the causes of failure in orcharding into 2 classes: Crop-practice failures, and administrative failures, which are discussed in detail.

Fruit and orchard investigations, J. C. BLAIR (*Illinois Sta. Circ.* 197, pp. 58).—A list of some 24 problems, which at present seem to demand careful study, is placed before those interested in the development of Illinois horticulture, together with a brief statement regarding reasons why increased appropriations are being asked for experimental work in horticulture.

The circular also includes a discussion of investigations accomplished as a result of State appropriations, consisting of fruit-storage experiments (*E. S. R.*, 14, pp. 356 and 1072), bitter-rot investigations, botanical investigations of horticultural interest, investigations on injury to apples by curculio (*E. S. R.*, 16, p. 1098), comparison of the relative merits of liquid and dust sprays for apples (*E. S. R.*, 17, p. 1093), spraying for second brood of codling moth, fertilizer and drainage experiments, a study of the yellow leaf and brown spotting of foliage of fruit trees, and demonstration work. Bulletins are to be prepared during the coming year giving the details of the several lines of investigation not already reported.

The banana, P. HUBERT (*Le Bananier. Paris: H. Dunod & E. Pinat, 1907*, pp. X + 222, figs. 46).—This is the second of a series of practical books on Colon, Colombia, which the editors propose to publish. In this work the banana is treated from an agricultural, industrial, and commercial standpoint.

Part 1 deals with the origin, botany, varieties, and climatic and geographical distribution, together with methods of planting, cultivation, and subsequent care of bananas both for fruit and fiber. A chapter is also devoted to estimates of cost and returns in the development of a banana plantation. Part 2 treats of the selection of bananas for exportation and home consumption, and the manufacture of starch, sugar, alcohol, wine, brandy, vinegar, and fiber, together with the use of bananas for animal feeding. Part 3 is devoted to a discussion of the economic and commercial importance of the banana in various countries.

Fruit list (*Trans. Iowa Hort. Soc.*, 41 (1906), pp. 220-225, charts 4).—A list is given of apples, crabapples, plums, cherries, grapes, and small fruits suggested as standard varieties for Iowa, together with a list of supplementary varieties. Varieties are indicated which appear to be specially adapted to the northern drift soil and to the southern loess soil. Charts are included showing the nature of the soil, elevation, rainfall, and temperature throughout the State, for the purpose of assisting those interested in the study of varieties.

Methods and results of hybridizing fruits, T. WILLIAMS (*American Breeders' Assoc. Proc.*, 2 (1906), pp. 184-186).—The author enumerates some of his results in hybridizing various stone fruits, apples, and a few pears. The origin of the Victor Sand Cherry, Red Glass, and Red Glass Junior plums is given, together with the crosses which were used to produce fruit of desired characteristics. He has been successful in reproducing the Talman and the Sickle pear and hardy types of peaches, as well as a hardy apricot, in eastern Nebraska. A new method of grafting was used, which is not clearly described, but which appears to be a modified adaptation to scion-grafting of the method employed in budding trees.

Breeding hardy raspberries for the Northwest, N. E. HANSEN (*American Breeders' Assoc. Proc.*, 2 (1906), pp. 128, 129).—The author points out the great need of hardy raspberries for the Northwest prairie region and reports the results secured from his efforts of the past 10 years at the South Dakota experiment station in securing hardy varieties. A large number of native raspberries were gathered from the Dakotas, Minnesota, Manitoba, and Assiniboia, together with varieties from three different continents.

Out of many thousands of seedlings which have been raised under high cultivation, several of those which have fruited have been selected as worthy of propagation. One variety, named the Sunbeam, has proven especially promising. It is a hybrid of Shaffer Colossal with a wild red raspberry from North Dakota and is said to be vigorous, productive, and capable of enduring severe winter conditions. The author states that the work is to be continued until varieties are secured which are not only hardy but adapted to a large area.

The strawberry test plot, F. H. BALLOU (*Ohio Sta. Bul.* 178, pp. 41-68, figs. 22).—Notes on 109 varieties of strawberries tested at the station during the season of 1906. The numerous varieties are described in detail and in a majority of cases illustrated. The results for each variety are tabulated, showing the sex of the flower, the dates of first blooming and ripening, periods of heaviest fruiting, largest single picking, date of last picking, and total yield in quarts for the season.

Grape breeding, S. A. BEACH (*American Breeders' Assoc. Proc.*, 2 (1906), pp. 191-197).—The historical development of commercial varieties of grapes and the grape industry in the eastern portion of the United States is outlined. The author states that in 1848 only two native grapes, viz, Isabella and Catawba, were placed on a selected list of fruits for general cultivation as adopted by the Congress of Fruit Growers assembled in New York. Since that time a large number of varieties have been developed in the eastern portion of the United States, but their parentage is, for the most part, either vague or entirely unknown. Reference is made to the work of several prominent grape hybridizers, and the origin of many well-known varieties is given.

For a better system of grape breeding more attention should be paid to the varieties which are now available for breeding, in order that the characteristics of the resulting crosses may be foretold with some degree of certainty. In his own work at the New York State experiment station, which has been carried on for over 14 years, the author has succeeded in making certain combinations

of parents which will always produce white-fruited seedlings and others in which red is the fixed color. In all, about 225 groups of grape seedlings have been bred in this way.

Length of life of vines of various species and varieties of grapes; profitableness; and by what diseases seriously affected, T. V. MUNSON (*Texas Sta. Bul.* 88, pp. 18, figs. 9).—The author presents data covering a period of 19 years, secured for the most part from his records of an 8-acre grape vineyard planted in 1886-7 near Denison, Texas. The soil in this vineyard is a light sandy soil from 6 in. to 3 ft. deep, with a red and yellow clay subsoil. The land has had but one application of fertilizer, consisting of a heavy coat of cotton-seed meal some 12 years ago. Data have also been collected from vineyards grown on different soils, including "black waxy" and lime soils.

In table 1 the relative longevity, health, and vigor of 26 species of grapes grown in the vineyard at Denison are noted. The species usually found native to lime soils are distinguished from those native to sandy soils. Table 2 gives the names of each variety cultivated, the specific blood, the number of vines of each planted in 1887, and the number and percentage alive in 1905, together with notes on the color, economic value and use of the fruits, and condition of the vines in 1905. The varieties are noted which have been found suitable for "black waxy" soils with clay subsoils, and for "black waxy" and "adobe" soils underlaid with white rock as near as 2 ft. from the surface.

The author presents data on extensive personal observations and reports secured from different experimenters in Texas on the adaptability of different varieties of grapes for the limy soils in Texas. It is stated that all species and varieties grow well in sandy soils where carbonate of lime does not exceed 25 per cent of the soil. Some species will flourish in soils which contain as high as 10 to 60 per cent of lime.

Varieties much subject to rot and mildew are not recommended for planting in the humid forest region of east Texas unless spraying with sulphate or carbonate of copper solution is thoroughly attended to. Grapes are not considered to succeed well in boggy or seepy soils on account of late frosts and fungus diseases.

The text is accompanied with plates illustrating several species of grapes.

Reestablishment of vineyards in Charente, France, J. M. GUILLOX (*Jour. Agr. Prat., n. ser., 13 (1907), No. 10, p. 307*).—Many of the vineyards of Charente, France, containing poorly adapted graft stocks are being reestablished. For the purpose of aiding this work the author here presents brief notes on the value of the principal stocks for grafting, resistance to phylloxera and to drought, adaptability to different percentages of lime in the soil, fruitfulness, etc.

The economics of viticulture, A. MARESCALCHI (*Coltivatore, 53 (1907), Nos. 8, pp. 229-231; 9, pp. 263-267; 10, pp. 295-298; 11, pp. 327-330; 12, pp. 367-370; 13, pp. 393-396; 14, pp. 426-428, figs. 10*).—In a series of short articles the author considers the economic side of the various phases of grape culture, including the equipment, preparation of the soil, various planting systems, cultural and spraying methods, systems of training, subsequent care, and cost of labor.

Male or seedless cocoanuts, A. W. BARTLETT and J. BELLING (*Agr. News [Barbados], 6 (1907), No. 128, p. 87, figs. 4*).—Notes are here given, together with illustrations, of seedless cocoanuts found in British Guiana. It is stated that these cocoanuts are sometimes found growing on trees with perfect fruit and at other times on trees which produce only seedless fruit. They may be distinguished from perfect fruit by their shape, the seedless fruit being much narrower.

Vanilla, F. L. TUERO (*Rev. Agr. [Santo Domingo], 3 (1907), No. 24, pp. 393-397*).—An account of the sorting, grading, and packing of vanilla, together with its chemical composition, uses, and adulteration, and estimates of the profits of a vanilla plantation.

The total cost per hectare of vanilla is estimated as \$469.35, and the gross returns in products as \$1,630, leaving a net return of \$1,160.65.

FORESTRY.

Farm forestry, E. J. ZAVITZ (*Ontario Dept. Agr. Bul. 155, pp. 40, figs. 27*).—This is a popular bulletin intended to aid the farmer in developing a rational treatment of wooded lands and in reforesting waste portions of the farm.

The subject is treated under 2 general headings, the woodlot and forest tree planting. Under the woodlot the injury from fires and stock grazing are discussed, and directions are given for making the woodlot a permanent and paying part of the farm. The portion devoted to forest tree planting deals with tree planting in relation to the farm and the small landowner, including a discussion of the choice of species with reference to their hardiness, rate of growth, nature of soil, kind of wood crop desired, and availability of planting material.

Directions are also given pertaining to nursery and planting methods, the planting of swamp lands, planting chumps for protection of stock, storm protection belts, and planting along permanent fences. Lists are given of 72 trees indigenous to Ontario, and of a large number of trees introduced from the United States and other countries.

The level of subsoil waters with regard to forest, R. S. PEARSON (*Indian Forester, 33 (1907), No. 2, pp. 57-68, pls. 3*).—In order to determine the effect of forest growth upon the level of subsoil waters as compared to cleared lands, during 1904 and 1905 the author took a series of readings both in and outside the Mohulia forest in India. An outline, together with tabular data, is given of these readings, as well as a description with charts of the results secured from similar experiments by M. Ototzky in Russia (*E. S. R., 16, p. 672*) and M. Tolsky in Russia and M. Henry in France (*E. S. R., 15, p. 125*).

Upon comparing the results of these experiments the author reaches the following conclusions: In all cases the water levels inside the forests are lower than those outside the tree influence during the same period. The water level is steadier and the effect of rain is felt later inside the forest than outside. It has been shown in Europe that the difference of the level is greater farther inside than on the edge of the forest, and that old woods lower the level more than young woods. In India the effect of a short rainfall in any given year takes more than one normal rainfall to compensate the former deficiency. The amount of rainfall in any locality has a marked influence on the difference of level in and outside of forests. Thus, in a low rainfall area the difference of levels is greater than where the rainfall is more abundant.

Report of forest administration in the Andamans for 1905-6, F. TRAFFORD (*Rpt. Forest Admin. Andamans, 1905-6, pp. 33*).—This is a report of the progress of the year 1905-6 in the State forests of the Andaman Islands, and includes a discussion of the constitution and management of State forests, the preparation of working plans, forest protection, sylviculture, exploitation, etc., together with a financial statement of the year's work. The important features of the work are presented in tabular form.

During the year 606,198 cu. ft. of timber were extracted by government agency, as compared with 493,601 cu. ft. last year. The surplus of revenue over and above the expenditure was 236,539 rupees, as compared with 247,843 rupees

last year. One of the principal features of the work was the exploration of the forest of the South Andamans, and the completion of a working plan for these areas by F. H. Todd.

The reforestation in the department of Aube, France, L. PARBÉ (*Rev. Eaux et Forêts*, 46 (1907), No. 7, pp. 193-207).—The author here presents notes submitted by M. Ména, conservator of forests and streams at Troyes, on private reforestations which have been carried out in the department of Aube during the last half century.

The department is divided into 6 regions according to the nature of the soil, and descriptions are given of the work of reforestation in each of these regions.

Native trees of the Transvaal, J. BURTT-DAVY (*Transvaal Agr. Jour.*, 5 (1907), No. 18, pp. 413-433).—The author has been engaged for some time in the publication of an illustrative and descriptive account of Transvaal trees. The present work is a preliminary classified catalogue of the species, with notes as to their distribution.

The native trees of the Transvaal are said to occur in well-marked phytogeographic zones of vegetation. These zones are indicated and alphabetical lists are given of the species occurring in each, together with a list of families arranged alphabetically under their main divisions and classes. The total number of trees classified consists of 57 families, which are subdivided into 132 genera and 269 species.

Soap trees, R. GUENTHER (*Daily Consular and Trade Rpts.* [U. S.], 1907, No. 2852, p. 4).—In a brief note reference is made to a large plantation of soap trees at L'Arba, near Algiers, from which several thousand tons of berries are said to be gathered annually. The tree is described as resembling an apple tree of medium growth. The fresh fruit is green and its pulp surrounds a kernel containing a yellowish, gelatinous, sticky substance which is said to contain three times as much soap as the "panama" wood. This soap is expected to be of great service to the cloth and linen manufacturers, as well as for domestic purposes, since it can be used to clean linen and silken fabrics and colored embroideries without causing the colors to run together.

Caoutchouc, E. LEVASSEUR (*Rev. Écon. Internat.*, 1 (1907), No. 3, pp. 607-624).—This is a discussion of the development of the rubber industry in various tropical countries of America, Asia, and Africa, including a description of the methods of exploitation, species grown, statistics for a period of several years as to the exportation of rubber from the principal rubber-producing countries, the importations to the principal rubber-consuming countries, and the value of different grades of rubber.

On the occurrence of calcium oxalate in the barks of the eucalypts, H. G. SMITH (*Jour. and Proc. Roy. Soc. N. S. Wales*, 39 (1905), pp. 23-32).—The barks of the Mallees, or dwarf species of eucalyptus of New South Wales, were examined to derive information with regard to their tanning value, as well as to make clear some of the problems connected with these dwarf species, which occur in large quantities in many parts of Australia.

From all the different species examined, calcium oxalate crystals were separated in varying quantities, ranging from 16.66 per cent in *Eucalyptus gracilis* to 0.08 per cent in *E. morrisii*. The general appearance and thickness of several barks tested are described. The species which contain crystals in the greatest abundance seem to be those which have a very thin, smooth bark, or at most a but slightly persistent bark at the base. It has already been determined that in those barks which contain much calcium oxalate the tannin is decidedly superior to that found in species in which the crystals are present only in small amounts.

Progress of wood preservation in 1906, C. G. CRAWFORD (*Forestry and Irrig.*, 13 (1907), No. 3, pp. 132-138, figs. 3).—In this paper, which was originally presented at the annual meeting of the Wood Preservers' Association, Memphis, Tenn., January, 1907, the author discusses the advancement made in the preservation of wood during the past few years.

Prior to 1901 there were about 15 timber-treating plants in the United States. At present, they number about 50, 5 having been erected in 1906 alone. The author states that consumers now realize that artificial preservation must be employed, not only because the renewal of certain species of wood is unusually expensive, but because such preservation greatly reduces the amount of structural timber required. The investment of large sums in extensive engineering enterprises is also creating a prudent regard to the future supply of timber.

The activity in wood preservation is said to have manifested itself along the following lines: An increase in the number and capacity of treating plants, improvement in the existing methods, the introduction of new methods from abroad, together with the development of methods peculiarly American and designed to meet American requirements, and a promoting of a more careful and detailed study of the technology of American woods, with an investigation of the constituents and properties of the preservatives in general use. The author discusses these various phases somewhat in detail.

Forest products of the United States, 1905, R. S. KELLOGG and H. M. HALE (*U. S. Dept. Agr., Forest Serv. Bul.* 74, pp. 69).—This bulletin contains detailed statements upon the lumber cut, cross-ties, tight cooperage stock, tan bark, and the wood used for mine timbers, pulp, veneer, and distillation in 1905.

The subject-matter has been previously published in a series of Forest Service circulars (E. S. R., 18, pp. 447, 448, 642, and 745).

The timber supply of the United States, R. S. KELLOGG (*Forestry and Irrig.*, 13 (1907), No. 4, pp. 187-193).—A large number of statistics upon the timber supply of the United States are brought together in convenient form for comparison and reference. These statistics are derived for the most part from census reports, bulletins of the Forest Service, and lumbermen's estimates.

Tables are given and discussed showing the lumber cut by States of the United States from 1880 to 1906, inclusive, the estimated stumpage of the United States from 1880 to 1905, and the estimated stumpage and cut of yellow pine in 7 southern States.

DISEASES OF PLANTS.

A text-book of fungi, G. MASSEE (*London: Duckworth & Co., 1906*, pp. XI+427, figs. 144).—The author's object in this book is to call attention to some of the more recent contributions on the morphology, biology, and physiology of fungi, and to indicate where further information on these lines of research may be obtained.

After a discussion of the anatomy of fungi, accounts are given of the formation of spores, methods of reproduction, effects of various physical and chemical agents on growth of fungi, parasitism, symbiosis, biological forms, geographical distribution, ecology, etc. A special chapter is given to the author's views on the phylogeny of fungi, and, after a description of the diseases due to fungi, their propagation, and legislation regarding plant diseases, a general scheme of classification is presented, which is a modified form of that of Brefeld.

Report of the plant pathologist, R. E. SMITH (*California Sta. Bul.* 184, pp. 219-258, figs. 12).—A review is given of the work carried on by the plant pathologist during 1906, the principal investigations having been made on pear blight, walnut blight, brown rot of lemons, beet blight, peach blight or shot-hole

fungus, tomato diseases, and asparagus rust. In addition, investigations have been begun on rose diseases and citrus fruit diseases.

The pear blight work is largely in cooperation with the Bureau of Plant Industry of this Department, and consists in the application of the methods recommended by that Bureau. A detailed account of the investigations in the different counties is given. It has been found that thorough winter pruning prevents blossom infection in the spring, and that the larger the district covered in the winter the less will be the infection the following season. Frequent and prompt summer cutting is to be practiced, and if not exposed to extremely abundant infection, a pear orchard can be profitably maintained in good condition.

The walnut blight investigation has been a continuation of studies on the bacterial disease of walnuts due to *Pseudomonas juglandis*. Thus far the disease has proved difficult to control, as spraying experiments have not been very successful. The size of the trees made spraying almost prohibitive, on account of the difficulty and expense.

The investigations on lemon rot, due to the fungus *Pythiacystis citrophthora*, have been previously described (E. S. R., 18, p. 344).

The beet blight described appears to be due to a derangement in the normal functions of the plant, and investigations seem to show that by attention to planting and cultivation in connection with weather conditions the disease may be largely controlled.

The peach blight or shot-hole fungus reported upon is due to a species of *Corynem*, and spraying with Bordeaux mixture proved quite efficient in controlling it. In addition to the peach, the almond is subject to this disease, and probably the fungus will be found to attack other stone fruits.

The tomato disease investigations are briefly summarized from a previous publication (E. S. R., 17, p. 1082).

The other investigations are briefly described, and the bulletin concludes with a list of the more common plant diseases that have been observed throughout the State, with notes as to their relative importance.

Report of the government mycologist, T. PETCH (*Circ. and Agr. Jour. Roy. Bot. Gard. Ceylon, 3 (1906), No. 21, pp. 277-286*).—Among the fungi observed during the year the author reports particularly upon leaf and root diseases of tea, Para rubber, cacao, Castilleja, and cotton.

The tea diseases attacking the leaves were gray blight (*Pestalozzia guenpinii*), brown blight (*Colletotrichum camellia*), and *Cercospora theae*. The root disease was principally due to the fungus *Rosellinia*. Stem diseases due to *Nectria* are also described.

The leaves of *Hevea brasiliensis* were found to be attacked by *P. guenpinii*, *Helminthosporium heveae*, *Gliosporium brunneum*, and *Colletotrichum heveae*. The root diseases described were caused by *Fomes semitostus*, *Poria rincla*, and an undescribed species of *Hymenochaete*. A blackening and decay of *Hevea* fruits, which was observed to be especially destructive, was due in most instances to a species of *Phytophthora*, similar to that found on cacao pods in other countries. In addition, the rotting fruits showed the presence of *Spharouma album*, *Nectria diversispora*, and *Diplodia zebrina*.

The species of *Hymenochaete* which occurs on *Hevea* was found attacking cacao as a root parasite in several instances and also destroying the roots of cotton.

The principal parasite observed on Castilleja was *Botryodiplodia clastica*, which attacked trees the bark of which had suffered injury.

Indiana plant diseases in 1906, F. D. KERN (*Indiana Sta. Bul. 119, pp. 427-436*).—Lists are given showing the distribution of various plant diseases

throughout the State in 1906, and reports obtained from cooperative correspondents form the basis for calculating the losses due to these causes. The diseases are listed under the headings of orchard fruits, small fruits, field, garden, and hothouse crops, and cereal and forage crops. Suggestions are given for their control, based upon cultural methods and the application of fungicides.

Peridermium acicolum the æcidial stage of **Coleosporium solidaginis**, G. P. CLINTON (*Abs. in Science, n. ser., 25 (1907), No. 63*), pp. 289, 290).—An abstract is given of a paper by the author in which it is stated that *Peridermium acicolum* was found to be abundant on *Pinus rigida* in Connecticut during the spring of 1906. From observations and infection experiments the author has determined that this fungus is the æcidial stage of *Coleosporium solidaginis*, which is common throughout the United States on golden rod and asters.

Ascigerous forms of Glæosporium and Colletotrichum, C. L. SHEAR and ANNA K. WOOD (*Abs. in Science, n. ser., 25 (1907), No. 63*), p. 291).—The authors report having studied forms of these fungi from the grape, apple, cranberry, rubber plant, honey locust, ginkgo, cotton, and beans. The ascigerous form on the apple had been grown before, but, so far as known, on none of the other species had these forms been produced. So far as could be determined there were no morphological characters which separated the different forms, and for the present they are to be regarded as varieties of a single species. The ascigerous form has been found under natural conditions in only two cases, on the apple and on the rubber plant.

The use of the seed plat in the prevention of diseases in wheat, E. M. FREEMAN (*Amer. Breeders' Assoc. Proc., 2 (1906), pp. 49-53*).—The author discusses smut and rusts as the most important of the diseases of wheat and calls attention to the fact that seed treatment is more or less efficient for the prevention of smut, but that for the prevention of rust the selection of resistant varieties must be relied upon.

In order to combat these diseases it is suggested that 3 plats of wheat be maintained, (1) the seed plat, (2) the increase plat, and (3) the general farm crop. In seeding the first plat the seed should be thoroughly treated for the prevention of smut, and before the time for harvesting all smutted plants should be destroyed. If persisted in for a time this will result in a crop wholly free from smut.

To secure freedom from rust it will be necessary to conduct a systematic and rigid selection of disease resistant individuals.

By following out the author's suggestions it is claimed that it will be possible to secure an improvement in yield, earliness, etc., the prevention of the spread of weed seeds, the prevention of loose smut and bunt, and improvement in rust resistance.

Anatomical physiological study on the influence of environment and excessive fertilization upon the diminished or lost resistance to brusone of bertone rice, R. FARNETI (*Riv. Patol. Veg., 2 (1906), Nos. 1, pp. 1-11; 2-3, pp. 17-42*).—It is claimed that in 1828 when bertone rice was introduced into Italy it was of lower growth than at present, with a slender more rigid stem, with smaller heads, and with more abundant root hairs. At first it was considered as being almost if not absolutely immune to brusone. During the past 70 years it has gradually lost its resisting power to this disease, the mechanical tissues have become reduced in relative proportion, and all the other tissues have become softer. A study of the effect of environment and the excessive use of fertilizers indicates that these agents have not greatly influenced the epidermis but have increased the cavity in the stems and therefore weakened the plant to a greater or less extent.

A detailed account is given of the differences in anatomical features of this variety of rice in so far as comparisons can be made between former conditions and those that prevail at the present time. It is believed that the loss of resistance to brusone is a phenomenon which accompanied the exaggerated variation in the plant in recent years and is due to the action of fertilizers rather than to climate and other features of environment.

A number of infection experiments were carried on with a commonly recognized species of *Piricularia* and *Helminthosporium*. The brown spots characteristic of infection from these fungi are described. The author concludes as a result of his study that *Piricularia grisea*, *P. oryza*, *Helminthosporium oryza*, and *H. turcicum* are different names of the same species for which the name *Piricularia oryza* is preferred.

In combating brusone sulphate of copper may be used at the rate of one-half part to 100 of water. Some browning of the leaves and glumes is produced, but where this treatment is adopted or Bordeaux mixture is used at the same rate as copper sulphate, the total weight of the crop is not appreciably diminished.

A bacterial disease of cherry trees, R. ADERHOLD and W. RÜHLAND (*Arb. K. Biol. Anst. Land u. Forstw.*, 5 (1907), No. 6, pp. 293-340, pl. 1, figs. 12).—In continuation of previous studies (*E. S. R.*, 17, p. 1165), the authors give further accounts of their investigations on a bacterial disease of cherry trees that has become quite destructive in parts of Germany.

Bacillus spongiosus, the organism suspected as being the cause of this disease, has been repeatedly isolated, and inoculation experiments show that there can be no doubt that it is actively parasitic. Other organisms, particularly various species of fungi, appear associated with this disease, but they are considered as of secondary importance.

After giving a technical description of *B. spongiosus*, the authors describe their inoculation experiments in considerable detail. In their experiments they frequently found other species of bacteria, one of which seems quite constant, but is believed to be saprophytic. This species seems to be undescribed, and the name *B. irritans* is given it.

In the previous account of this disease attention was called to a somewhat similar disease on apples and plums. Subsequent investigations of bacterial diseases of plum, prune, and apple trees showed that, while the organisms resemble those causing the cherry tree disease, the bacteria are not identical. Experiments comparing *B. spongiosus* with *B. amylovorus*, the cause of the pear blight, showed their nonidentity.

The authors state that the bacteria causing the cherry tree disease are undoubtedly conveyed from tree to tree by insects and possibly to some extent by winds and rain. In attempting to combat the disease all means possible should be adopted to prevent insect visits. All infected parts of the trees should be cut off and burned and the wounds disinfected.

The paper concludes with a description of the associated species, *B. irritans*, which is called a common saprophytic accompaniment of *B. spongiosus*.

A brief list of the literature relating to bacterial diseases of fruit trees is given.

Takeall in wheat (*Jour. Dept. Agr. So. Aust.*, 10 (1906), No. 5, pp. 280-283).—A description is given of a disease of wheat, due to *Ophiobolus graminis*, reported as being present in practically every wheat district of South Australia, and in some instances diminishing the yield fully 30 per cent.

There seems to be a difference in susceptibility of different varieties of wheat to this fungus. There is very little knowledge regarding preventive measures

to be taken, but the application of iron sulphate at the rate of 70 lbs. per acre, burning over infested areas, rotation with oats or other plants which do not seem to be subject to the disease, and allowing the land to lie fallow for a season or longer have been recommended. In view of the differences in susceptibility, the author thinks that there is more prospect of combating the trouble by the selection of resistant varieties.

In addition to wheat, the fungus is known to attack barley grass, wheat grasses, and other species of grass.

A potato leaf blotch fungus new to America, L. R. JONES (*Abs. in Science, n. ser.*, 25 (1907), No. 634, pp. 291, 292).—In this abstract, *Cercospora concors* is reported as occurring in 3 well separated stations in Vermont during 3 different seasons, the first being in 1902. In every case the fungus has been found in old gardens, and indications are that it is a well-established parasite on the cultivated potato and is probably widely distributed in the longer settled regions of the northeastern parts of the United States and Canada.

The fungus attacks are confined to the leaves, where it develops concurrently with the early and late blight fungi, to which it bears so close a resemblance in appearance that it has probably been overlooked heretofore. It is believed that spraying will hold it in check.

A detailed account of this new disease is promised in the report of the Vermont Station for 1906.

Some potato diseases, their cause and control, A. NELSON (*Wyoming Sta. Bul.* 71, pp. 39, figs. 11).—Descriptions are given of early and late blight or rot of potatoes, *Rhizoctonia* disease, which is widely distributed, and potato scab. For the prevention of these diseases, spraying with Bordeaux mixture is recommended for early and late blight, while soil and seed treatment and rotation of crops are suggested as remedies for the *Rhizoctonia* and scab.

The deep scab of beets, F. C. VON FABER (*Arb. K. Biol. Anst. Land u. Forstw.*, 5 (1907), No. 6, pp. 342-350, pl. 1).—The author briefly reviews some of the literature relating to the deep scab of beets, paying particular attention to the publications of Bolley (E. S. R., 3, p. 619), Frank (E. S. R., 10, p. 170), and others, after which he describes the anatomical structure of deep scab and considers the cause of the disease. Attention is called to the statement of Bolley that the deep scab is due to a bacteroid fungus. By the usual means the author has separated the organism, cultivated it in various media, and carried out successful inoculation experiments with pure cultures. He was unable to identify the organism with any known species and has named it *Bacterium scabigenum*, a technical description of which is given.

A study of disease resistance in watermelons, W. A. ORTON (*Abs. in Science, n. ser.*, 25 (1907), No. 634, p. 288).—A brief account is given of results of work on the watermelon wilt (*Neocosmospora vasinfecta nirca*). In studying this fungus the resistance of more than 100 varieties of American and Russian melons was tested and none of them proved to be immune. A hybrid between the watermelon and the citron or stock melon has been obtained, which in the third generation is said to have good edible qualities and at the same time is quite resistant to the fungus.

The use of common salt for the prevention of gummosis of fruit trees, E. VAN HECKE (*Jour. Soc. Agr. Brabant et Hainaut*, 52 (1907), No. 13, pp. 366, 367).—The author cites the observations of H. De Greeff in Zealand and C. Heime in China, both of whom claim that peaches, apricots, and similar fruit trees do not suffer from gummosis when grown near the sea or in soils containing appreciable quantities of salt.

Following this suggestion, experiments were conducted in which trees receiving 1, 2, and 3 lbs. of salt each were compared with others receiving none. At

the end of the season it was found that the tree receiving 3 lbs. of salt did not suffer at all from gummosis and the ones receiving 1 and 2 lbs. but slightly, while the fourth tree was severely injured, lost most of its branches, and bore little fruit as the result of the disease. It is planned to continue these experiments on a large scale to determine the actual value of the treatment.

Pear leaf blight (*Natal Agr. Jour. and Min. Rec.*, 9 (1906), No. 12, pp. 1135-1137, figs. 4).—An account is given of pear leaf blight due to *Entomospodium maculatum*, a fungus quite common in various parts of America and Europe, but which has only recently become very troublesome in South Africa. The effect of the fungus on the host plant is described and directions are given for spraying with Bordeaux mixture and ammoniacal copper carbonate solutions.

A new native host for pear blight, M. B. WAITE (*Abs. in Science*, n. ser., 25 (1907), No. 634, pp. 286, 287).—In connection with investigations carried on in California, the author reports having found that the pear blight organism (*Bacillus amylovorus*) attacks the California holly (*Heteromeles arbutifolia*). This adds another host plant to the list of those known to be subject to this disease.

Experiments on the control of black rot in Loire, L. ROUGIER (*Rev. Vit.*, 27 (1907), No. 694, pp. 369-372).—After describing the meteorological conditions and the invasion of black rot in 1906, an account is given of experiments made during the year for the control of the disease.

The vineyards were divided into 3 parts, one of which received 5 applications of acid copper acetate solution, another the same number of applications of Bordeaux mixture, while the third was held as a check. The acid solution of copper acetate was formed by adding $\frac{1}{2}$ liter of acetic acid to 1 kg. of neutral copper acetate, and diluted with 100 liters of water. The Bordeaux mixture was composed of 2 kg. of copper sulphate and 1 of lime to 100 liters of water. The first application of the fungicide was made May 23 and the last July 24.

A careful examination was made of the foliage and grapes, and it was estimated that there was a loss of 1 per cent where the vines were treated with the copper acetate solution, 5 per cent where treated with Bordeaux mixture, and 40 per cent where no treatment was given.

Some fungi of cacao trees, C. SPEGAZZINI (*Rev. Facult. Agron. y Vet. La Plata*, 2, ser., 2 (1906), No. 4-6, pp. 303-311, figs. 5).—Technical descriptions are given of a number of fungi reported on cacao trees the presence of which is considered detrimental to the growth of the trees. The species described are *Anthostomella bahiensis*, *Clypeosphaeria? theobromicola* n. sp., *Calospora? bahiensis* n. sp., *Latendrea bahiensis* n. sp., and *Hysteriopsis brasiliensis* n. g. and n. sp.

Lecture on rubber diseases, E. E. GREEN and T. PETCH (*Peradeniya Manuals*, 1906, No. 1, pp. 32-45).—Descriptions are given of a number of the more conspicuous insect and fungus pests of rubber. Among the fungi reported are *Botryodiplodia elastica*, which occurs on the roots of Hevea rubber, and *Fomes semitostus*, which is quite destructive on the same species of rubber. This fungus occurs on the stumps of quite a number of trees, from which it spreads to the Hevea, and it is advised that all such stumps should be removed, as far as possible, prior to planting. A discussion on this subject follows the presentation of this paper.

A root disease of Hevea brasiliensis, T. PETCH (*Circs. and Agr. Jour. Roy. Bot. Gard. Ceylon*, 3 (1906), No. 17, pp. 237-242, pls. 2).—The author reports the occurrence in one district of Ceylon of the root disease of *Hevea brasiliensis*, which is caused by the fungus *Fomes semitostus*. This fungus attacks the roots, and frequently associated with it are white ants, but these are believed to be secondary to the presence of the fungus. There appears to be no prelim-

inary indication of the disease, its presence being noticed only when the trees are nearly dead, when they frequently break off at or just below the surface of the ground. When the trees are examined the mycelium of the fungus will be found present, and often the sporophores may be observed either on the recently destroyed trees or on stumps that have persisted in the soil.

As there does not seem to be any means for detecting the presence of the fungus on young trees before they are dead, all remedial measures must be directed to preventing further losses. It is suggested that the diseased roots and lower portions of the trunks should be dug out and burned and trenches dug around the infected areas to prevent the fungus spreading laterally.

A plant tumor of bacterial origin, E. F. SMITH and C. O. TOWNSEND (*Science*, n. ser., 25 (1907), No. 643, pp. 671-673).—For about 2 years the authors have been carrying on studies of a tumor or gall which occurs on the cultivated marguerite, or Paris daisy. From diseased material the authors have succeeded in isolating bacteria, carried them through cultures, and by means of inoculation experiments have produced galls on other plants.

In some of their experiments 100 per cent of the inoculations gave positive results, while check plants, punctured but not inoculated, healed normally and remained free from galls. In addition to the marguerite the bacteria were found to develop small tumors in a few weeks on the stems of tobacco, tomato, and potato plants and on the roots of the sugar beet. It was also found that galls closely resembling the young stages of crown gall were produced on the roots of peach trees by needle pricks introducing this organism. The preliminary experiments have not been carried sufficiently far to enable the authors to say positively that their organism is the cause of the destructive crown gall of the peach, but the indications seem to point that way.

The organism causing these tumors has been designated as *Bacterium tumefaciens* n. sp., and a technical characterization of it is given.

Ray blight, a new chrysanthemum disease, F. L. STEVENS (*Abs. in Science*, n. ser., 25 (1907), No. 634, p. 291).—In a brief abstract the author reports having received specimens of chrysanthemums affected by a blight in which the ray flowers of the head were conspicuously attacked. The fungus, which belongs to the genus *Ascochyta*, is apparently undescribed. It also occurs on the stems. It was repeatedly isolated by plate cultures, and inoculation experiments conducted showed no difficulty in producing typical cases of disease.

Copper fungicides, E. RABATE (*Jour. Agr. Prat.*, n. ser., 13 (1907), No. 11, pp. 331-334).—The author discusses the relative efficiency of various fungicides, the comparative value of liquid and dry forms, and gives formulas for the preparation of many of the fungicides in common use, together with directions for testing their acidity, after which he discusses the proper quantities to be used, as shown by observations regarding efficiency, cost of material, difficulty of application, etc.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Experimental zoology, T. H. MORGAN (*New York and London: The Macmillan Co., 1907, pp. XII+154, pls. 2, figs. 26*).—Attention is called to the fact that the vast majority of zoologists have been and still are doing observational and descriptive work. The author believes that in point of development zoology is far behind chemistry and physics. This is believed to be largely due to the small amount of experimental work which has been carried on by zoologists. The advantages of the experimental method as applied to zoology

are set forth with numerous illustrations of the results obtained, and the experimental work thus far carried on in various fields of zoology is summarized in such a way as to show the present standing of this phase of zoology and the necessity of further work of the same character.

Birds and fruit growers, W. E. BEAR (*Jour. Bd. Agr. [London], 13 (1907), No. 11, pp. 665-671*).—The value of legislation in protecting beneficial birds is set forth. It is believed that reliable information should be obtained from fruit growers regarding those species of birds which are beneficial and those which cause most damage to fruit. Mention is made of certain species which are the chief offenders along this line.

Insects; their organization, development, habits, and economic relations, A. BERLÉSE (*Gli Insetti loro Organizzazione, Sviluppo, Abitudini e Rapporti Coll'uomo. Milan: Soc. Ed. Libreria, 1906, vol. 1, pp. 584, pls. 6, figs. 697*).—In this first volume of the author's comprehensive work on insects attention is given to a brief history of entomology, the variation in the size of insects, the general plan of their anatomical organization, embryology, general morphology, and a detailed discussion of the various anatomical features of the different systems of tissues.

Insects of the garden, A. F. CONRAD (*Texas Sta. Bul. 89, pp. 52, figs. 1/4*).—Numerous requests are received by the station for information on garden insects, and the present bulletin is prepared to answer these inquiries. The more important garden insects are described, with notes on their life history and recommendations regarding methods of treatment.

C. E. SANBORN discusses the melon aphid and other related insects, with notes on remedies. For combating the melon aphid considerable reliance may be placed in the use of rape as a trap crop. Other methods are suggested, particularly fumigation and the encouragement of the insect enemies of this pest.

How insects are distributed, L. CAESAR (*Canad. Ent., 39 (1907), No. 3, pp. 85-99*).—Attention is called to the unusual opportunities which insects have in modern times for becoming distributed as a result of extensive commercial operations.

Fifth annual report of the chief inspector, A. F. BURGESS (*Ohio Dept. Agr., Div. Nursery and Orchard Insp. Rpt. 1906, pp. 51*).—A brief historical statement is given of the conception and operation of the present nursery laws of Ohio, with mention of the defects and strong points. Statistics are also presented showing the extent of fumigation and other treatment applied by the inspector during the year, together with a list of the more important fruit pests and of the nurserymen of the State.

Western slope fruit investigation, 1906. Report of the field entomologist, E. P. TAYLOR (*Colorado Sta. Bul. 119, pp. 16*).—During the season of 1906 attention was directed chiefly to methods of controlling the codling moth. Little variation was observed in the habit of the moth in the different orchards. It appears that about 60 per cent of the first brood enter the apples at the calyx. The second application of the insecticide must be made early enough to coat the surface of the small apple before the larvæ attempt to enter through the side of the fruit. There are but 2 generations of the insect, and it is believed that 2 sprayings should be effective against the first brood, rendering the second brood of little importance.

The first application of arsenicals was made about the middle of May, the second about the first of June. If desirable, other applications may be given at the first of July, the middle of July, and the first of August.

Notes are also given on the peach-twig borer, apple aphid, woolly aphid, and

other insect pests. The buds of apple and pear trees were injured to some extent by *Myochrous squamosus*.

Insects of German East Africa, H. P. BERENBERG (*Natal Agr. Jour. and Min. Rec., 10 (1907), No. 1, pp. 50-55*).—A brief account of locusts, cotton insects, and the pests of castor-oil beans.

Report on the orchards and fruit plantations of Worcestershire, F. V. THEOBALD (*Worcester: Worcestershire Ed. Com., 1906, pp. 30*).—Notes are presented on the chief insect and fungus diseases observed in various orchards in different districts of Worcestershire. A list of 43 insects and 10 fungus diseases is given as found in the trips of inspection. Particular attention is devoted to the woolly aphid, green aphid, apple psylla, shot-hole fungus, etc. Insecticide treatment is recommended for apple psylla, woolly aphid, oyster-shell bark-louse, *Hyalopterus pruni*, *Aphis pruni*, etc.

Some miscellaneous results of the work of the Bureau of Entomology, IX. The Mexican conchuela in western Texas in 1905, A. W. MORRILL (*U. S. Dept. Agr., Bur. Ent. Bul. 64, pt. 1, pp. 1-14, pl. 1, figs. 2*).—*Pentatoma ligata* was reported as causing much damage to alfalfa, milo maize, cotton, and a number of other crops. Some injury was also observed on peaches and grapes. The life history and habits of this insect are discussed, with notes on its natural enemies, both parasitic and predaceous.

Where this bug occurs in large numbers it is inadvisable to attempt to ripen a crop of alfalfa seed during July and August. The only satisfactory method for combating this pest is by means of hand nets and various forms of jarring apparatus according to the crop attacked.

Some miscellaneous results of the work of the Bureau of Entomology, IX. Notes on the economic importance of sowbugs, W. D. PIERCE (*U. S. Dept. Agr., Bur. Ent. Bul. 64, pt. 2, pp. 15-22, pl. 1*).—Particular attention is given to a discussion of the life history and habits of *Armadillidium vulgare*, which, for several years, has been reported as causing injury to various crops in Texas. This species of sowbug attacks cotton, palmetto, cucumbers, hot-house vegetation, and other plants, but will also eat decayed vegetation and the eggs of cattle ticks.

It may most conveniently be combated by the use of poisonous baits, especially potato or bread poisoned with arsenicals and placed in locations where the sowbugs commonly congregate. Buildings may be freed of the pest by the use of carbon bisulphid.

An account is also given of the life history and habits of *Porcellio levis* and *Mctoponorthus pruinosis*.

Some miscellaneous results of the work of the Bureau of Entomology, IX. Notes on "punkies," F. C. PRATT (*U. S. Dept. Agr., Bur. Ent. Bul. 64, pt. 3, pp. 23-28, figs. 4*).—Observations were made on *Ceratopogon gullipennis* in Virginia. This gnat causes great annoyance to man and animals in localities where it occurs in large numbers. A detailed description is given of the insect in its various stages. The author also discusses other related species of this same genus.

A contribution to our knowledge of the Thysanoptera of California, D. MOULTON (*U. S. Dept. Agr., Bur. Ent. Bul. 12, pt. 3, tech. ser., pp. VI+39-68, pls. 6*).—In presenting an account of the Thysanoptera of California the author has found it necessary to erect a new genus *Orothrips*, and the genus *Megalothrips* is first recognized as having representatives in this country. Thrips attack a large variety of plants sometimes causing considerable injury. The attack of the pear thrips was the immediate occasion of the investigation reported in this paper.

A key is presented for the identification of families, genera, and species of this group found in California, and descriptions are given of all species recognized in the State.

Papers on the cotton boll weevil and related and associated insects. The cotton stalk-borer, A. C. MORGAN (*U. S. Dept. Agr., Bur. Ent. Bul. 63, pl. 7, pp. 63-66, pl. 1*).—Notes are given on the distribution, food plants, life history, natural enemies, and means of controlling *Ataxia crypta*. This insect feeds upon sunflower, cocklebur, figs, and various other plants, as well as cotton, but seldom causes serious injury. In one instance about 20 per cent of the stalks in a field of cotton was attacked. The remedy suggested is that of destroying the infested stalks early in the fall.

Papers on the cotton boll weevil and related and associated insects. Notes on the pepper weevil, F. C. PRATT (*U. S. Dept. Agr., Bur. Ent. Bul. 63, pl. 5, pp. 55-58, pl. 1, fig. 1*).—*Anthonomus uncinatus* caused great injury to nearly all varieties of peppers in the region of San Antonio, Texas, but later the pest practically disappeared in some of the worst infested districts. This insect was apparently introduced from Mexico within recent years. The infested pepper pods show a slight proliferation of tissue, which assists in checking the work of the larva, but in cases of bad infestation it is necessary to collect and destroy fallen pepper pods or bury them by cultivation.

Enemies of rice (Bul. Écon. Indo-Chine, n. ser., 9 (1906), No. 59, pp. 116½-1173, figs. 20).—Special attention is given to two moths (*Cnaphalocrocis medinalis* and *Diatraea sacchari*). These pests cause serious damage to rice throughout Indo-China and can not be readily controlled by the methods which have thus far been devised. It is impossible to use irrigation as a means of control late enough to be effective against the insects without injuring the rice. The use of lantern traps has not produced very satisfactory results. The author therefore recommends the collection and destruction of all infested stools of rice at the time when the caterpillars are located at the base of the stems.

Experiments with Calandra oryzae, B. WAHL (*Ztschr. Landw. Versuchs. Österr., 10 (1907), No. 2, pp. 57-70*).—A series of experiments was carried out to determine the food requirements of the rice weevil. It appears that this pest will feed upon corn, wheat, rye, barley, and rice, as well as a number of milling products, bread made from them, and macaroni. It does not breed, however, except in the 5 varieties of grains mentioned. In preventing its spread, it is desirable to keep close watch for infested grain and to apply suitable treatment at once.

Insect pests and diseases of sugar beets in 1906, O. FALLADA (*Separate from Österr. Ungar. Ztschr. Zuckerindus. u. Landw., 1907, No. 1, pp. 8*).—During the year under report the chief insect pests of sugar beets were wireworms, cockchafer, species of *Cleonus* and *Haltica*, cutworms, and plant lice. Brief notes are given on the habits of these pests. Short accounts are also presented of nematode worms, bacteriosis, scab, root rot, leaf yellows, leaf spot, and other fungus diseases.

Lita ocelletella and its injury to sugar beets in 1906, P. MARCHAL (*Sucr. Indig. et Colon., 69 (1907), No. 10, pp. 259-263*).—This insect in the larval form tunnels in the petioles of the leaves and in the outer portion of the sugar beets, particularly at the crown. In this way a great amount of damage is done. In preventing the ravages of this pest, it is recommended that crowns with leaves should be removed from the infested beets and used for feeding or ensiling in order to destroy the insects. In badly infested regions, it may also be necessary to adopt a system of crop rotation.

The cabbage maggot and other injurious insects of 1906, F. L. WASHBURN (*Minnesota Sta. Bul. 100, pp. 87, pls. 7, figs. 57*).—The material contained in this bulletin has already been noted from another source (E. S. R., 18, p. 749).

The oriental moth, a recent importation, H. T. FERNALD (*Massachusetts Sta. Bul. 114, pp. 14, pl. 1, fig. 1*).—Early in 1906 cocoons were found on several kinds of fruit trees in Dorchester, Massachusetts, which subsequently proved to be *Cnidocampa flarescens*. This insect was most abundant near a locality where a Japanese nursery had previously been maintained and has become distributed to a distance of 2 miles in one direction and nearly 1½ miles in the other. The pest occurs on Norway maple, as well as other kinds of maple, and also on pear, apple, cherry, and crab-apple trees, and various species of forest trees. As many as 100 cocoons have been found on a single tree.

The oriental moth was apparently introduced before 1900. There is one brood annually, and the moths appear in June and July. The insect is described in all its stages. It has a wide distribution in the Orient and could probably thrive in almost any part of the United States. It is still doubtful whether it will prove a serious pest.

Preliminary report on cranberry insects, H. J. FRANKLIN (*Massachusetts Sta. Bul. 115, pp. 15*).—A careful study was made of the remedies best adapted for controlling the chief insect enemies of the cranberry.

For the cranberry fruit worm on bogs which have an abundant water supply the author recommends flooding immediately after picking and drawing off the winter flowage early in April. On bogs with a limited water supply it is recommended that the winter flowage be turned on as soon as possible after the cranberry foliage has ripened. Arsenate of lead must be used as a spray on bogs which do not admit of flooding with water in winter.

In treating the fireworm on bogs with a good water supply, the winter flowage may be drawn off about the middle of April and the worms, which normally hatch after this period, may be destroyed by spraying with arsenate of lead.

If the false army worm appears in large numbers, it is desirable to reflow the cranberry bogs for 24 to 36 hours soon after May 15. This may be repeated if necessary. Dry bogs should be sprayed with arsenate of lead early in May.

The yellowhead cranberry worm may be controlled by holding on the winter flowage until after May 20 or by spraying dry bogs with arsenate of lead about May 15 and July 4.

A brief account is also given of methods of treatment for the cranberry girdler and spittle insects.

Poisoned bait for the fruit fly, T. F. DREYER (*Agr. Jour. Cape Good Hope, 30 (1907), No. 2, pp. 192-194*).—A formula has already been suggested by Berlese for the preparation of a poisoned bait for killing the fruit fly, this bait consisting of 31 per cent of honey, 65 per cent of molasses, 2 per cent of glycerin, and 2 per cent of arsenite of potash. While it is believed that this formula would be of service in South Africa, another is suggested calling for 1 lb. of arsenate of lead and 5 gal. of sirup in 25 gal. of water.

Treatment for the olive fly, G. BATTANCHON (*Prog. Agr. et Vit. (Ed. l'Est), 28 (1907), No. 9, pp. 264-266*).—Arsenical treatments are admitted to have given good results in the treatment of the olive fly, but the author seems to recognize the prejudice against the use of arsenic on olives, and suggests that the immediate collection of all infested olives which fall from trees and the disinfection of storehouses where olives are kept might yield satisfactory results.

A viviparous fly with larvæ sometimes parasitic and sometimes vegetarian, J. K. D'HERCULAIS (*Compt. Rend. Acad. Sci. [Paris], 144 (1907), No.*

7, pp. 390-393).—In Algeria the larvæ of a fly had already been observed as a parasite on grasshoppers and referred to the species *Anthomyia cana*. The author observed another species of this genus, which is believed to be *A. cili-erura*, as a parasite on *Schistocerca americana* in the Argentine Republic. It is believed that this species has a wide distribution.

The apple and pear mites, P. J. PARROTT, H. E. HODGKISS, and W. J. SCHOENE (*New York State Sta. Bul.* 283, pp. 281-318, pls. 10).—In a study of the mites on apple and pear leaves, 5 species have been recognized: *Eriophyes malifolia*, *E. pyri*, *E. pyri variolata*, *Phyllocoptes schlechtendali*, and *Epitrimerus pyri*. *Eriophyes pyri*, commonly known as the leaf-blister mite, is the most abundant and the most injurious species. The structure, habits, and systematic position of these pests are discussed and a list is given of all American species of the family with their host plants and an analytical table for their identification.

Particular attention is given to *E. pyri*, which produces the well-known blister spots on the leaves of pear and apple trees. On apple trees the blisters may have a reddish tinge, but usually are less brilliant. The mites injure the fruits and fruit stems as well as the leaves, and have been found on 250 varieties of apples. After a little experience the injuries caused by mites may be readily distinguished from those due to spraying or to the apple rust. A parasitic mite was found preying upon the blister mite and is described as a new species under the name *Scius pomi*.

In experiments on apple trees a comparison was made between kerosene oil, miscible oil, kerosene emulsion, whale-oil soap, and the sulphur washes, the latter being prepared according to various formulas. On account of its harmlessness, cheapness, and efficiency, kerosene emulsion diluted with 5 parts of water and applied during the dormant season is recommended as the most practical remedy for the treatment of apple orchards infested with the blister mite. In pear orchards this pest may be controlled by proper pruning and by spraying with kerosene emulsion in the fall or spring.

The blister-mite and its allies, F. H. HALL ET AL. (*New York State Sta. Bul.* 283, popular ed., pp. 10, figs. 6).—A popular summary of the above bulletin.

The aphides affecting the apple, A. L. QUAINANCE (*U. S. Depl. Agr., Bur. Ent. Circ.* 81, pp. 10, figs. 8).—The aphides which are known to attack apple trees in the United States are *Schizoneura lanigera*, *Siphocoryne avenæ*, *Aphis mali*, and *Aphis malifolia*. The appearance, life history, and distribution of each of these pests are briefly discussed.

Little practical good has resulted from the use of strong lye water, whale-oil soap, kerosene, or crude petroleum in the control of apple aphides. Lime-sulphur wash gave good results in experiments by J. M. Aldrich. Formulas are given for the preparation of some of these insecticides.

The San José scale, A. F. CONRADI (*Texas Sta. Bul.* 87, pp. 11, figs. 4).—A brief popular account of the appearance, life history, habits, and food plants of the San José scale and of the means of combating it. Directions are given for the preparation and application of lime-sulphur wash, whale-oil soap, kerosene, crude oil, and other insecticides. The lime-sulphur-salt wash, prepared according to the formula 15-15-15-50 and boiled for 45 minutes, gave excellent results. A lime-sulphur wash with the same proportion of lime and sulphur also proved very satisfactory.

The San José scale and experiments for its control, H. T. FERNALD (*Massachusetts Sta. Bul.* 116, pp. 22, fig. 1).—Brief historical and biological notes are given on this pest. The author summarizes the results of spraying experiments to control the San José scale from 1902 to date. Some of this material is reproduced from Bulletin 86 of the station (E. S. R., 14, p. 1095).

The San José scale is at present found nearly everywhere in Massachusetts and feeds on 125 or more different kinds of plants. Its natural enemies do not keep it in check, and it is, therefore, necessary to cut down worthless, badly infested trees and burn them and to fumigate or spray other infested trees. In spraying the best results are obtained with lime-sulphur wash boiled from 40 minutes to 1 hour. Self-boiling lime-sulphur mixtures are less satisfactory. Likewise the K-L mixture has not given success. Proprietary insecticides for the San José scale either give poor results or are so expensive as to be out of the question.

How to control the San José scale and other orchard pests, J. TROOP and C. G. WOODBURY (*Indiana Sta. Bul.* 118, pp. 395-423, figs. 14).—Formulas are presented for the preparation of standard insecticides and fungicides, and a list is given of the more important of the insect diseases affecting the apple, cherry, gooseberry, grape, peach, pear, plum, raspberry, blackberry, and strawberry.

The present status of the San José scale in Indiana is outlined and the insect is described. Lime-sulphur wash is recommended as the best treatment for this pest.

How nurserymen may guard against San José scale, F. SHERMAN, JR. (*N. C. Crop Pest Com. Circ.* 11, pp. 11).—Brief directions are given for the care of buds and cuttings, the spraying of nursery stock, and other lines of work to be taken up by nurserymen who wish to maintain premises free from San José scale.

The cottony maple scale in Illinois, S. A. FORBES (*Illinois Sta. Bul.* 112, pp. 343-360, pls. 3, figs. 8).—The cottony maple scale is seldom injurious to maple trees in natural forests, but causes great damage to trees planted along streets and roadsides for shade purposes. In Chicago it has been injurious continuously since 1886. It is particularly harmful to soft maple, but attacks also linden, box elder, elm, and a considerable variety of other trees. The life history and habits of this pest are discussed in some detail.

A brief summary is given of insecticide work thus far carried on by the author and others in its control. Kerosene emulsion was applied at a strength of 10 per cent in 1 experiment, and whale-oil soap at the rate of 1 lb. to 6 gal. of water was applied on a single tree. The insecticides were applied in July, and a comparison of the results showed that 33 per cent of the scales were killed by an application of kerosene emulsion at the beginning of the hatching period and 82 per cent by 2 applications at the middle and end of that period. Whale-oil soap was somewhat less effective.

The author concludes that for summer spraying a 10 per cent kerosene emulsion applied at the middle and end of the hatching period will give satisfactory results. The cost of this treatment for average trees is about 32 cts. each. In experiments carried on in Chicago the average cost for both materials and labor was 43 cts. per tree.

An application of a 19 or 20 per cent kerosene emulsion during the dormant season caused considerable injury to trees, some of which looked sickly in the spring and others died. The percentage of scales killed by the winter treatment ranged from 86 to 91.

The strawberry weevil in the South-Central States in 1905, A. W. MORRILL (*U. S. Dept. Agr., Bur. Ent. Bul.* 63, pt. 6, pp. 57-62).—Since the strawberry weevil belongs to the same genus with the cotton-boll weevil it was thought desirable to ascertain whether there were any native parasites of the strawberry weevil in the cotton belt which might attack also the cotton-boll weevil. The study of the subject, as thus far conducted, has been confined largely to a determination of the prevalence and distribution of the strawberry

weevil in the Southern States, particularly in Texas, Louisiana, and Arkansas. In many localities the strawberry weevils were found to be comparatively rare, which is taken as indicating parasitism.

The poplar and willow borer (*Cryptorhynchus lapathi*), W. J. SCHOENE (*New York State Sta. Bul.* 286, pp. 83-104 pls. 6).—The imported poplar and willow borer has been known in the United States since 1882 and recently has been reported from Massachusetts to North Dakota. It attacks nearly all species of poplar, willows, and alders, and is a serious pest not only to shade trees but to the willow basket business. The insect is one-brooded and the adult beetles begin to appear about the middle of July.

In controlling this pest it is advisable to avoid making new plantations of poplar and willow near old ones. Badly infested trees or parts of trees should be cut and burned in June before the adult beetles appear. The same treatment should be given to all infested branches and trees broken by the wind. In nurseries it is believed that considerable benefit will follow the application of Bordeaux mixture containing an arsenical poison during the month of July. Preliminary experiments indicate that the beetles which feed upon plants treated in this way are killed within 3 or 4 days.

An enemy of poplars and willows, F. H. HALL (*New York State Sta. Bul.* 286, popular ed., pp. 8, figs. 10).—A popular summary of the above bulletin.

Insect injury to cacao beans, L. REH (*Ztschr. Wiss. Insektenbiol.*, 3 (1907), No. 1, pp. 21-25).—Notes are given on the injury caused to cacao beans by the attacks of *Ephestia clutella* and *Aracoccus fasciculatus*. Attention is called to the life history and habits of these insects and bibliographical references are added.

The spotted locust (*Aularches miliaris*), E. E. GREEN (*Circs. and Agr. Jour. Roy. Bot. Gard. Ceylon*, 3 (1906), No. 16, pp. 227-236, pl. 1).—In various parts of Ceylon this insect appears in large numbers and causes injury to various cultivated plants. Their favorite food seems to be *Erythrina lithosperma*, but they also attack various other trees. The pest is not observed to be doing any serious harm to tea, cacao, or rubber.

Notes on spraying and suggestions for combating crop pests, E. WALKER (*Arkansas Sta. Bul.* 95, pp. 49-89).—This bulletin contains practical directions for farmers, gardeners, and fruit growers for the preparation and application of the standard fungicides and insecticides. Notes are also given on spray pumps and their use, and a list is presented of the common field, garden, and fruit crops with the diseases and insect pests to which they are most subject and the remedies to be applied.

The breeding of bees, E. F. PHILLIPS (*Amer. Breeders' Assoc. Proc.*, 2 (1906), pp. 60-65).—In recent years a considerable variety of bees have been introduced into this country, so that at present we have German, Italian, Cyprian, Carniolian, Holy Land, Tunisian, Banat, Caucasian, and Dalmatian races of bees. This gives opportunity to test the value of a number of hybrids, and some work along this line has already been done. Attention has been given in bee breeding to increasing the length of the tongue, to the capacity for honey collection, and to other points, including efforts to produce non-swarming bees, and to obtain more gentle races. The indiscriminate mixture of races does not give satisfactory results, but occasionally the first cross is better than either parent. It is recommended that bee raisers should produce their own queens.

Sericultural experiments at Shillong, B. C. BASU (*Agr. Jour. India*, 2 (1907), No. 1, pp. 22-32).—European one-brooded silkworms were introduced into India to test their adaptability to the climate. At Shillong the winter tem-

perature ranged from 38 to 60° F., but fell below 50° at some time during each day. If the temperature remains above 50° F. for 2 weeks or more during winter, the European silkworm is likely to begin development. This can not be checked, and the moths may, therefore, appear too early in the spring. Nothing of this sort happened at Shillong, and the race appears to be well adapted to that climate.

In a test of large and small leaf mulberries the size and weight of the cocoons were less when the large leaf variety was used for food.

The coloring matter of the silk of *Saturnia yama-mai*, C. GAUTIER (*Compt. Rend. Soc. Biol. [Paris]*, 62 (1907), No. 6, pp. 237-236).—A study of the silk of this species shows that it is green and that under the microscope, after samples have been mounted in glycerin jelly, amorphous bodies are found which are not comparable to the crystals sometimes observed in large numbers in the normal cocoon.

FOODS—HUMAN NUTRITION.

The dynamics of living matter, J. LOEB (*New York: The Macmillan Co., 1906, pp. XII + 233, figs. 64*).—This work constitutes volume VIII of the Columbia University Biological Series and summarizes and treats of the author's extensive investigations in experimental biology. The lectures include discussions of the general chemistry of life phenomena, the general physical constitution of living matter, some physical manifestations of life, the rôle of electrolytes in the formation and preservation of living matter, the effects of heat and radiant energy upon living matter, heliotropism, facts concerning tropisms and related phenomena, fertilization, heredity, and the dynamics of regenerative processes.

Personal hygiene, M. LE BOSQUET (*Chicago: American School of Home Economics, 1907, pp. VIII + 232, figs. 34*).—The structure of the body, bones, muscles, nervous system, etc., the running of the body machine, the digestion of food, respiration, nutrition, temperature regulation, the care of the body machine, the hygiene of the nervous system, and of feeding, the care of the teeth, and related questions are taken up in this handbook of hygiene, which is designed primarily as a text-book for instruction by correspondence.

The volume as a whole constitutes a useful summary of data on this very important subject.

Food and hygiene, W. TIBBLES (*London: Rehnman, Ltd., 1906, pp. XII + 672*).—The author has discussed food, air, and water with special reference to the needs of physicians and their patients. Composition and digestibility of food, food requirements at different ages and under different circumstances, dietetic treatment of diseases, and related questions are considered. An appendix gives dietary standards, factors for digestibility, and tables showing the composition and fuel value of foods.

The home economics movement, ISABEL BEVIER and SUSANNAH USHER (*Boston: Whitcomb & Barrows, 1906, pt. 1, pp. 67*).—In this historical account of the home economics movement in the United States, the authors have traced its growth in agricultural colleges, State universities, cooking schools, and public schools. The information summarized is of decided importance to teachers and students of home economics.

Early attempts were made to introduce home economic branches into schools of various kinds in this country, but the movement first took definite form about 1870. Among State institutions the 3 pioneers in the work were the Iowa State College, the Kansas Agricultural College, and the University of Illinois.

The rational feeding of infants from birth to 2 years, MICHEL and PERRET (*Rev. Hyg. et Méd. Infant.*, 5 (1906), No. 6, pp. 477-679, pls. 2, figs. 7).—The authors have attempted to establish a scientific ration for the artificial feeding of infants between birth and 2 years of age. They have taken as a basis for their calculation a large amount of experimental and empirical data, which they summarize regarding the average weight of new-born infants, the gain in weight during different periods, the nature of the gain in terms of the composition of the body, the amount and character of material ingested and egested by infants breast fed and nourished on cow's milk diluted with water and sweetened with milk sugar, the amount of energy eliminated by infants per kilogram of body weight and per square meter of body surface, etc.

According to the calculations which are given, an infant weighing 8 kg. has a surface area of 3.696 square meters, and on the basis of 150 calories per square meter would require 554 calories of available energy for maintenance. The calculated amount of nitrogen necessary for a gain of 1 gm. in body weight is 0.02179 gm. A ration is proposed which can be modified to provide for the proper maintenance and growth, in accordance with the different weights of the infant at different periods. Observations of the effects of feeding a number of infants in accordance with the method proposed are reported.

The publication comprises a very comprehensive and valuable treatise of the rational feeding of infants.

Fruit recipes, R. M. BERRY (*New York: Doubleday, Page & Co., 1907, pp. XX+341, pl. 1, figs. 63*).—The composition and food value of fruits of temperate and tropical regions are discussed and information is summarized with reference to the origin, cultivation, and distribution of fruits and related topics. The bulk of the volume is given up to recipes for various fruit dishes and to a discussion of the use of fruits in various ways. The numerous illustrations refer particularly to the tropical and lesser known fruits. A detailed index adds to the value of the volume.

Concerning the vegetarian diet, R. STÄHELIN (*Corbl. Schweiz. Aerzte*, 36 (1906), No. 13, *Beilage*, pp. 405-417; *abs. in Zentbl. Physiol.*, 20 (1906), No. 17, p. 574).—A comparison of vegetarian and meat diets from the standpoint of energy value and also with respect to their influence upon the nervous system, circulation of the blood, muscular work, renal activity, etc.

Studies of the composition of flesh upon different diets, M. MÜLLER (*Arch. Physiol.* [Pflüger], 116 (1907), No. 3-4, pp. 207-228).—The experiments which were made with dogs, in the author's opinion, showed that there is a specific nitrogenous substance characteristic of fattened animals which differs from muscle protein in that it shows a narrower ratio of nitrogen to carbon.

Fresh flesh of animals in good condition for slaughter when freed from visible fat is relatively rich in carbohydrates and shows a low water content, while its nitrogen content is little increased. The abundance of carbon is due to a deposit of fat in the cells, since the flesh freed from fat shows a carbon content less than normal. Well fattened flesh owes its quality very largely to the presence of the nitrogenous material characteristic of fattened flesh referred to above, and the deposition of fat in the tissue and the increased amount of dry matter are not, as is commonly supposed, the only differences between well fattened and unfattened meat.

In calculating nitrogen balances no serious error is introduced if it be assumed that the nitrogen is added in the form of muscle protein.

In the author's opinion, his experiments help to explain the retention of nitrogen so often observed on a diet rich in protein. He considers it possible that the increased carbon dioxide output which is noted on such a diet has to do

with this nitrogen "fattening substance," and implies a cleavage of protein in which a product rich in nitrogen is retained in the body cells while the remainder of the molecule must be eliminated.

The extractives of muscle. VII, Concerning certain carnitin compounds, R. KRIMBERG (*Ztschr. Physiol. Chem.*, 50 (1907), No. 3-4, pp. 361-373).—The experimental data led the author to conclude that perhaps carnitin is a homologue of betain, and a graphic formula is suggested.

One hundred and one Mexican dishes, MAY E. SOUTHWORTH (*New York and San Francisco: Paul Elder & Co., 1906, pp. IV+86*).—Recipes are given for the preparation of a number of Mexican foods, including soups, fish, meat, vegetables, desserts, and a number of special dishes.

German cookery for the American home, ELLA OSWALD (*New York: Baker & Taylor Co., 1907, pp. XVI+236*).—Recipes for the preparation of soups, meat dishes, cakes, puddings, etc., are presented. According to the author the recipes selected include only those for which the ingredients may be easily procured. A detailed table of contents is given in both English and German.

The hay-box cooker (*Cornell Reading Course for Farmers' Wives, 5. ser., No. 23, p. 446*).—A brief description is given of the so-called hay-box cooker, in which tightly covered vessels containing boiling hot food are surrounded by non-conducting materials, so that the heat is retained and the food materials slowly cooked.

The fireless cooker (*Amer. Agr., 79 (1907), No. 1, p. 27*).—On the basis of personal experience a fireless cooker or hay box of home manufacture is described. It is stated that this device proved very satisfactory, lessening the labor of preparing food and effecting a considerable saving in labor and fuel.

Food adulteration in Texas, G. S. FRAPS (*Texas Sta. Bul. 91, pp. 24*).—The texts of the State pure-food law and the Federal law are given. Chemical preservatives, coloring matter, saccharin, and similar materials are described, and the results of the examination of a number of samples of sausage, olive oil, jelly and preserves, molasses and similar goods, vinegar, flavoring extracts, lard, canned goods, etc., are reported.

"Our examination of samples of food collected on the markets of Texas leads to the conclusion that there is a considerable amount of adulteration in certain classes of foods. Many of these adulterations are harmless, but are to be condemned, as they deceive the purchaser and provide him with an article other than what he supposes he is purchasing."

Bacteria of blown tins of preserved food (*Jour. Hyg. [Cambridge], 6 (1906), pp. 248-250; abs. in Jour. Chem. Soc. [London], 90 (1906), No. 528, p. 699*).—The organisms found were intestinal bacteria and produced fermentation when reintroduced into sound cans. The fermented canned sardines, salmon, and beef did not produce toxic symptoms when fed to guinea pigs.

Tomato catsup, T. MACFARLANE (*Lab. Inland Rev. Dept. [Canada] Bul. 129, pp. 13*).—Examination of 49 samples of tomato catsup collected in Canada showed that 8 were unadulterated. In 23 of the remainder adulteration was doubtful, while 18 were adulterated. The range in total solids was considerable, according to the analyses, varying from 7.44 to 29.04 per cent. There were also decided variations in the constituents making up the solids.

Following one of the ordinary recipes, catsups were made from apple, turnip, and pumpkin pulp, and analyses of these goods are reported. In composition they did not differ materially from the tomato catsups.

Analyses of American malt vinegar, A. G. WOODMAN and G. P. SHINGLER, JR. (*Technol. Quart., 19 (1906), No. 4, pp. 404-407*).—As shown by the analyses of 7 samples, American malt vinegars have a specific gravity of 1.0159, and

contain, on an average, 5.48 per cent total acetic acid, 2.46 per cent total solids, 0.24 per cent total ash, 0.11 per cent ash soluble in water, 0.09 per cent insoluble ash, 1.39 per cent reducing sugars (maltose) before inversion, 1.02 per cent reducing sugars after inversion, and 0.37 per cent protein. The polarization number is 2.38, the percentage of P_2O_5 in total solids, 2.29, and the ratio of soluble to insoluble P_2O_5 , 1:0.890. Data are also reported regarding the alkalinity of the ash and other characteristics.

Common salt, T. MACFARLANE (*Lab. Inland Rev. Depl. [Canada] Bul.* 128, pp. 13).—The examination of a large number of samples of salt collected in the Canadian provinces showed that they contained from 93 to 98 per cent sodium chlorid. Six of the samples examined contained foreign substances soluble in water, apparently added to prevent the salt from caking. Under the Canadian law this addition, in the author's opinion, does not constitute adulteration. "Nevertheless it would seem to be necessary that these brands should each, on selling, be labelled as a mixture."

Concerning sour milk, J. R. TARCHANOW (*St. Petersburg, 1906; abs. in Chem. Ztg., 30 (1906), No. 97, Reperit. No. 50, p. 430*).—A discussion of Metschnikow's theories regarding the therapeutic and hygienic value of sour milk and other foods containing lactic acid. A method of preparing sour milk in the household by the aid of lacto-bacilli is described by the author. In his opinion such an article is an important addition to the diet.

Condensed vegetable milk, T. KATAYAMA (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1906), pp. 113-115; abs. in Jour. Chem. Soc. [London], 90 (1906), No. 530, II, p. 889*).—The condensed milk referred to is prepared by concentrating soy-bean milk in a vacuum after the addition of 150 gm. of sucrose and 1 gm. per liter of dipotassium phosphate. The product, according to the author, has considerable food value and can be used in preparing various dishes.

The presence of vegetable milk in ordinary condensed milk can be detected by the addition of sodium carbonate, which produces a yellow coloration, or by adding 2 volumes of water, a few drops of dilute sulphuric acid, and distilling when the characteristic odor of raw soy beans is noticeable.

Vegetable cheese from the proteid of the soy bean, T. KATAYAMA (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1906), pp. 117-119; abs. in Jour. Chem. Soc. [London], 90 (1906), No. 530, II, p. 889*).—Vegetable cheese was prepared by mixing pressed tofu (made from soy beans), sodium chlorid, lactose, and Swiss cheese, the latter being added to introduce bacteria. In one experiment some casein was also added. The mixture was kept moist at 15° C. for 5 months. The resulting cheese was gray and free from holes, even when a considerable amount of lactose was used. It did not resemble Swiss cheese in flavor.

Cocoonut fat from a culinary standpoint (*Vyestnik Shivor. Promysch., 7 (1906), p. 103; abs. in Chem. Ztg., 30 (1906), No. 97, Reperit. No. 50, pp. 430, 431*).—It is stated that the expressed fat of the cocoonut is used to a considerable extent in Russia under the name of "plantol." According to the data summarized, some 96 per cent of this fat is assimilated by man, a value which is only slightly less than that which has been obtained for butter. Cocoonut fat consists of about 84 per cent of triglycerids of myristic and lauric acid with 12 per cent of olein and small quantities of other fatty acids in similar bodies.

The principal results obtained in the scientific study of human nutrition, J. KÖNIG (*Ztschr. Untersuch. Nahr. u. Genussmitl., 10 (1906), No. 12, pp. 577-588*).—An historical account of the progress of investigations of special importance in connection with human nutrition, presented at the first Congress of Food and Human Nutrition, Paris, 1906.

Progress in nutrition, C. F. LANGWORTHY (*Lake Placid Conf. Home Econ. Proc., 8 (1906), pp. 60-64*).—A brief summary of the nutrition investigations

carried on during 1905-6, particularly those conducted under the auspices of the Office of Experiment Stations.

Nutritive requirements of the body, F. G. BENEDICT (*Lake Placid Conf. Home Econ. Proc.*, 8 (1906), pp. 64-76).—A summary and discussion of the author's investigations which led to the conclusion that the commonly accepted dietary standards should not be appreciably lowered, especially as regards energy. A fuller account of the investigations has been previously noted (E. S. R., 18, p. 464).

Dietetic experiments at Yale University, I. FISHER (*Lake Placid Conf. Home Econ. Proc.*, 8 (1906), pp. 76-78).—Nine healthy students were the subjects of an investigation covering 18 weeks, in which freedom of choice of food materials was given and very thorough mastication was insisted upon.

The author notes that the quantities of food eaten were less than usual, that the diet supplied less nutritive materials than are called for by the commonly accepted dietary standards, and that there was an especially marked diminution in the quantity of flesh foods desired. The men led sedentary lives and took practically no exercise. Gymnasium tests at the beginning and end of the experiments showed that their endurance was markedly increased. In the author's opinion this is to be attributed to the character of the food and the way in which it was eaten. Control experiments were not made. The paper is followed by a discussion.

Physiological economy in nutrition, I. FISHER (*Science, n. ser.*, 24 (1906), No. 620, pp. 631-633).—The investigations briefly reported are noted above.

A respiration calorimeter, LETULLE and Mlle. POMPILIAN (*Compt. Rend. Acad. Sci. [Paris]*, 143 (1906), No. 23, pp. 932, 933, *dgm.* 1).—A respiration calorimeter of special construction is briefly described. It consists essentially of a chamber of glass and iron surrounded by 2 outer wooden walls. By means of the air spaces between these walls the temperature of the inside and outside of the respiration chamber is kept the same. The heat produced in the respiration chamber is taken up by a current of water passing through the calorimeter. It is stated that the regulation of the temperature of the calorimeter and the surrounding air spaces is automatic and that any temperature between 12 and 24° C. may be maintained in the chamber. According to results of electrical calibration tests the calorimeter will measure heat with an accuracy of 99.5 per cent.

As a respiration apparatus, the instrument described is of the closed-circuit type, the ventilating air current being maintained by means of a pump. Devices are provided for absorbing the water and carbon dioxide of the respired air and for replacing the oxygen withdrawn from the air.

The published description does not give details of the method of construction nor of the operation of the respiration calorimeter.

The respiration apparatus in the new physiological institute at Helsingfors, R. TIGERSTEDT (*Skand. Arch. Physiol.*, 18 (1906), No. 3-4, pp. 298-305).—The respiration apparatus which has been recently constructed at Helsingfors is similar to the instrument at the Carolien Medical-Surgical Institute at Stockholm previously described (E. S. R., 8, p. 242). As shown by control experiments in which candles were burned in the respiration chamber, the instrument is sufficiently accurate for experimental purposes. The experimenters recognize that the experimental periods should not be of too short duration.

Concerning gastric juice secretion, B. LÖNNQVIST (*Skand. Arch. Physiol.*, 18 (1906), No. 3-4, pp. 194-262, *dgms.* 3).—The numerous experiments reported were made with a dog which had been operated upon by the Pawlow method to produce a so-called small stomach:

The secretion of gastric juice, the author concludes, is brought about by psychic stimulation as well as by the action on the mucous membrane of the stomach and intestine of a number of chemical substances. In general, fat hindered the secretion of gastric juice. Water, alcohol, digestion products of protein, and meat extract caused an abundant secretion. Hydrochloric acid, having a strength of 0.1 to 0.5 per cent and normal gastric juice both affected the secretion very little. On the other hand, 0.5 per cent solutions of lactic acid and butyric acid produced an abundant secretion, and common salt and bicarbonate of soda caused secretions dependent upon the concentration of the solution used. Saliva and gall stimulated secretion in about the same degree as water. Gall, however, precipitated pepsin and so stopped digestion.

Natural digestion, it was found, takes place more rapidly and completely than artificial digestion, partly because the freshly secreted gastric juice comes into more intimate contact with the proteid material owing to stomach movements than is the case in vitro, and partly because the products of digestion are removed from the stomach soon after they are formed.

Other questions were also considered. An extended bibliography is appended to the report.

Investigations on the effect of common salt on the chlorin content of gastric juice, J. WOHLGEMUTH (*Arb. Path. Inst. Berlin, 1906, p. 561; abs. in Centbl. Med. Wiss., 1907, No. 1, p. 3*).—The experiments reported were made with a dog having a so-called Pawlow small stomach.

The chlorin content of the food was found to have a marked effect upon the stomach secretion dependent in considerable measure upon the character of the material fed. In general, it may be said that the normal stomach mucous membrane endeavors to keep the concentration of the gastric juice constrained within narrow limits and to so regulate the hydrochloric-acid content that it shall not become too high nor too low.

On the effect of bile upon the hydrolysis of esters by pancreatic juice, A. S. LOEVENHART and C. G. SOUDER (*Jour. Biol. Chem., 2 (1907), No. 5, pp. 415-425*).—Among the conclusions which were drawn from the artificial digestion experiments made with ox gall were the following:

"Bile salts, lecithin, and bile greatly accelerate the action of pancreatic juice on all of the esters studied, including olive oil.

"The optimum concentration for the bile salts when the lower esters are used is about 0.1 per cent, while for olive oil the optimum is from 2 to 4 per cent. In the latter concentration the bile salts greatly inhibit the action on triacetin, and the acceleration of the hydrolysis of ethyl butyrate is much less than when they are employed in greater dilution.

"Different specimens of juice and different experimental conditions altered greatly the degree of acceleration observed and the relative activity of the bile salts and lecithin.

"We advance no theory to account for the acceleration noted with these substances. While we believe that their action depends to a certain extent on their solvent action, it seems that in addition to this they accelerate the action of the enzym in some other way."

Synthesis of food protein in the liver, E. FREUND and G. TOEPFER (*Ztschr. Expt. Path. u. Ther., 3 (1906), No. 3, pp. 633-637*).—The investigations reported led to the conclusion that synthesis of protein takes place in the liver and that an abundant supply of blood through the portal vein is a necessary condition to its formation.

The relation of the kidneys to metabolism, F. A. BAINBRIDGE and A. P. BEDDARD (*Proc. Roy. Soc. [London]*, 79 (1907), No. 528, pp. 75-83).—It was found in experiments with small animals (cats) that the removal of three-fourths or more of the kidney weight was followed by a loss of appetite, wasting, and death within a few days or weeks. An increase output of nitrogen was not a constant occurrence and took place only when the animals had lost 22 per cent or more of their initial body weight.

"We conclude, therefore, that the kidneys have no direct influence upon nitrogenous metabolism, and that the increased output of nitrogen is simply the result of inanition, and is of the same nature as that observed in starving animals.

"We find that, after removal of a portion of one kidney, and also after subsequent removal of the opposite kidney, . . . [the animals experimented upon] are still able to pass a concentrated urine, and that the amount of the urine is not necessarily increased beyond the normal."

Concerning endogenous purin metabolism in man, V. O. SIVÉN (*Skand. Arch. Physiol.*, 18 (1906), No. 3-4, pp. 177-193).—From a discussion of original experimental data and the work of other investigators, the author concludes that purin excretion is not determined by muscular work. In a number of tests purin excretion diminished during sleep, but if the work of the kidneys was increased by a heavy meal before retiring the purin excretion was increased.

The results as a whole are discussed with reference to various theories which have been advanced with reference to purin metabolism.

Concerning phosphorus metabolism, E. KOCU (*St. Petersb. Med. Wchenschr.*, 1906, No. 36, pp. 400-402; *abs. in Zentbl. Gesam. Physiol. u. Path. Stoffwechsets, n. ser.*, 1 (1906), No. 23, p. 723).—The metabolism experiments reported furnish additional reasons for believing that the human body can not synthesize phosphorus compounds from protein-free phosphorus and inorganic phosphorus salts. It is perhaps possible, however, that inorganic phosphorus may be so utilized if organic phosphorus is excluded from the diet for a long time.

Equilibrium in metabolism, R. EHRSTRÖM (*Skand. Arch. Physiol.*, 18 (1906), No. 3-4, pp. 281-297, figs. 10).—A theoretical discussion of the possibility of obtaining equilibrium with respect to nitrogen and other constituents. The author believes that in general there is a temporary retention of an element and that excretion then proceeds step by step until equilibrium is reached, provided the amount supplied remains constant.

The excretion of total nitrogen and amino acids in fasting, T. BRUGSCH and R. HIRSCH (*Ztschr. Expt. Path. u. Ther.*, 3 (1906), No. 3, pp. 638-644).—The experiments, which were made with a woman who was a professional faster, led to the following conclusions:

The nitrogen excretion for a fasting woman was 6.4 grams on an average in the 16-day test reported, which was 25 per cent lower than in the case of a man. The excretion of amino acids in urine was not increased nor could free glycol be identified. Alanin is less thoroughly assimilated in fasting than under normal conditions. On the other hand, glycol and leucin are well assimilated. A retention of nitrogen may be induced during fasting if amino acids (leucin and alanin) are fed, even without the addition of carbohydrates. On the other hand, glycol is almost quantitatively converted into urea.

Acid formation in fasting, M. BÖNNIGER and L. MOHR (*Ztschr. Expt. Path. u. Ther.*, 3 (1906), No. 3, pp. 675-687).—The experimental data which were obtained with a fasting man led the authors to conclude that in all probability

oxybutyric acid is not formed in the body from leucin, or that at any rate if it be granted that theoretically leucin may yield isovaleric acid and the latter β -oxybutyric acid, such a process does not take place quantitatively in the body. By far the larger part of the acetone bodies excreted in the urine are derived from fat or fatty acids.

Third treatise on the effects of borax and boric acid on the human system, O. LIEBREICH (*London: J. & A. Churchill, 1906, pp. VIII+70, dms. 27*).—In this article, which is a translation from the German, the author gives a critical review of the experiments on the effects of borax made under the auspices of this Department (E. S. R., 16, p. 684) and disagrees with the general conclusions which were reached. Earlier work has been previously reported (E. S. R., 11, p. 962).

The occurrence and identification of soluble proteid in the feces of adults, H. SCHLÖSSMANN (*Ztschr. Klin. Med., 60 (1906), pp. 272-294; obs. in Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, n. ser., 1 (1906), No. 23, p. 723*).—According to the author, the proteids precipitated from feces extract by acetic acid consist very largely of a complicated mixture of nucleo-proteids, with mucin under some circumstances. When large amounts of nuclein are taken in the food the feces of healthy adults do not contain an increased amount of nucleo-proteids, but with children such an increase is noted. The author's investigations also include the pathology of the subject.

The phosphorus content of feces fat, J. H. LONG and W. A. JOHNSON (*Jour. Amer. Chem. Soc., 28 (1906), No. 10, pp. 1499-1503*).—Continuing earlier work (E. S. R., 18, p. 525) the phosphorus content of feces fat was studied. The fat content of 8 samples ranged from 8.6 per cent to 19.45 per cent on the dry-matter basis, and the P_2O_5 content of the fat from 0.2 per cent to 3.66 per cent.

"Extreme variations are shown in the percentage amounts of phosphoric acid recovered from the fat. As found before, these amounts are not increased by prolonged extraction."

As regards the source of the fats containing phosphorus the authors note that they may either represent unchanged substances from animal and vegetable foods or may represent products of metabolism within the body. The possibility of intestinal bacteria as a source of feces fat is also spoken of. The authors state that the investigations will be continued.

ANIMAL PRODUCTION.

Investigation of concentrated commercial feed stuffs as sold in Iowa, L. G. MICHAEL (*Iowa Sta. Bul. 86, pp. 52*).—A large number of commercial feeding stuffs collected in Iowa were analyzed, including blood meal, tankage, and similar products, cotton-seed meal, linseed meal, wheat shorts or standard middlings, flour middlings, mixed wheat feed, low grade or red dog flour, hominy feed, corn and oat chop, corn-and-cob meal, corn meal, mixed alfalfa feeds, oat shorts, oat bran, oat flour, oat middlings, germ oil meal, pressed cracklings, germ meal, and gluten feed.

The samples of blood meal received during the year, the author states, ran below the percentage of protein guaranteed by the manufacturers, and the same was true of tankage.

"Meat meal, also guaranteed to contain 60 per cent protein, has averaged 2.13 per cent below that standard, one sample dropping as low as 52.47 per cent. Both products, stated to be free from stomach contents, have been found to contain undigested oat hulls or hair. Even as high as 4.4 per cent of silica (the basic constituent of sand) has been found in some samples.

"Of 13 samples of cotton-seed meal examined, only one was found to be 'prime' or up to the standard of 41.2 per cent protein set by the Cotton-seed Crushers' Association. The samples below grade are heavily loaded with cotton-seed hulls, which brings the protein content from 1 to 3.5 per cent below guarantee.

"The by-products of the wheat flour industry vary greatly, according to the process of milling. The quality of the output from a number of mills also fluctuates according to the other grains that are being ground whose inferior offal is run into the wheat by-products. Fluctuations may be due to other adulterating materials at hand.

"The average of our analyses of the mill feeds sold in Iowa show that most of these products are below the standards of those manufacturers who stamp their guarantees on the sacks containing their feeds. . . .

"It is a common practice to run scourings, corn hulls and offal, oat hulls and the hulls of weed seeds into the bran. The ground weed seeds and screenings have been run into the shorts. The effect that this practice has on the quality of the bran and shorts depends upon the extent of the adulteration. At a few mills where such admixtures were made, it was possible to get samples of pure shorts and bran direct from the duster, and other samples from the packer at which the sacking of these by-products for shipment was made. In some instances the differences in protein content were as great as two per cent.

"At some mills a system of 'padding' is carried on; that is, a sack is partially filled with shorts and the balance of the sack filled with bran. The whole is then sold at shorts prices. Sweepings from the floor are also used as padding.

"Corn and oat chop is one of the most widely used feeds in the State and one that shows the greatest variety of composition. Many local millers complain that they can not buy corn and oats and grind them at a profit in competition with the brands of this product that are shipped in from outside their vicinity. These 'shipped-in' chops invariably contain oat hulls, light oats, ground cob, and milling offal that render it possible for them to be offered at a figure the local grinder can not touch."

Condimental stock foods and tonics, L. G. MICHAEL and H. O. BUCKMAN (*Iowa Sta. Bul.* 87, pp. 28, fig. 1).—A large number of foods and tonics were examined and found to consist of common drugs usually with the addition of some inexpensive material as a filler.

According to the authors, there is a great sameness in these compounds "claimed to work wonders with stock. Common salt, sulphur, charcoal, pepper, and gentian predominate among the useful drugs while the non-medicinal fenugreek is omnipresent. Any particular stock food may have certain other ingredients predominating; but variations from these few drugs are of little importance medicinally. There are only a few over two score of different substances that can be used in such mixtures."

The cost of manufacturing stock foods and tonics "does not warrant the manufacturer charging for them such exorbitant prices. The great bulk (one-half or more) is made up of some common feeding-stuff that markets at not more than \$1.50 per 100 lbs. (in one instance ground pine bark was used). About one-tenth is common salt and another one-tenth is charcoal. This leaves three-tenths to be made up of such simple drugs and remedies as anise, sulphur, ginger, red pepper, sassafras, and the like."

A formula for condition powders is quoted and modifications suggested which will enable the farmer to prepare a homemade stock food, if he wishes to use such material.

"A tablespoonful of such a mixture fed night and morning would not put his stock on the market in thirty days less time, neither would it double the flow of the milk of his dairy herd, nor would it prevent cholera in hogs, abortion in cattle, crop in chickens, nor glanders in horses. It is yet to be proved that any stock food or tonic will do this. The feeding of domestic animals is and always will be a matter of applied common sense and intelligence. But such a stock food would have the merit of being extremely inexpensive, besides having as much merit in other ways as any of its class."

From a summary of experiments on the effects of condimental stock foods on digestibility and related topics, it is evident, according to the authors, "that condimental stock foods and tonics, instead of producing the prodigious results claimed for them, have really little or no beneficial effects and may greatly increase the cost of beef, pork, and milk production."

The examination of cattle and poultry foods, J. B. LINDSEY (*Massachusetts Sta. Bul. 112, pp. 58*).—Under the provisions of the State feeding-stuff law analyses were made of a large number of samples of cotton-seed meal, linseed meal, gluten feed, dried distillers' grains, malt sprouts, dried brewers' grains, wheat middlings, wheat mixed feed, wheat feeds with admixtures, wheat bran, dairy feeds, molasses feeds, rye feeds, calf meal, corn meal, hominy meal, corn and oat feed, fortified starchy feeds, oat feed, miscellaneous starchy feeds, meat scraps, meat and bone meal, bone meal, granulated milk, poultry mash and meal, chick and scratching grains, and alfalfa and clover meals.

Some of the author's deductions follow: Most of the high-grade and medium cotton-seed meals were found to meet their protein guarantees and were of good color and taste. The new-process linseed meal contained rather less protein than was found in the two preceding years, though the price per ton was higher. The majority of the old process meals were of first grade. Four of the 19 samples were second quality, although the price asked for these was 29 cts. a ton in excess of that for first quality goods.

The author notes that many mills and large jobbers are placing a guarantee of composition upon their mill by-products. The importance of not running screenings, ground or unground, into these feeds is insisted upon. "It is believed that the addition of light oats, hulls, weed seeds, and the like will in the end work fully as much harm to the manufacturers as to the consumers."

The feeds classed as wheat feeds with admixtures were found to consist principally of bran and ground corn cobs in the proportion of about 3:1. "Our observations lead us to infer that these goods are frequently offered untagged, or sold for straight bran, the tags having been removed before delivery. We can not caution buyers too strongly to be on their guard against such deception."

As regards mixed dairy feeds, the author believes that while many of the proprietary mixtures found on sale should prove satisfactory as complete grain rations for dairy stock the dairyman can himself prepare as good or better rations for less money, and formulas for such mixed rations are given.

"The better grades of molasses feeds test rather higher in protein than formerly, are readily eaten, and can be safely fed as the entire grain ration if desired. At prevailing prices they do not furnish digestible matter as cheaply as it can be obtained from home-mixed rations, and as sources of digestible protein they are decidedly expensive. The writer can not from a standpoint of economy advocate these mixtures in place of those that can be made by the ordinary dairyman from cotton-seed meal, gluten feed, distillers' and brewers' dried grains, malt sprouts, flour middlings, corn and hominy meals."

Concerning the comparative value of red and white wheat for poultry feed,

the author states that one sort is as good as another, providing they are equally well developed. Alfalfa meal, he points out, is much superior to clover meal as a source of protein, and the tops of both plants are the best portion for poultry feeding. "Poultry men should grow their own clover, cutting and curing it when in the bud."

To facilitate the mixing of rations a table is given which shows the weight of a quart and the measure of a pound of a number of the more common proteid and starchy feeds.

The feed control in 1905-6, J. W. CARSON and G. S. FRAPS (*Texas Sta. Bul.* 90, pp. 74).—The text of the State feeding-stuff law is given and the results of examination of 1,626 samples are reported. These include corn chops, Kafir corn, corn bran, corn-and-cob meal, wheat bran, wheat shorts, wheat chops, cotton-seed meal, cotton-seed cake, cotton-seed scrum, cotton-seed feed (cold processed cotton-seed meal and hulls), mixed feeds, rice bran, rice polish, rice hulls, chicken feed (cracked rice), milo maize, ground oats, alfalfa meal, mixed poultry feed, blood meal, meat meal and similar goods, bone for poultry, and tankage. A number of samples were found lower than guaranteed, but in general the feeding stuffs on the market were satisfactory. "There have, of course, been cases in which inferior or adulterated feeding stuffs were sold, but for the most part the feeding stuffs have been of excellent quality."

Commercial feeding stuffs, J. L. HILLS and C. H. JONES (*Vermont Sta. Bul.* 124, pp. 8).—The following materials, cotton-seed meal and feed, linseed meal, gluten meal and feed, distillers' dried grains, molasses feed, hominy feed, oat feed, corn and oat feed, mixed feed and ground corn cobs, calf meal, meat and bone meal and poultry feed, were collected during the spring of 1906 and examined under the provisions of the State feeding-stuff law. Most of the materials entirely or very nearly met their guarantees.

As regards cotton-seed feeds, the authors call attention to the fact that their guaranteed protein content is practically one-half and their retail price five-sixths that of cotton-seed meal.

With the exception of 2 of the lower grade samples, all of the distillers' dried grains offered for sale were below the guarantee, as were also 4 of the 7 samples of molasses feeds. "These goods are relatively new on the Vermont feed markets, and are—speaking broadly—admixtures of waste molasses and sugars with sundry grain products and offals, or with beet pulp." With the exception of 1 brand, the 4 alfalfa feeds were equal to their guarantees. "These are also somewhat new in eastern markets. Cut or ground alfalfa hay—the whole plant in some cases, the more tender portions in others—form the basis, to which are sometimes added more or less of the approved forms of concentrates. The straight ground hay needs no guaranty."

"It should be clearly understood that guaranty maintenance, though desirable, is not the sole criterion by which a feed should be gaged. Many brands habitually contain less protein than their manufacturers claim for them, yet, notwithstanding, at ruling prices are far more economical and desirable purchases than are some feeds which regularly meet the low standards their makers set for them."

Commercial feeding stuffs, J. L. HILLS and C. H. JONES (*Vermont Sta. Bul.* 125, pp. 11-16).—In carrying out the State feed-inspection work, examinations were made of a number of samples of cotton-seed meal, linseed meal, gluten feeds, distillers' dried grains, brewers' dried grains, molasses feeds, alfalfa feeds, hominy feed, oat feeds, corn and oat feeds, wheat offals, and provenders, collected in November, 1906. With the exception of the cotton-seed meal and the

distillers' dried grains the materials examined met or very nearly met their guarantees.

"It should not, of course, be inferred, because the present low grade of cotton-seed meal is deplored and the continued shortage of distillers' dried grains is lamented, that consumers should turn the cold shoulder on these goods. Notwithstanding their failures to meet guarantees, they are far better purchases than are most if not all of the lower graded goods whose promised protein contents are maintained."

Licensed commercial feeding stuffs, 1906, F. W. WOLL and G. A. OLSON (*Wisconsin Sta. Bul. 142, pp. 54*).—Under the provisions of the State feeding-stuff law analyses were made of 248 samples of licensed and unlicensed feeds, including cotton-seed meal, linseed meal, gluten feeds, corn feeds and similar goods, mixed corn and oat feeds, commercial and proprietary dairy and horse feeds, malt sprouts, blood meal, meat meal and similar goods, mixed poultry feeds, molasses feeds, rye sprouts, wheat bran, wheat middlings, molasses beet pulp, oats, ground oats, clipped oats, corn meal, damaged wheat, wheat screenings, barley screenings, barley feed, barley hulls, wet brewers' grains, and buckwheat bran.

According to the authors, considerable improvement has taken place in recent years in the character of the concentrated feeds sold in Wisconsin. The number of deficiencies in guaranteed composition of licensed feeds was smaller this year, and fewer mixed feeds of inferior grade were offered for sale than in the past.

"Farmers and dealers can, therefore, feel that the feed market in our State is in a better condition in regard to the quality of the feed offered for sale, and reputable dealers have less to fear from dishonest competition than ever before.

"Several unsuccessful attempts were made to sell goods of inferior grade during the year. So far as we have been able to ascertain, no serious adulterations of feeding stuffs have, however, been practiced during the year in this State. The admixture of undesirable materials, like screenings to flour-mill feeds, barley hulls to malt sprouts, or manufacture of refuse-feeds from poorly-cleaned seed, as in the case of flour or oil mills, have been met with, but no dangerous adulterations have been found as, for instance, with rice hulls, which were found in last year's inspections."

Stock food [corn silage for horses] (*Natal Agr. Jour. and Min. Rec., 9 (1906), No. 12, pp. 1123-1128*).—The value of different forage crops for winter feeding is spoken of.

The statement is made that corn silage has been satisfactorily used at the Mooi River Remount Depot as feed for horses. The daily ration of horses running in paddocks consisted of 4 lbs. of chopped corn silage, 2 lbs. of alfalfa or forage, a few pounds of crushed corn, and an ounce of salt. "From the first they liked the ensilage and did remarkably well on it. Many horses not doing well before showed improvement. The droppings were of a particularly healthy nature. The stabled horses also had a few pounds mixed with other food—even those working—at their midday feed, and did well on it."

The calculated and determined nutrients of rations, J. A. HUMMEL (*Minnesota Sta. Bul. 99, pp. 121-132*).—In discussing feeding problems it is customary to calculate digestible nutrients by the aid of standard factors. Digestion experiments with steers, undertaken at the station and not yet reported, gave the opportunity of comparing calculated and determined results.

The ration fed consisted of 14 lbs. of ground grain made up of corn meal, bran, oats, and oil cake 4:3:2:1 with 10 lbs. of timothy hay and corn fodder

ad libitum (usually 5 lbs.) in addition. In determining the nutritive value of the ration it was found that the composition of the ground feed agreed so closely with the composition, as shown by analyses, of the separate ingredients that it was evident the grain mixture could be considered as one food material in making calculations and computations.

The following table shows the average results of the 6 digestion trials as determined and as calculated by means of digestion coefficients used with both determined and average values for the composition of feeding stuffs:

Comparison of determined and calculated amounts of nutrients digested from same ration.

Method followed.	Dry matter.	Protein.	Fat.	Total carbohydrates.	Ash.
	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>
Results obtained by digestion experiments	63.82	7.26	2.64	52.73	1.17
Results calculated from actual analyses of feeding stuffs and average digestion coefficients	64.66	7.54	3.06	50.47	1.36
Results calculated from average figures for composition of feeding stuffs and digestion coefficients	65.69	7.62	2.97	53.84

"It will be observed there is a reasonably close agreement between the actual digestible nutrients of this ration . . . and the calculated digestible nutrients. These results show that for all practical purposes the tables of digestible nutrients, as recorded in standard works on feeding compiled from the average composition of American feeding stuffs and average digestion coefficients, are sufficiently accurate for the general calculation of rations. The difference between the actual and calculated nutrients, as found in this investigation, in which 6 steers of widely different types were used, was small, amounting in 1 day to less than $\frac{1}{4}$ lb. of dry matter and less than $\frac{1}{16}$ lb. per day of protein.

"In the case of the individual steers the digestibility of the protein ranged from 59.32 to 66.64 per cent and the carbohydrates from 76.08 to 82.08 per cent. It is to be noted that in a mixed ration, such as used in this investigation, only about two-thirds of the dry matter . . . a little less than two-thirds of the protein, and about three-quarters of the fat and carbohydrates of the food consumed were digested and utilized by the body. These results show that under the condition of the experiment in which a mixed ration was used from one-third to one-fourth of the nutrients were voided as indigestible matter in the feces."

In the author's opinion the results of the experiments emphasize the desirability of using coarse fodder which supplies a maximum amount of protein.

The energy value of the urine was determined to secure data for calculating the available energy of the ration. The nitrogen in the urine and the balance of income and outgo of this constituent were also determined.

"In this investigation an average of 63.92 per cent of the total energy of the ration measured in calories or heat units was available to the body. In the daily ration the food supplies 47,875 calories and 30,600 calories were available to the body. While this is apparently a large loss, it is a more economical use of the fuel value than a steam engine where only about 15 per cent of the energy is available."

Composition and digestibility of emmer, J. A. HUMMEL (Minnesota Sta. Bul. 99, pp. 133-138).—The digestibility of whole and ground emmer fed with alfalfa hay and of alfalfa hay alone was determined in experiments with sheep. The average results follow:

Average digestibility of emmer and alfalfa hay—Experiments with sheep.

Kind of feed.	Dry matter.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Whole emmer and alfalfa hay.....	78.97	80.62	66.46	91.41	60.86	37.02
Ground emmer and alfalfa hay.....	81.33	82.62	77.55	88.74	70.49	51.36
Alfalfa hay.....	54.83	68.81	15.75	69.05	41.31	24.41
Emmer alone (calculated).....	93.99	86.73	92.38	96.56	83.60	53.23

As shown by the results, a ration of emmer and alfalfa hay when fed to sheep has a high digestibility, especially as regards protein and nitrogen-free extract. "There was a much more complete digestion of the ration of hay and grain than of the ration of hay alone." The results also show a high digestibility for emmer. "In localities where emmer can be grown successfully it will be found a valuable addition to the ration of growing or fattening cattle."

In connection with the digestion experiments the urine was collected and analyzed in order that the balance of income and outgo of nitrogen might be determined.

The heat-producing value of the crude fat of fodders and grains, H. SNYDER (Minnesota Sta. Bul. 99, pp. 139, 140).—In discussions of energy value ether extract is assumed to yield 9.5 calories per gram, which is the average value obtained when fat is burned in a bomb calorimeter. To ascertain whether this factor is accurate the heat of combustion of the ether extract of several kinds of coarse fodder was determined, the results being as follows: Corn fodder 8.047, corn silage 7.545, clover hay 8.036, and timothy hay 8.220 calories per gram.

"When the fats of wheat and barley were extracted and burned in the calorimeter they yielded 9.34 and 9.21 calories, respectively, indicating that with these cereals the ether extract has practically the same caloric value as pure fat."

It is evident that the figures for coarse fodder are from 11 to 20 per cent lower than the theoretical value and this difference is attributed to the presence of nonfatty material, such as chlorophyll, in the ether extract. To secure additional data regarding the proportion of such nonfatty bodies present determinations were made of the nitrogen content of ether extract and the following percentages were obtained: Clover hay 0.174, timothy hay 0.153, corn 0.062, oats 0.063, barley 0.047, and wheat 0.043 per cent.

"The nitrogenous matter in the ether extract from the grains was found to be much less than in that from the coarse fodders, as clover and timothy. In the case of wheat and barley, if all of the nitrogen of the ether extract is considered present as lecithin, there would be less than 8 per cent of this material.

"The heat of combustion of the ether extract of grains indicates that in the calculation of rations it may be regarded as having the same energy value as fat; in coarse fodders, however, the ether extract has an energy value of 11 to 20 per cent less than fat. . . .

"While the chlorophyll reduces the heat of combustion of the ether extract, there are compensating factors; its presence in the fodder is a desirable characteristic, for the color of the fodder is due to chlorophyll and is an index of quality. Feeders justly give preference to well-cured fodders of good color."

The digestibility of rye feed meal, O. KELLNER ET AL. (*Landw. Vers. Stat.*, 65 (1907), No. 5-6, pp. 466-470).—In digestion experiments with sheep it was found that rye feed meal on an average had the following coefficients of digestibility: Dry matter, 92.7; protein, 75.9, and nitrogen-free extract, 96.8 per cent.

The facility of digestion of foods a factor in feeding, C. L. BEACH (*Connecticut Storrs Sta. Bul.* 43, pp. 23).—A series of tests is reported in which corn meal and mixed hay in turn were fed as a maintenance ration to 2 dry, farrow cows. The results of tests with milch cows, pigs, and calves are also quoted and discussed for purposes of comparison.

On an average 6.25 lbs. of corn meal containing 4.5 lbs. digestible nutrients was required for maintenance by the farrow cows as compared with 13.15 lbs. of hay containing 7.1 lbs. of digestible nutrients; that is, on an average 57 per cent more digestible nutrients was required for maintenance when derived from hay than from corn meal. "Less digestible nutrients from corn meal, therefore, were required for maintenance than from hay, because less energy of the feed was used in the work of digestion and assimilation." "An increase in the proportion of grain to roughage in a ration for milch cows [in tests which were quoted] tends to facilitate digestion, and is followed by increased production."

A similar explanation will account for the more rapid gain in the case of the pigs and calves fed the more easily digestible rations in the tests summarized. In general, according to the author, "the value of a feed depends upon its composition, digestibility, and ease or facility of digestion. The first two factors are considered in the formulation of rations. The third factor has only recently been recognized, and little definite knowledge in regard to it is at hand. In a general way it is recognized that milk is more easily digested than meal, concentrates than roughage, early than late cut hay, silage than corn stover, oat than rye straw. A pound of digestible matter, therefore, should be more valuable in the former than in the latter."

Investigations in the use of the bomb calorimeter, J. A. FRIES (*U. S. Dept. Agr., Bur. Anim. Indus. Bul.* 94, pp. 39).—The results of investigations like those carried on with the respiration calorimeter at the Pennsylvania Experiment Station in cooperation with the Bureau of Animal Industry depend for their value in large measure upon accurate determinations of the heats of combustion of feed, urine, and feces. Critical studies were therefore undertaken of the determination of such values and the factors which affect the accuracy of results and related questions.

The bomb calorimeter used is briefly described and the methods of operating it are outlined. Among the factors affecting accuracy of results which were investigated were the quality of the oxygen, the formation of nitric acid in the bomb during combustion, the oxidation of combined nitrogen to nitric acid, and incomplete combustion.

The experimental and analytical data reported led to the following conclusions: "There are many possibilities for error in the work with the bomb calorimeter. Undoubtedly many investigators in the past have worked with impure oxygen and never questioned its purity. In the light of our present experience it is questionable whether Stohmann himself, by the use of a heated copper tube, could have removed the last traces of combustible gases from his oxygen. The disappearance of nitric acid formed and its relation to the ash has not been taken into consideration, and it is only within a couple of

years that the thermometer lag has come to be applied in the calculations of the results.

"These overlooked or at times unknown difficulties . . . may be the cause of some of the disagreements of results as experienced by different investigators."

The author believes that "much work is yet needed in the different lines indicated before the method for determinations of heat of combustion by means of the bomb calorimeter can be called perfect."

Animal breeding in Europe, W. J. KENNEDY (*Amer. Breeders' Assoc. Proc.*, 2 (1906), pp. 135-149).—The leading features which underlie the successful animal breeding in Europe, according to the author, are "a genuine liking for good animals, a keen judgment of animal form, a clear cut and well-defined aim or purpose, permanency of work, good judgment and care in the selection of sires, impartiality toward fads and fashions, the beneficial influences of government aid, the favorable climatic influences in certain districts, and the pecuniary advantages accruing from live-stock farming."

American work in breeding plants and animals, W. M. HAYS (*Amer. Breeders' Assoc. Proc.*, 2 (1906), pp. 155-167).—As the author points out, the United States as a whole and the individual States are giving very broad recognition to breeding interests. The lines of work followed are concerned with the introduction of plants and animals, breeding experiments carried on by private individuals, cooperative work between public and private agencies, educational work in breeding, and research work in heredity and breeding. In all these lines except the second the National Government and the States take a prominent part.

Carcasses of beef and live-weight prices, W. DINSMORE (*Breeder's Gaz.*, 51 (1907), No. 8, p. 409, figs. 2).—The commercial cuts into which a beef carcass is divided are illustrated and the proportion of high-priced and low-priced cuts discussed with reference to practical feeding.

"For years there has been, and there is now, a keen demand for cattle that will cut out heavy loin and rib cuts with a minimum per cent of those cuts that are less in demand. The heavy muscles on the back and loin, which give thickness to these parts, can not be developed by exercise, for they are used only in bending the back down or to one side; and if they could be so developed it would not be desirable, as it would but result in coarsening the fiber, thereby making them less tender. Feeding within practical reasonable limits has but little influence on the per cent of lean meat, and the only way in which we can increase the thickness of flesh element on these most-desired parts is by the selection of thick-fleshed sires and dams, by the utilization of every favorable variation in this direction."

Skim milk as a feeding stuff for calves, A. PROCCHI (*Ann. Ist. Agr. [Milan]*, 6 (1901-5), pp. 123-189, figs. 2).—Experimental studies are reported and data summarized regarding the feeding value for calves of skim milk alone and supplemented by different materials, including among others rice, ground malt, corn meal, linseed oil, peanut oil, sesame oil, oleomargarine, dried blood, eggs, and commercial calf feeds. Gain was most cheaply made with skim milk supplemented by oleomargarine, and was most expensive with whole milk.

A bibliography of skim milk as a feeding stuff is an important addition to the report. A briefer account of the experiment has already appeared (*E. S. R.*, 17, p. 894).

The amount and fat content of the milk taken by sucking calves, SCHILLER-TIETZ (*Vrtljschr. Baycr. Landw. Rat.*, 11 (1906), No. 3, pp. 679-687).—

From a summary of data the author concludes that the desire for milk with a high fat content expresses a physiological demand.

Fattening range lambs, B. E. CARMICHAEL (*Ohio Sta. Bul.* 179, pp. 68-88, figs. 4).—The relative value of cotton-seed meal, linseed meal, and a commercial stock feed as supplements to corn was studied with 4 lots of 40 wether lambs each, the test covering 103 days. In every case the grain ration was supplemented by clover, blue-grass, and alfalfa hay.

The daily gain on the corn ration was 0.298 lb. per head and on corn supplemented by other concentrated feed it ranged from 0.302 lb. on linseed meal to 0.312 lb. on a commercial stock feed. The cost of a pound of gain on the corn ration was 4.91 cts., on the ration with a commercial stock feed 4.80 cts., and on cotton-seed meal and linseed meal 5.14 and 5.31 cts., respectively. One of the lambs fed the commercial stock feed died during the test. When the lots were slaughtered and dressed the shrinkage ranged from 50.9 per cent with the cotton-seed meal lot to 53.5 per cent with the corn lot.

The manure from the 4 lots was collected and its value estimated, that obtained from the lots fed cotton-seed and linseed meal being the most valuable. "The extra cost of the rations, however, more than equaled the increased value of the manure."

As pointed out by the author, the lot fed the commercial stock feed made slightly greater gains at a lower cost than the other lots, and also shrank less in shipping and yielded a higher percentage of dressed weight than any of the lots except that fed the corn ration without additional concentrated feed. The author notes, however, that the differences in gains between the 3 lots receiving concentrated feed in addition to corn were so small that it can not be said that any of the rations possessed a decided superiority over the others. "It would not be surprising if the same rations should give opposite results in future trials, and it is safe for us to consider that the rations tested are of practically equal value pound per pound for use in lamb feeding under the conditions of this test."

Crossbred lambs, G. M. McKEOWN (*Agr. Gaz. N. S. Wales*, 18 (1907), No. 2, pp. 156-158, figs. 5).—As regards the number of lambs born, average weight, etc., the best results were obtained with a Lincoln-Merino cross in lamb-breeding experiments at the Wagga Experimental Farm.

Swine, J. J. MORTON (*Orange River Colony Dept. Agr., Ann. Rpt.*, 2 (1905-6), pp. 54-62, pls. 2).—Brief statements are made regarding the pigs kept at the Tweespruit Experimental Farm and a feeding test undertaken with reference to the production of bacon hogs is reported.

Four lots containing 4 large Yorkshire pigs each were used, and the rations consisted of separator skim milk and maize meal, buttermilk and maize meal, and skim milk and Kafir corn meal in each case 3:1, and wheat middlings (sharps) and maize meal 1:2 mixed to a slop with water. In the 49 days of the test the gain ranged from 66.25 lbs. per head on the wheat middlings and maize meal to 98 lbs. on skim milk and maize meal. The gain was most cheaply made on the last-mentioned ration and was most expensive on the Kafir corn ration. The shrinkage in dressing averaged 20 per cent of the live weight, and when marketed "the meat gave entire satisfaction as to quality and flavor" and was regarded as superior to imported bacon.

In the author's opinion so good results would not have been obtained with ordinary Kafir or unimproved pigs, "but even at a much lower rate of increase they afford a profitable means of disposal for a portion of the mealie crop."

Fattening pigs, M. RASQUIN (*Jour. Soc. Agr. Brabant et Hainaut.*, 52 (1907), No. 7, pp. 178, 179).—From a summary of data the author concludes that sugar

in all forms is well worth the attention of pig feeders, as it is an important feeding stuff.

Breeding American carriage horses, G. M. ROMMEL (*Amer. Breeders' Assoc. Proc.*, 2 (1906), pp. 177-184).—The cooperative investigations undertaken under the auspices of the Bureau of Animal Industry of this Department are outlined and discussed.

Poultry observations, C. K. GRAHAM (*Connecticut Storrs Sta. Bul.* 44, pp. 25-35, figs. 3).—The author studied the causes of high mortality so often noted with young chicks and the effects of substituting snow for drinking water with laying hens and chickens.

When newly hatched chicks were given food mixtures containing salt, sawdust, sugar, and musty grains in addition to the usual feeds, it was noted that the salt and sugar were selected first, perhaps owing to their bright appearance, and that musty grain or sawdust was as readily eaten as more suitable food. Chicks 8 or 9 days old showed more discrimination in the selection of the materials eaten, and therefore the author believes that the death of very young chicks is often caused by eating musty grain accidentally present in their other feed, although as shown by the observations reported "there is no doubt that faulty brooders, chills, overheating, improper ventilation, and lack of vitality in the parent stock should all receive proper credit for their share."

When snow was supplied instead of water to laying hens it was noted that old hens were more affected than young birds. In one of the tests the egg production of the old hens was smaller "on the days when snow was on the ground, and also considerably less when the ground was frozen; that is, on the cold days when water was not accessible. These conditions do not seem to have affected the younger birds, and they show an increase in eggs immediately after each snow storm, gradually dropping back as the snow disappears."

In another test made under similar conditions, except that the houses were located in a drier locality "the cold weather did not affect the egg production, but there was a noticeable increase in the amount of grain eaten during the cold weeks, when comparison is made with the very mild ones. This, however, may have been caused by the birds foraging more during the milder periods. These birds did not appear to mind the cold and there was not the slightest sign of frosted combs among them, nor were there any colds."

Data regarding other lots are briefly reported and in general it was noted that "when snow was given there was generally an extra amount of feed required, although the increase in eggs more than paid for it." "The time saved by using snow and dry mash amounted to nearly half that required in tending the fowls."

When cold water was compared with warm water the average egg yield was much the same, though slightly in favor of the latter.

"Snow was given to young chicks, but the results were disastrous; although chicks that were reared in outdoor brooders were let run on the snow crust during bright days when 3 weeks old or over and no serious results followed."

Poultry raising, J. G. HALPIN (*Michigan Sta. Bul.* 245, pp. 113-136, figs. 3).—The station has begun extended studies of various problems connected with poultry feeding and in this bulletin an account is given of the equipment and plans.

To meet the present demands for information on various points connected with poultry raising, a general summary of data on the subject has been prepared, including such topics as food and exercise, selection and mating, incubation, brooding, handling young stock, feeding, care and management of pullets during fall and winter, construction of poultry buildings, and some diseases of chicks.

Poultry, H. RABY (*Orange River Colony Dept. Agr., Ann. Rpt., 2 (1905-6)*, pp. 87-97, fig. 1).—Information is summarized regarding the poultry kept, the number of eggs produced, and the methods of raising and feeding chickens followed at the Grootvlei Experimental Farm.

In the author's opinion the most satisfactory method of feeding poultry for market under local conditions is to confine them in crates in a partially darkened fattening shed, which should give protection from wind and be well ventilated. During the first 3 days of the confinement the fowls should be fed sparingly, but afterwards given all they will eat 3 times daily and be supplied with an abundance of grit and water. About 16 days are required to feed the birds for market.

In a feeding test in which 122 birds were fed under these conditions from 7 to 24 days the average weight at the beginning was 3 lbs. 9 oz. and the average gain 1 lb. The calculated profit per head was 27 cts. "It was found during the course of the feeding period that the rate of gain became less after the second week and ceased to be profitable when 16 or 17 days had passed. Fifteen days on full feed appears to be the most suitable time for fattening." The feed consisted of maize meal, bran, and ground oats with the coarse husk sifted out 2:2:1 made into a stiff batter with water. "Skim milk should be used in preference to water when it is available."

Portable houses for poultry are considered desirable and the construction of such a house is briefly described.

Success in egg culture, H. V. HAWKINS (*Jour. Dept. Agr. Victoria, 5 (1907)*, No. 1, pp. 11, 12).—A brief account of a successful attempt to keep ducks for egg production. The total number of eggs produced by 390 ducks and 50 fowls in 6 months was 34,860.

Report on small poultry stations, D. F. LAURIE (*Jour. Dept. Agr. So. Aust., 10 (1907)*, No. 7, pp. 431-436).—A brief note on the aims, present condition, and work accomplished at the six small demonstration poultry plants recently established by the South Australia Department of Agriculture. Five of these stations are for the study of egg production and one for the production of table birds.

The sale of undrawn and cold storage poultry, E. M. ECKARD (*Chicago Clin., 20 (1907)*, No. 1, pp. 5-8).—The author has studied the condition and appearance of chickens when kept for 6 months in cold storage, and also the bacteria of the intestines and related questions.

"Bacteria normally inhabiting the intestinal tract are not destroyed by cold storage, neither are the eggs of the blowfly. These bacteria and maggots develop during the rise of temperature that takes place after removal from cold storage before they are killed by heat. The bacteria pass through the walls of the intestines into the peritoneal cavity and liver, while the poisons formed by the bacteria are more penetrative and pass deeper into the muscles. That these products of bacteria, called ptomaines, are poisonous is shown by their effect upon the guinea pig even in small amounts. These poisons are not destroyed by heat as are the bacteria and produce the looseness of the bowels after eating this class of food. In large amounts this poison results in vomiting, severe intestinal pain, collapse, and even death. This is known as ptomaine poisoning, and for it there is no known antidote."

The author's report is preceded by a general discussion of cold-storage products and especially of cold-storage poultry, in which it is pointed out that when chickens are kept undrawn for a long period the fluid portion of the intestinal contents may pass into the adjacent flesh to the injury of the quality

of the product. With freshly killed poultry the matter is very largely a question of the purchase of something which is valueless, as the intestines and their contents may ordinarily be soon withdrawn.

As regards cold-storage products in general, "there may be some question as to the deleterious effect of prolonged storage. It may be reasonably contended, as it has been contended, that these products are fit for human consumption so long as they are palatable. However, the skillfulness of purveyors of foods in preventing apparent decomposition by the use of antiseptics and deodorants impresses us that we can not rely upon the senses in determining the poisonous character of foods."

Composition of body fluids in marine animals, S. BAGLIONI (*Beitr. Chem. Physiol. u. Path.*, 9 (1906), pp. 50-66; *abs. in Jour. Chem. Soc. [London]*, 90 (1906), No. 530, II, p. 869).—Chemical studies of the body fluids of fish and other marine animals are reported. The body fluids of various marine invertebrates contain very variable amounts of protein. In higher mollusks and arthropods the amount of protein is important and the quantity of extractive nitrogen is small, being less than one-tenth of 1 per cent.

DAIRY FARMING—DAIRYING.

A profitable tenant dairy farm, L. CARRIER (*U. S. Dept. Agr., Farmers' Bul.* 280, pp. 16, figs. 3).—This is a description of a dairy farm of 120 acres, located in southern Michigan, from which both owner and tenant received adequate compensation for their investment and services. Particular attention was paid to increasing the fertility of the soil.

Comparison of concentrates for dairy cows, J. R. FAIN (*Virginia Sta. Rpt.* 1906, pp. 12-14).—Cotton-seed meal and corn-and-cob meal were mixed in such proportion (139.5 to 360.5) as to contain the same amount of digestible protein as wheat bran. The mixed feed and the bran were fed to 2 lots of 8 cows each for 117 days. There was very little difference (\$1.45) in the cost of feeding the 2 groups of animals for the time mentioned. The 8 cows fed bran lost 224 lbs. in weight, while those fed the mixed feed gained 90 lbs. The difference in the production of the 2 groups, amounting to 1,262 lbs. of milk and 81.6 lbs. of butter, was also in favor of the mixed feed. The author, therefore, concludes that just as good or better results can be secured from a mixture of corn-and-cob meal and cotton-seed meal as from wheat bran.

Potatoes as a feed for dairy cows, H. ISAACHSEN (*Ber. Norges Landbr. Høiskoles Virks.*, 1905-6, pp. 183-202).—A study was made of the relative value of potatoes and turnips for dairy cows. Eight cows separated into 2 lots were included in the experiment, which lasted from March 15 to May 25. The cows received from 1.8 to 2.7 kg. of dry matter in the roots or tubers per head daily, from 8.8 to 13.2 kg. of potatoes and 20 to 30 kg. of turnips being fed.

The cows did not yield quite so much milk on potatoes as on turnips. The potatoes did not injure the health or general condition of the cows, nor was any deleterious influence to be noticed as regards the fat content of the milk, the time of churning, the water content of the butter, or the chemical properties of the butter fat, as shown by the iodine number, Reichert, and Köttstorfer numbers. The flavor of the butter produced on the potato ration was possibly not quite equal to that of the butter produced on the turnip ration. Practical experiences as to the value of potatoes for cows were also ascertained and are summarized in the paper.—E. W. WOLL.

Reindeer moss as a feed for milch cows, H. ISAACHSEN (*Ber. Norges Landbr. Høiskoles Virks., 1905-6, pp. 202-216*).—An experiment conducted by the author with 8 cows for a period of over 4 months showed that 1 kg. of moss can replace 3 kg. of turnips in rations for cows without producing any deleterious effect on the milk yield, the weight of the cows, or the fat content of the milk. The average of 5 analyses of reindeer moss was as follows: Water, 48.3 per cent; fat, 0.96 per cent; protein, 1.17 per cent; nitrogen-free extract, 18.1 per cent; fiber, 20.8 per cent; starch value per 100 kg. (Kellner), 18 kg.; digestible protein (artificial digestion), 65 per cent.—F. W. WOLL.

Department of dairying, W. D. SAUNDERS (*Virginia Sta. Rpt. 1906, pp. 47-49*).—Brief notes are given on the work of this department of the station during the year and official 7-day tests of 4 Holstein-Friesian cows are reported.

Investigations on the influence upon milk production of the nonproteid nitrogenous compounds of feeding stuffs, A. MORGEN, C. BEGER, and F. WESTHAUSSER (*Landw. Vers. Stat., 65 (1907), No. 5-6, pp. 413-440*).—This experiment is in continuation of the series of investigations previously noted (E. S. R., 18, p. 171).

During the first and fourth periods of 11 days each a goat and a sheep were fed a normal proteid ration. During the second period the proteids were in part replaced by amids prepared by extracting young plants with boiling water and evaporating the fluid extract to the consistency of a sirup. During the third period the amids were replaced by carbohydrates. The most favorable influence upon milk production was exerted by the proteid ration. The amids were not equal in value to the proteids, but were much superior to the carbohydrates. Further experiments along this line are planned.

On the influence of the feed on the creaming quality of the milk, J. SÄLAND (*Ber. Norges Landbr. Høiskoles Virks., 1905-6, pp. 220-226*).—The experiments conducted by the author indicate that milk produced on rations made up mainly of hay and straw, with only small amounts of concentrated feeds, gives considerable more cream than that produced by cows fed richer rations, consisting of roots and only a little hay and straw, with a good deal of concentrated feeds. This appears to be due to other properties in the milk than its fat content, such as a change in viscosity, differences in the condition of the casein, etc., which may be traced to the character of the feed eaten by the cows.—F. W. WOLL.

An investigation into the quality of milk produced by different breeds of cows at Eisenburg Agricultural College, G. N. BLACKSHAW (*Agr. Jour. Cape Good Hope, 30 (1907), No. 3, pp. 354-358*).—Determinations were made of the fat content of the milk of the Friesland, Jersey, Shorthorn, and Ayrshire breeds, and also of native Cape of Good Hope cows from October, 1906, to February, 1907. The milkings were made at 6:30 a. m. and 4:30 p. m. The milk of the Friesland, Shorthorn, and Cape cows averaged less than 3 per cent of fat in the morning. The milk of individual cows very frequently fell below the standard of 3 per cent of fat. The author, therefore, believes that much evidence should be secured before the British standard of 3 per cent of fat and 8.5 per cent of solids-not-fat should be accepted in Cape Colony.

The properties and value of the milk of sheep, A. BURR (*Molk. Ztg., 21 (1907), No. 14, pp. 359-361*).—This discussion of the composition and value of sheep's milk includes a compilation of analytical data.

On the milk production of Karakul sheep, L. ADAMETZ (*Österr. Molk. Ztg., 14 (1907), Nos. 6, pp. 73-75; 7, pp. 87-89, figs. 5*).—This Asiatic breed of sheep, known also as Persian sheep, is described and its importance for middle Europe

is pointed out. The milk of this breed has been used in the manufacture of Brinsen cheese in the Carpathian Mountains.

A classification of dairy bacteria, H. W. COXN, W. M. ESTEN, and W. A. STOCKING (*Connecticut Storrs Sta. Rpt.*, 1906, pp. 91-203).—This is a revision of a preliminary classification published in the report of the station for 1899 (E. S. R., 12, p. 1083). The revision has been based upon extended laboratory investigations in which species collected from various parts of the world, including Canada, Germany, Switzerland, and Italy, have been studied.

Several forms previously described are not included, while a large number of new species are described. The technical descriptions of the different species include nearly all of the characteristics usually adopted for the general description of bacteria. The formation of indol and the reduction of nitrates have, however, been omitted as not having much significance in relation to dairy problems, with which the authors have been particularly concerned. In all about 160 types are described, with few exceptions all actual cultures obtained from dairy materials. In addition to the detailed descriptions of the different bacteria analytical keys and tables covering all types are given.

Classification of lactic-acid bacteria, F. LÖHNIS (*Centbl. Bakt. [etc.]*, 2. *Abl.*, 18 (1907), No. 4-6, pp. 97-149).—This is a review of the literature of this subject, with an appended bibliography.

The kinds of lactic acid produced by lactic-acid bacteria, P. G. HEINEMANN (*Jour. Biol. Chem.*, 2 (1907), No. 6, pp. 603-612).—The author has determined the kind of lactic acid produced by various species and strains of lactic-acid bacteria in pure and mixed cultures, and has also studied the influence of the purity of the milk and the temperature and length of time of fermentation upon the production of the different lactic acids.

The streptococci (*Streptococcus pyogenes*, *S. lacticus*, and *Micrococcus lanceolatus*) produced d-lactic acid and the bacilli (*Bacillus acidi lactici*, *B. aerogenes*, and *B. coli*) l-acid. This is offered as an additional proof of the similarity or identity of *S. lacticus* and *S. pyogenes* and also of *B. acidi lactici* and *B. aerogenes* (E. S. R., 18, p. 672). Milk soured naturally at room temperatures contained chiefly d-acid and at 37° chiefly r-acid, l-acid becoming in excess after varying lengths of time. The lactic acid produced in spontaneous souring varied, therefore, with the relative numbers of streptococci and bacilli, with the temperature, and with the duration of the fermentation. The purer the milk the longer the d-acid remained in excess. The presence of d-acid is, therefore, an indication of desirable dairy conditions. Racemic lactic acid, according to the author, is the result of the formation of pure d-acid and pure l-acid by at least 2 different species of micro-organisms.

Acid and rennet-producing bacteria in relation to the hygiene of milking, C. GORINI (*Rev. Gén. Lait*, 6 (1907), No. 8, pp. 179-185).—The author has demonstrated the presence of bacteria capable of producing both acid and rennet in the galactophorous ducts in both normal and abnormal conditions. The significance of these organisms is discussed and the importance of rejecting the foremilk and of thorough milking is emphasized.

On a new micro-organism of ropy milk (*Bacillus surgeri*), P. DORNIC and P. DAIRE (*Bul. Mens. Off. Renseign. Agr. [Paris]*, 6 (1907), No. 2, pp. 146-149).—The new bacillus studied and described by the authors was isolated from the serum obtained in the manufacture of casein. The bacillus is nonmotile, varies in length from 2 to 135 μ , and retains the stain by Gram's method. Spores have not been observed, though the organism resists a temperature of 85° C. for 45 minutes. A marked characteristic of the organism is the rapid produc-

tion of acid in cultures. The viscid substance soluble in water from which it is precipitated by alcohol reduces Fehling's solution.

The relative opsonic power of the mother's blood serum and milk, E. TURTON and R. APPLETON (*Brit. Med. Jour.*, 1907, No. 2415, p. 865).—Cow's blood serum was found to have about one-half the opsonic power of human blood, the average for 3 cows being 0.49 for the tubercle bacillus and 0.71 for the *Staphylococcus pyogenes aureus*. The index of the milk of the 3 cows averaged about 0.25 for the tubercle bacillus and 0.18 for the staphylococcus. Ordinary market milk averaged 0.20 and 0.05, respectively, for the same organisms.

Milk and milk adulteration, A. J. J. VANDEVELDE (*Ghent: J. Siffer*, 1907, pp. 110).—This manual is written with the view of defining public responsibility in the matter of the production, handling, and sale of milk. Chapters are devoted to the composition of milk, causes of changes in the composition and properties of milk, nutritive value of milk, adulteration of milk, legislation relating to milk control in different countries, methods of analysis, the decomposition of milk, milk preservation, milk products, and a general discussion of the public duties and responsibilities of the producer, dealer, and consumer of milk, and also of public officials concerned.

Clean milk for New York City (*Rpt. N. Y. Milk Conf.*, 1906, pp. 86).—In a conference held in New York City in November, 1906, the following subjects relating primarily to the milk supply of New York City were discussed by numerous speakers: Skim milk, pasteurization, infants' milk depots, model milk shops, inspection, legislation, and education.

The Danish pasteurization law (*Mælkeritid.*, 19 (1906), No. 46, pp. 967-979; *Ugeskr. Lædm.*, 53 (1906), pp. 754, 755).—This is a report of the chemical department of the Copenhagen Experiment Station on the operations of the Danish law of February 5, 1904, directing the pasteurization of skim milk, buttermilk, and cream in creameries for the combating of tuberculosis in cattle and swine.

The report shows that 1,328 creameries were inspected during the year 1905-6 in accordance with the provisions of the law. Of the 6,801 samples of skim milk and 6,830 of buttermilk and cream taken by the authorities, 225, or 3.3 per cent, of the former, and 168, or 2.4 per cent, of the latter were found insufficiently heated. One thousand and seven creameries conformed to the provisions of the law, while 262 violated it through negligence or lack of care in the pasteurization of their products and paid the penalties imposed upon them by the courts.—F. W. WOLL.

The sterilization of milk; its sanitary necessity and practical realization, A. VOIGT (*Thesis, Leipzig*, 1906; *abs. in Hyg. Viande et Lait*, 1 (1907), No. 3, p. 122).

The sanitary control of the production and sale of milk in the United States, L. PANISSET (*Hyg. Viande et Lait*, 1 (1907), No. 2, pp. 49-53).—A brief general discussion of this subject.

The preservation of milk from a physiological standpoint, G. WULFF (*Abs. in Chem. Zentbl.*, 1 (1907), No. 13, p. 981).—The author concludes from the results of his investigations that hydrogen peroxid added to milk not only exerts a bactericidal action, but also produces certain changes in the proteids of the milk.

The volatile water-soluble fatty acids in East Prussian dairy butter, RUSCHE (*Molk. Ztg.*, 21 (1907), Nos. 11, pp. 269, 270; 12, pp. 299-302).—The results of the examination of butter from 7 dairies in East Prussia from August, 1905, to July, 1906, are reported. The cows were fed in the stable dur-

ing the months from November to April and pastured during the remainder of the year. The results are summarized in the following table:

The Reichert-Meißl and saponification numbers of East Prussian butter.

	August, September, October.	November, December, January.	February, March, April.	May, June, July.	Entire year.
Reichert-Meißl number:					
Average.....	25.59	29.67	29.55	28.18	28.25
Maximum.....	27.86	32.56	31.49	30.30	32.56
Minimum.....	23.43	27.11	27.90	25.51	23.43
Saponification number:					
Average.....	223.3	229.1	228.7	226.4	226.9
Maximum.....	227.3	235.5	234.7	231.2	235.5
Minimum.....	219.8	225.2	225.7	222.6	219.8

Danish butter exports, 1905-6, B. BÜGGILD (*Tidsskr. Landökonom., 1906, pp. 593-608*).—The total exports of butter for the year ended September 30, 1906, were 181,840,363 Danish pounds (200,024,399 lbs. avoirdupois), of which amount 168,146,990 lbs. went to Great Britain and 12,411,165 lbs. to Germany. The net exports were 144.8 million pounds, against 150.9 millions the preceding year. The average quotation for the year by the Wholesale Dealers' Association was 97.7 öre (1 öre= $\frac{1}{4}$ cent), against 94.0 öre for 1904-5. No previous year has witnessed a larger income from the Danish butter exports than that of 1905-6, viz. over 161,000,000 kroner (\$44,000,000).—F. W. WOLL.

Dr. Edward von Freudenreich, O. JENSEN (*Milchw. Zentbl., 3 (1907), No. 3, pp. 119-128; Rev. Gén. Lait, 6 (1907), No. 7, pp. 154-160*).—This is a review of the investigations of von Freudenreich, the most important of which related to the ripening of cheese. Appended to the article in the *Zentralblatt* is a complete list of the works of von Freudenreich.

VETERINARY MEDICINE.

Proceedings of the American Veterinary Medical Association (*Proc. Amer. Vet. Med. Assoc., 43 (1906), pp. 432, pls. 10*).—The papers presented at the forty-third annual convention of the association in New Haven, Connecticut, August 21-24, 1906, have been previously noted (*E. S. R., 18, pp. 98-100*). A number of papers were read by title only and brief mention of them is made herewith.

The recent Federal meat-inspection legislation was explained by J. R. Mohler (pp. 142-144) with reference to its effectiveness and enforcement. The method of controlling rinderpest in the Philippines was described by A. S. Shealy (pp. 313-319). In obtaining serum, Chinese cattle are used chiefly, and all these animals are rendered immune before their serum is used. It has not been determined how long the serum will retain its vitality, but the results obtained from its use are highly satisfactory.

A menace to the goat and sheep industry in New England by strongylosis was set forth by J. B. Paige (pp. 320-344). The methods commonly recommended for ridding pastures of these parasitic worms are not always effective. Drainage of the land proved unsuccessful in a number of instances. Burning over the pastures in spring or fall is effective, but causes a loss of forage and in many locations is dangerous. It is suggested that burning might be confined to a narrow strip of land surrounding streams or swamps. A better system of feed-

ing is also urged. Pictou cattle disease was discussed by W. H. Pethick (pp. 345-349), who has found that this form of hepatic cirrhosis is due solely to eating *Senecio jacobina*. The symptoms of the disease are described from a number of cases observed by the author.

A paper was presented by D. A. Hughes on the veterinarian as a business man (pp. 350-365). It was urged that while considerable business acumen is necessary to the success of the veterinarian the mere accumulation of money should not be his whole purpose in life, since considerable of the energy of the veterinarian must be expended in developing a knowledge of a rational control of animal diseases by stock growers.

Annual report of the superintendent, civil veterinary department, W. D. GUNN (*Rpt. Dept. Agr. Madras, 1905-6, pp. 48-63*).—The work of the veterinary college of the department of agriculture is reported to have been very successful during the year. The prevalence of foot-and-mouth disease was less pronounced than in former years. Rinderpest occurred to a serious extent, but the outbreaks were soon brought under fairly good control. Brief notes are also given on veterinary hospitals, pony breeding, and cattle fairs.

Report of the veterinary division, A. GRIST (*Orange River Colony Dept. Agr., Ann. Rpt., 2 (1905-6), pp. 107-128*).—Quarantine is still maintained in the Orange River Colony against cattle coming from the Transvaal on account of the east coast fever. Tables are given showing the prevalence of contagious diseases during the years under report and notes are presented on the status of foot-and-mouth disease, hog cholera, pleuro-pneumonia, blackleg, and various noncontagious diseases. The number of cases of mange has increased considerably during the past few years. Numerous cases of plant poisoning are reported and an account is given of geel-dikkop, the nature of which is not yet understood.

Report of the chief stock inspector, C. H. MORGAN (*Orange River Colony Dept. Agr., Ann. Rpt., 2 (1905-6), pp. 331-336*).—An attempt is being made to eradicate sheep scab by a simultaneous dipping of sheep throughout the colony. It is recommended that the period during which dipping should take place be reduced to 3 weeks. About 30 dips have been recognized in an official list, but lime and sulphur has given the best results and is recommended for general use. The application of carbolic dips or arsenical dips is subject to a number of disadvantages.

Reports of inspectors of stock for the year ended March 31, 1906, J. L. BRUCE (*New Zeal. Dept. Agr. Ann. Rpt., 14 (1906), pp. 141-179*).—During the season under report the general health of animals in New Zealand was quite satisfactory. A number of small outbreaks of anthrax occurred. Dairymen realize the importance of thorough milk inspection, and the regulation of the milk supply has been taken in hand more strictly than ever before.

During the past year the rabbit pest has caused considerable agitation among the farmers. In some localities objections have been raised to the use of poison in destroying rabbits, but the adoption of a bounty system has still more disadvantages.

Division of veterinary science, J. A. GILRUTH (*New Zeal. Dept. Agr. Ann. Rpt., 14 (1906), pp. 264-317, pl. 1*).—A statement is presented of the present organization of the veterinary force and the laboratory and meat inspection work. During the year there was only one outbreak of anthrax reported. A general discussion of tuberculosis is given with particular reference to its transmissibility from animals to man.

A number of experiments were carried out in the control of contagious mammitis. A highly recommended proprietary remedy used as an injection proved of no avail. Similarly injections of a 4 per cent solution of boracic acid failed

to bring about any rapid improvement in cases of the disease. Sodium fluorid used at the rate of from 1 to 5 parts per 1,000 gave better results when the treatment was continued for several days. None of these solutions, however, appeared to exercise any pronounced bactericidal effect. The method of making injections consists in introducing the solution into the affected quarter of the udder, after which the part is manipulated with the hands and the solution withdrawn after 10 minutes. The injection should be repeated 2 or 3 times daily.

Notes are also given on serum treatment for swine diseases, stomach staggers in horses, tumors in cattle, *Strongylus cervicornis* as a cause of parasitic gastritis in goats and other young stock, *S. strigosus* in rabbits, blackleg, and a new skin parasite of sheep apparently belonging to the genus *Hematopinus*.

Combating infectious diseases in the Transvaal, A. THEILER (*Deut. Tierärztl. Wchenschr.*, 14 (1906), No. 50, pp. 633-637).—Tuberculosis has not become generally established among domestic animals in the Transvaal, apparently for the reason that most stock is kept for a large portion of the year out of doors. Anthrax is likewise observed only sporadically. Particular attention has been given to the control of glanders, epizootic lymphangitis, and sheep scab.

Contagious diseases of live stock as affecting their market value, J. J. FERGUSON (*Amer. Breeders' Assoc. Proc.*, 2 (1906), pp. 145-147).—With the development of an effective system of inspection, the detection of contagious diseases in animals at large market centers has become easy. Statistics are given showing the number of animals of different kinds condemned at the chief inspection centers. It is suggested that plans be adopted by which the financial responsibility for disease in animals would fall more largely upon the first seller of the diseased animals.

Statistics on tuberculosis, J. BÖHM (*Ztschr. Fleisch u. Milchhyg.*, 17 (1907), No. 4, pp. 124-126).—In the author's opinion more care should be exercised in reporting statistics on tuberculosis to differentiate between the different forms of the disease. It is suggested that careful distinction be made between uterine, mammary, pulmonary, and intestinal tuberculosis.

Tuberculosis, S. S. CAMERON (*Jour. Dept. Agr. Victoria*, 4 (1906), No. 11, pp. 641-655, pl. 1).—The etiology, symptoms, prevalence, and pathology of this disease are described in considerable detail and notes are given on the various forms under which tuberculosis occurs. Particular attention is given to a discussion of the mammary form of tuberculosis.

Bovine tuberculosis, A. W. GILMAN (*Bul. Maine Dept. Agr.*, 5 (1906), No. 4, pp. 119-153).—The State department of agriculture of Maine has made a study of the prevalence of tuberculosis throughout the State and presents in this bulletin a general summary of the facts relating to the case. A copy is given of the State laws relating to tuberculosis, together with discussions by various authors on the infectiousness of the milk of tuberculous cows, the control of tuberculosis in cattle, the use of tuberculin, and related subjects.

The course of penetration of tubercle bacilli, A. CALMETTE (*Rev. Gén. Méd. Vét.*, 9 (1907), No. 98, pp. 49-57).—In the author's opinion, von Behring's contention that most cases of infection with tuberculosis occur in early life has not been proved. Animals appear to be almost equally susceptible to the disease at all ages; in fact, it is held that adults are even more susceptible than younger animals to infection through the alimentary tract.

The author has undertaken a series of experiments in the immunization of cattle to tuberculosis through the alimentary tract. It has been found that young or adult cattle which have been fed small quantities of tubercle bacilli attenuated by heat resist fatal doses of virulent bacilli when given with the food. It has not been determined how long this immunity persists.

Immunization of calves against tuberculosis, F. ONDRACEK (*Wiener Landw. Ztg.*, 57 (1907), No. 11, p. 93).—After a long experience with methods of controlling tuberculosis, the author recommends the clinical examination of cattle 3 times annually, diagnostic inoculations with tuberculin annually, and the vaccination of calves by the method of von Behring.

Vaccination for tuberculosis in cattle, ROSSIGNOL and H. VALLÉE (*Rev. Tuberculose*, 2. ser., 3 (1906), No. 6, pp. 466-472).—As the result of previous experiments in vaccinating cattle against tuberculosis at Melun, the authors came to the conclusion that vaccinated animals resist natural contagion from cohabitation with infected animals at least for a period of several months.

Further experiments have been carried out and animals previously treated have been kept under continued observation. It appears that bovo-vaccine shows some variation in virulence, as tested on guinea pigs, and it is therefore reasonable to suppose that its effects on cattle are not always identical. Cattle vaccinated by this method may be infected with tuberculosis by intravenous inoculation within 3 months, and immunity disappears entirely in some cases within a year. It was found that the resistance of vaccinated cattle to contagion from association with tuberculous cattle was not particularly marked and did not extend over a period of more than a few months. Judgment is therefore suspended regarding the ultimate value of this method of vaccination.

Tuberculosis of the esophageal musculature in cattle, MAY (*Deut. Tierärztl. Wchenschr.*, 15 (1907), No. 3, pp. 31, 32).—The tissues along the trachea and esophagus, particularly the lymphatic glands, are often involved in cases of pulmonary tuberculosis in cattle. In one instance the author observed isolated tubercles in the musculature of the esophagus and was led to believe that these tubercles were due to a secondary infection from bronchial slime.

Diagnosis of anthrax in practice, L. DE BLIECK (*Tijdschr. Veeartsenijk.*, 34 (1906), No. 3, pp. 109-151, pl. 1).—A detailed account is given of the means which may usually be adopted by the practicing veterinarian in making a bacteriological diagnosis of anthrax. The general discussion includes methods of identifying the anthrax bacillus, differential diagnosis between anthrax and related diseases, and the approved methods of sending material to laboratories for a bacteriological test.

Determining the effectiveness of anthrax serum, A. ASCOLI (*Ztschr. Hyg. u. Infektionskrankh.*, 55 (1906), No. 1, pp. 44-80).—As a result of a long series of laboratory experiments, the author comes to the conclusion that the intravenous inoculation of anthrax serum gives rabbits a pronounced passive immunity toward virulent anthrax cultures. The results which are obtained within 24 hours after the injection, however, are not sufficiently regular to form a basis for determining the value of the serum.

Under certain conditions anthrax serum has the power of protecting guinea pigs against cultures of anthrax bacilli. The passive immunity produced by intraperitoneal injection of anthrax serum is manifested within 24 hours, whereas after subcutaneous injection it does not appear before 72 hours.

A microscopic study of the colostrum and the udder of cows in cases of parturient paresis, N. P. RUKHLYADEV (*Uchen. Zap. Kazan. Vet. Inst.*, 23 (1906), No. 5-6, pp. 357-390, pl. 1).—An elaborate microscopical study was made on 14 cases of parturient paresis in cows for the purpose of identifying the various bodies found in the colostrum and udder in such cases.

During this investigation the author found in the colostrum casts and other bodies closely resembling them in structure, but having a different contour, and also fat globules, leucocytes, red blood and colostrum corpuscles, epithelial cells, and granular amorphous masses. The colostrum in cases of parturient paresis

contained more casts than are to be observed in normal cases either before or after parturition. The casts are very similar to renal casts, but vary in size and outline. Those observed by the author in the colostrum, like renal casts, may be granular, homogeneous, of mixed nature, or of formed cellular elements (leucocytes and epithelial cells). In addition to these casts lamellated bodies are observed in some parts of the sediment.

A study of sections of the mammary gland disclosed the presence of similar elements in this structure, both in the alveoli and in the various milk ducts. The casts observed in the udder are in general very similar to the renal casts, but show some characteristic features in connection with histological elements of the mammary gland. These casts are described as exudative casts of the udder. The author considers that his investigations indirectly substantiate the view that renal casts have their origin in albuminous exudates.

Stomatitis or sore mouth, J. SPENCER (*Virginia Sta. Rpt. 1906*, pp. 32-34).—Stomatitis in domestic animals may arise from a variety of causes, including mechanical, chemical, thermal, and bacterial irritants. The symptoms naturally vary according to the cause and stage of the disease, and the treatment must be adjusted to the cause. The usual treatment consists in a change of diet, in which the animal receives largely soft succulent food and the use of a mouth wash, such as chlorate of potash, creolin, or carbolic acid.

Foot-and-mouth disease, E. LECLAINCHE (*Rev. Gén. Méd. Vét.*, 9 (1907), No. 97, pp. 1-9).—Statistics are given on the prevalence of foot-and-mouth disease in Germany, Holland, Belgium, Switzerland, and Hungary, from 1888 to 1905, together with a brief account of the outbreak in New England. Suggestions are also made regarding suitable precautionary measures to be taken in controlling the disease.

Foot-and-mouth disease in the Villette market, VACHER ET AL. (*Bul. Soc. Nat. Agr. France*, 66 (1906), No. 9, pp. 746-758).—This is a symposium on the danger of the spread of foot-and-mouth disease in the cattle markets. The Villette market is considered as offering many opportunities for the rapid spread of foot-and-mouth disease, and stricter regulations for the control of this disease are believed to be necessary.

The bacteriolytic power of the blood serum of hogs, B. M. BOLTON (*U. S. Dept. Agr., Bur. Anim. Indus. Bul.* 95, pp. 62, figs. 4).—The investigations reported in this bulletin concern the reactions which take place between *Bacillus cholera suis* and normal and immune serum in hogs. Preliminary experiments were made with other bacteria. The Ehrlich theory of immunity is explained and illustrated for the purpose of indicating the bearing of the author's investigations upon the utility of the theory in the study of immunity.

The blood used in the experiments was drawn in a sterile condition from healthy hogs or from hogs injected from cultures of *B. cholera suis*. Care was taken to ascertain that at the beginning of the experiments all hogs were in a healthy condition. The bactericidal power of the serum was tested at different times by bleeding the same hog at intervals of a few days. The variation in bactericidal potency of the serum is presented in tabular form, and a comparison made of the variation between venous and arterial blood in this regard.

The author summarizes the conclusions drawn from his experiments as follows: The bactericidal potency of hog serum varies from time to time and differs somewhat for different strains of *B. cholera suis*. The attenuating effect of long standing is more marked in some samples of serum than in others under similar conditions, and the bactericidal power of venous blood is not always greater than that of arterial blood. The serum is rendered inactive

by subjection to a temperature of 54° C. for 30 minutes. The inactivity of immune serum except after dilution, which is known as the Neisser-Wechsberg phenomenon, was sometimes observed and sometimes absent. It is held that the theory of complement diversion by means of amboceptors may not only account for the behavior of immune serum but also that of normal serum.

The treatment of joint-ill, ECKARDT (*Wechschr. Tierheilk. u. Viehzucht*, 50 (1906), No. 49, pp. 961-969).—The treatments usually recommended for this disease have almost uniformly proved to be of little or no avail. The author states that for the past 10 years he has used with considerable success an indirect treatment through the milk of the mother. It was first determined by preliminary experiments that the direct administration of colloidal silver and iodid of potash had little effect in controlling the disease.

The treatment adopted by the author consists in administering iodid of potash to the mother in large doses. Mares and cows will take 200 gm. in drinking water during a period of 14 days without showing any ill effects. The iodid of potash is rapidly excreted through the milk and appears in large quantities within 3 days after the treatment has begun. Detailed clinical notes are given on 6 cases in which striking success was had from this treatment.

Glanders in the bone, W. VAN DER BURG (*Tijdschr. Veeartsenijk.*, 34 (1906), No. 2, pp. 53-57, figs. 2).—Brief reference is made to previous cases of this sort. The author had occasion to treat a case which had been diagnosed as a dermatitis, caused by friction of the harness. The horse soon showed symptoms of cutaneous glanders, and a post-mortem examination confirmed the diagnosis of glanders already reached by the author. Two of the ribs were badly affected with the glanderous process.

Mallein as a diagnostic and remedy for glanders, J. DE HAAN and L. J. HOOGKAMER (*Ztschr. Hyg. u. Infektionskrank.*, 55 (1906), No. 1, pp. 133-170).—The authors' experiments with mallein and observations on glanderous horses lead them to the conclusion that mallein is the best known diagnostic for latent glanders. In their experience, glanderous horses which show no fever before injection show an elevation of temperature of 1½ to 2° C. within 12 to 16 hours after injection. Even in healthy horses mallein may produce a considerable elevation of temperature after about 16 hours, but the temperature rapidly subsides.

It is recommended that all horses which react to mallein and also show clinical symptoms of glanders should be destroyed. Reactors which show no clinical symptoms and suspected cases are to be kept under observation for 4 weeks and again tested with mallein. The authors consider that glanders is curable. In some cases the cure takes place within a period of 6 months, provided the animals are kept under favorable hygienic and nutritive conditions. The repeated use of mallein is believed to favor recovery from the disease.

The treatment of morbus maculosus in horses, H. BECKER (*Ztschr. Veterinärk.*, 19 (1907), No. 1, pp. 26-28).—In connection with an outbreak of strangles a number of cases of morbus maculosus was observed. The author had good success in treating this trouble with a mixture containing one part camphor and 10 parts sodium chlorate in rye meal. Clinical notes are given on three cases in which this treatment was adopted.

"Pink eye" in Manchester, J. B. WOLSTENHOLME (*Vet. Rec.*, 19 (1907), No. 966, pp. 430-432).—The author presents a summary of his observations on 52 cases of influenza as observed in one institution. During the height of the disease the pulse ranged from 60 to 62. The conjunctiva of the eye was reddened in a majority of cases. Only 3 out of 52 cases died. The highest

temperature observed in any case was 106.2° F., while in 17 cases the temperature reached 105° F. In one of these 17 cases the high temperature persisted for 7 days. The age of the horses ranged from 4 to 16 years, but the larger number of cases occurred among horses which were 5 or 6 years old.

The disinfection of stalls with dilute formalin solutions. J. SCHNÜREN (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 2 (1906), No. 1, pp. 43-57).—It is often possible to get a better penetration with fluid than with gaseous formalin, especially in stables in which there are cracks in the floor and other parts. The author therefore tested the value of formalin in an aqueous 1 per cent solution. The disinfectant results were entirely satisfactory. The only disadvantage of the method consists in the fact that the fumes may be too severe upon the operator if the process lasts very long or in stalls where the ventilation is not good.

Trypanosomes. F. G. NOVY (*Jour. Amer. Med. Assoc.*, 48 (1907), Nos. 1, pp. 1-10; 2, pp. 124-127, figs. 10).—The structure and biology of trypanosomes, pathogenic for animals, are described in detail, and notes are given on the transmission of trypanosomes and on the immunity produced in animals against protozoan diseases. Specific accounts are presented on the nature, etiology, and method of treatment of nagana, dourine, Gambian horse disease, galziekte, sleeping sickness, and related diseases.

The cattle tick. W. NEWELL and M. S. DOUGHERTY (*Crop Pest Com. La. Circ.* 10, pp. 32, figs. 8).—The authors present a general discussion of the importance of tick eradication to the improvement of animal industry in the southern States.

The life history of the cattle tick is described with particular reference to its agency in transmitting Texas fever and to the adoption of rational schemes for its eradication. Tables are presented showing the periods during which cattle and other animals must be kept off of pasture lands at different seasons of the year in order to free these lands from ticks and make it safe to readmit tick-free cattle upon them. On the basis of this practical information it is a relatively simple matter for stock men to free farm lands of ticks.

Stomach worms (*Hæmonchus contortus*) in sheep. B. H. RANSOM (*U. S. Dept. Agr., Bur. Anim. Indus. Circ.* 102, pp. 7).—The symptoms of infestation by this worm are briefly noted. In preventing the infestation of lambs with stomach worms two general plans are usually applicable. The ewes may be kept in a bare lot from which the lambs may escape to noninfested pasture for grazing. The danger of infestation is thus reduced to a minimum. Again, wherever it is practicable, the danger of infestation from stomach worms is largely eliminated if the lambs come in the fall rather than in the spring.

Brief notes are given on the direct remedies for stomach worms, including coal-tar creosote, bluestone, and gasoline.

Department of animal industry. N. S. MAYO (*Informe An. Estac. Cent. Agron. Cuba*, 1 (1904-5), pp. 41-45).—A brief statement is made regarding the efforts put forth to improve the grade of domestic animals in Cuba, together with notes on some of the more important animal parasites of the live stock.

The urology of rabies. C. PORCHER (*Jour. Méd. Vet. et Zootech.*, 57 (1906), pp. 716-732).—A chemical and physical study of the urine in cases of rabies among dogs, rabbits, goats, and donkeys, disclosed the presence of sugar in nearly all cases which died of the disease or which were killed during its progress. On the other hand, the urine of healthy animals of the same species contained sugar in only 2 cases as contrasted with 29 cases in which no sugar was found. The sugar does not appear in advance of the development of the

symptoms of rabies and does not seem to bear any relation to the virulence of the rabies virus. Apparently it occurs with such regularity in the urine of rabid animals that it may be considered a diagnostic symptom.

Neutralization of rabies virus with the bile of biliary salts, C. LESIEUR (*Compt. Rend. Soc. Biol. [Paris]*, 61 (1906), No. 39, pp. 694, 695).—According to the experiments reported in this paper the bile of either normal or rabid animals has the power of neutralizing rabies virus in vitro within a few minutes. The biliary salts either isolated or in combination have the same power when used in solutions corresponding to those in which they exist in the bile. Injections of rabies virus neutralized by bile or biliary salts have no effect in preventing the development of rabies from subsequent inoculation with virus.

A study of the blood and cephalic fluid in dog distemper, J. SABRAZÈS and L. MURATET (*Rev. Gén. Méd. Vét.*, 8 (1906), No. 96, pp. 663-668).—In the nervous form of dog distemper a reaction is observed in the membranes of the brain. This reaction is characterized by a lymphocytosis and appears to be due to the toxic effect of the micro-organism of the disease, although the cephalic liquid is not infectious.

Surgical diseases and surgery of the dog, C. FRENCH (*Washington, D. C.: Author; London: H. Kimpton, 1906, pp. XIII + 498, pls. 29, figs. 52*).—The various pathological conditions which occur in dogs and which may be treated by surgical methods are discussed in a comprehensive manner. Some of the more important bibliographical references are given in connection with each chapter. The subject-matter of the volume is classified according to the parts of the body affected by various diseases.

Fowl cholera, M. FRANCO (*Lavoura; Bol. Soc. Nac. Agr. Brazil*, 10 (1906), No. 8, pp. 365-369).—The symptoms and pathological anatomy of this disease are described. The author has had some success in preventing it by giving with the feed a mixture containing hyposulphite of soda, salicylate of soda, gentian, ginger, and sulphate of iron.

RURAL ENGINEERING.

Disposal of dairy and farm sewage, and water supply, O. ERF (*Kansas Sta. Bul.* 143, pp. 125-139, figs. 8).—In this bulletin are included the results of sewage disposal experiments conducted by the dairy department of the Kansas Station, as a result of which "the station is now ready to advocate a system that is comparatively inexpensive and is practical for every farm. In fact, in some cases it has proven to be a source of great profit when used for irrigating and fertilizing truck patches and farm crops."

The method, in brief, is an adaptation of the well-known septic treatment in combination with a system of subirrigation by tiles to dispose of the tank effluent. Plans are shown and described for properly draining the barns and for conducting the sewage of the house, barns, and dairy through the septic tanks. Several alternate plans are presented for septic tanks suitable for farms of ordinary size. The total cost of construction of a circular septic tank 10 ft. in diameter and with concrete walls and floor and wooden partitions is estimated at \$42.50, while the cost of a rectangular tank of the same capacity 14 by 5 ft. over all, likewise constructed of concrete, is placed at \$41.10.

Some information is also included on the care to be taken in the location and construction of a well for the water supply of the house and dairy.

Eighth biennial report of the State engineer of Wyoming, 1905-1906 (*Bienn. Rpt. State Engin. Wyo.*, 8 (1905-6), pp. 162, pls. 10, map 1).—A report

covering the administrative and other work of the State engineer during the period 1905-6.

Great progress is reported in the development of irrigation in Wyoming, permits having been granted during the past two years for irrigating more land than is under irrigation in the State at the present time. These permits number 1,127 and provide for the reclamation of 1,315,011 acres of land, with 2,083 miles of canal and ditches, at a total estimated cost of construction of \$4,427,275. A good sign of substantial irrigation development is the number of reservoirs constructed, there having been 343 permits for such structures issued in the past two years.

The report includes detail tables of the various permits and certificates issued, some discussion of the operation of land laws, a report of the surveys conducted by the State on the Shoshone Reservation, reports of the superintendents of the various water divisions, and the report of a committee appointed to revise, codify, and simplify the laws of Wyoming relating to water rights.

Farm irrigation in the Transvaal, C. D. H. BRAINE (*Transvaal Agr. Jour.*, 5 (1907), No. 18, pp. 354-361, figs. 3).—In discussing suitable methods to be used in the irrigation of orchards the author suggests a new system which it is claimed will supply the water where it is most needed, at the roots of the tree. The method proposed is, in brief, to sink one or more pits the size of a post hole and about 2 ft. deep between each pair of fully grown trees, the depth and distance apart depending, however, upon the root system of the trees, the nature of the ground and subsoil, and the kinds of trees or plants. The holes are filled with grass, leaves, or straw to prevent the subsoil from drying out. Permanent holes may be lined with old bricks or drain pipes.

Hydraulic-ram boring apparatus (*Engin. and Min. Jour.*, 83 (1907), No. 16, pp. 761, 762, figs. 4).—A description of a deep-boring apparatus developed in Germany and embodying several novel features applicable to the boring of deep wells and explorations of underground strata.

The principle of the apparatus is that of the hydraulic ram. A number of plungers, to the lower ends of which are attached the chisels, are contained in a drum-like casing which is slowly revolved. Water admitted through a pipe extending to the surface acts upon the plungers, to which a reciprocating motion is given as a result of the hydraulic-ram effect of the descending water, which acts upon and closes a valve, causing impact upon the plunger, after which the latter is returned to its original position by a spring. The water used flows over the surface acted upon by the chisels and produces a thorough rinsing, most of the sediment being conveyed to the surface by the upward current.

From 600 to 1,000 blows of the chisels are claimed per minute, and it is stated that holes of very large diameter may be bored. The use of such apparatus for deep-well boring in the artesian districts of this country and in those localities where wells are used for irrigation might be attended with some success.

Some notes on the storage and regulation of water for irrigation purposes, T. W. SEAVER (*Jour. and Proc. Roy. Soc. N. S. Wales*, 39 (1905), pp. XLIII-LXII, fig. 1).—The author describes in the course of his discussion a simple but ingenious module, which is intended to provide a means for delivering a fixed quantity of water per minute independent of the stage of water in the supply tank or canal. It consists of a gate, free to slide up and down in front of the outlet, and suspended by a chain from one end of a lever, the other end of which is attached to a tank floating in the main canal.

To adjust the apparatus the gate is so placed that it will discharge the required amount of water under a given head. The chains from the gate and

tank are stretched taut up to the lever and the position of the latter marked on a board held vertically. By repeating this process for various heads, keeping the chains of the same length, a series of lines are obtained on the board. A curve is drawn tangent to these lines and the board sawed to the curve. If the lever is now placed upon and allowed to roll on the curve, the relation between the head of water and the size of the outlet must be such as to give a constant discharge from the outlet.

Thirteenth annual report of the commissioner of public roads, 1906 (*Ann. Rpt. Comr. Pub. Roads N. J., 13 (1906), pp. 176, pls. 12, map. 1*).—A report covering road construction and improvement in the various counties of New Jersey, giving the total mileage and cost. A number of papers, contributed by the county engineers on various subjects connected with road construction, and statistical data on the detail cost of various roads, together with the standard State specifications, form the greater portion of the report.

The value of oil in road improvement, A. DICKENS (*Kansas Sta. Bul. 142, pp. 113-124, fig. 1*).—This bulletin contains the results of the experiments conducted in certain parts of Kansas, as authorized by the legislature, on the use of crude oil for the improvement of public roads. Several short road sections were treated at Manhattan, Hutchinson, Maple Hill, and at Garden City, the experiments consisting in general of first putting the road in a fair condition, and then plowing it to a uniform depth and thoroughly pulverizing it with harrow and disk. Where the soil was loose sand, the road was merely worked to the proper form. The oil applied was what is known as residuum from the refineries, preliminary laboratory tests having shown that 1 gal. of residuum was equal in road-making qualities to from 2 to 4 gal. of the various oil samples. The oil was applied by a special sprinkling arrangement attached to a street sprinkler, the amount used varying from 0.5 to 6 gal. per square yard according to the conditions of the experiment. Observations were made upon the behavior of the road under traffic, and although the tests are regarded as incomplete the following conclusions were drawn:

“The thorough mixing of the earth and soil to a sufficient depth to form a waterproof crust is necessary. For heavy traffic, not less than 6 in. is desirable; for light driving, 3 or 4 in. should be sufficient.

“Oil roads will probably require repeated applications of oil, but it now seems that the amount required will decrease annually as the roads become smoother.

“With residuum at \$6 cts. to \$1 per barrel f. o. b., the total cost of road varied from \$525 to \$1,300 per mile for an 18-ft. road.”

Alcohol motors in agricultural operations (*Deut. Landw. Presse, 34 (1907), No. 26, pp. 217, 218, fig. 1*).—The writer takes up some of the advantages of the alcohol motor in agricultural operations in Germany. Among these, he refers to the facility with which the motor can be put in operation as compared with the steam engine, in case it is desired to complete harvesting and threshing operations in anticipation of approaching bad weather, when the time required to fire a boiler and get up steam might mean the loss or injury of a portion of the crop. The absence of smoke and sparks is also thought to be an advantage over the steam engine in field use, as is also the fact that the use of the alcohol motor does not necessitate the expense of hauling water, the water consumption of the alcohol engine for cooling purposes being only about $\frac{1}{2}$ gal. per horsepower hour, or 24 to 26 gal. water per day for a 12-horsepower engine.

To show the relative cost of different fuels, some tests are reported on a special motor in which, by the addition or removal of plates on the piston head, the compression can be conveniently changed for various fuels, such as alcohol and the other usual hydrocarbons, a compression of 15 atmospheres being used

with alcohol. The fuels tested were benzine, alcohol, and a mixture of alcohol with benzol and ergin. The motor was rated at 16 horsepower, but in the test with pure motor alcohol 21.96 horsepower was developed. The investigation proved that a mixture of ergin or benzol considerably lowered the fuel consumption, and at the present price of alcohol, benzol and ergin mixtures therefore considerably reduce the operating cost.

The following table shows the several fuel consumptions in pounds per brake horsepower hour:

Fuel consumption per brake horsepower hour.

Load in horse-powers.	Pure motor alcohol.	90 per cent alcohol, 10 per cent benzol.	70 per cent alcohol, 30 per cent benzol.	50 per cent alcohol, 50 per cent benzol.	90 per cent alcohol, 10 per cent ergin.	75 per cent alcohol, 25 per cent ergin.	50 per cent alcohol, 50 per cent ergin.
	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>
20.25	0.84	0.73	0.66	0.58	0.76	0.69	0.62
16.22	.87	.77	.69	.61	.79	.72	.64
10.14	.96	.89	.80	.72	.92	.81	.78

In order to ascertain the cost of operation from these values, the mean consumption of 0.62 lb. per horsepower hour was assumed for a 12-horsepower engine adapted for use on a threshing machine. At the present prices in Germany of alcohol and the mixture ingredients, it was found that the cost of operation would be \$1.90 per 10-hour day. The writer concludes that in view of the many advantages of the alcohol engine and the fact that it uses as fuel an agricultural product, such an engine is the most suitable of all the prime movers for farm purposes.

Industrial alcohol: Its manufacture and uses, J. K. BRACHVOGEL and C. J. THATCHER (*New York: Munn & Co., 1907, pp. 516, figs. 197*).—After a general discussion of the adaptability of denatured alcohol to various purposes and its importance to the farming interests of the country, the authors devote several chapters to an account of the materials and processes involved in alcohol manufacture. Following this, some data, mostly compiled from foreign sources, are given on the use of alcohol for power, heating, and illumination, and statistics are presented on alcohol production in the United States and foreign countries.

Three months of denatured alcohol (*Sci. Amer., 96 (1907), No. 14, pp. 286, 287*).—In this article attention is directed to the present status of the alcohol industry under the denatured alcohol law, it being pointed out that no sweeping revolution of industrial or agricultural conditions, such as was predicted prior to the passing of the act, has as yet been brought about. Although certain ethyl alcohol industries have been stimulated, methyl alcohol production has in no way been materially affected. It is stated that denatured alcohol is now obtainable at from 35 to 40 cts. per gallon, depending upon the locality, and while this price prohibits active competition with gasoline or kerosene at present prices, there is every reason to believe that it will eventually decrease in price when uses are found for the by-products of its manufacture, and when its uses as a fuel and in the arts become more widespread.

The recent amendment to the law is mentioned in connection with the manufacture of alcohol on a small scale. Under this amendment denaturing warehouses may be dispensed with when the capacity of the still is less than 100 proof gals. per day, the alcohol being conveyed to warehouses for denaturing by pipes or cars. It is the opinion of the writer, however, that communal rather than individual distilleries, or, in other cases, distilleries operated on

the principle of the old-time grist mill, are the real hope of the farmer. "Even if small distilleries can be installed at a comparatively low cost alcohol can be distilled economically and profitably only when the production is continuous and on a larger scale than is possible on the average farm."

The engineering index, H. H. SUPLEE, J. H. GUNTZ, and C. B. GOING (*New York and London: Engin. Mag., 1907, vol. 4, pp. 1234*).—A large volume containing an index and brief digest of articles which have appeared in foreign and domestic periodicals during the past three years on all phases of engineering information, the book being of value to the rural engineer particularly for its references to irrigation, drainage, farm machinery, and related topics.

RURAL ECONOMICS.

Farm management, F. W. CARD (*New York: Doubleday, Page & Co., 1907, pp. XIII+270*).—This is the fourth volume in the Farm Library series.

The book is an outgrowth of a course of lectures to students at the Rhode Island College of Agriculture on the problems of the farm, the aim being to awaken interest and suggest methods of studying these problems rather than to present solutions of them. Practical suggestions regarding many economic phases of farm management are made with the view of showing that, under capable direction, farming as a business will compare favorably with many professional and industrial pursuits. In the author's opinion "farm administration, rather than farm production, is likely to receive special emphasis in the next forward movement for agriculture."

The scarcity of farm help and the remedy, K. OLDENBERG (*Ztschr. Agrarpolitik, 5 (1907), No. 2, pp. 74-86*).—The author calls attention to the lack of trained farm laborers in Germany due to the exodus into cities and to foreign emigration. The shorter hours of service, steady employment, and higher wages of industries, together with the social advantages in towns and cities over country life, are regarded as the chief causes of rural depopulation. Among the remedies suggested are the adoption by landowners of industrial methods as to hours, wages, employment, etc., the establishment of a government bureau to place the unemployed on farms, land colonization, and the teaching of agriculture in public schools. The last is regarded as likely to be most effective in ultimately turning the tide of emigration back to farm life.

Foreign agricultural laborers in France, M. LAIR (*Rev. Écon. Internat., 1 (1907), No. 3, pp. 527-570*).—Statistics are given which show that there has been a gradual reduction in the number of native farm laborers in France and a corresponding immigration of Belgians, Swiss, Germans, Italians, and Spaniards to do farm work.

The author describes the method of securing foreign laborers, their mode of living, hours of labor, wages received, and the advantages and disadvantages of this class of labor from the economic and national points of view. The majority of farm laborers work from spring to fall in France and then withdraw to their respective countries, taking with them annually in wages about 20,000,000 francs. At the same time statistics secured from magistrates in numerous districts show that crops could not be harvested without foreign help on account of rural depopulation in France. For this reason the difficulties in the way of legislation regarding foreign farm immigration are pointed out. This class of farm help is regarded as industrious, as of great importance in increasing the wealth of the country, and as presenting no danger regarding the deterioration of the French race.

The present importance of share farming in Tuscany, A. GORI (*Atti R. Accad. Econ. Agr. Georg. Firenze*, 5. ser., 3 (1906), No. 4, pp. 339-354).—The author describes various socialistic and communistic plans that have been proposed and practiced from time to time as a solution of the labor problem, presents a view of partnership farming in Tuscany, and shows how this method has resulted in improving the condition of farm laborers. The intellectual, moral, and physical well-being of farmers under this system is said to be greatly superior to that of industrial workers. Farming on shares is believed to offer a solution of the conflict between capital and labor in the rural districts of Tuscany.

Agriculture in Lombardy, P. ROUX (*Jour. Agr. Prat.*, n. ser., 13 (1907), No. 7, pp. 212-214).—The author describes farming under the metayer or share system in northern Lombardy, where intensive culture predominates and the vine and silk raising are the chief industries, and farming under irrigation in the south, where diversified farming and dairying are practiced. The methods of cultivating the various crops and the relations of metayer to proprietor are described.

Conditions of farm life in Lombardy (*Agr. Mod.*, 13 (1907), No. 9, pp. 127-129, figs. 2).—The author describes a colonial farm and farmhouse as typical of the economic and social conditions of the peasantry of Lombardy. The returns for labor are said to be small; corn, rice, vegetables, and milk, with very little meat and cheese, form the principal part of the diet; while the dwelling rooms are small and overcrowded. The conditions surrounding the life of the peasantry are said to be far from enviable throughout the province.

Agricultural cooperation in Ireland, P. LAVOLLÉE (*Bul. Soc. Agr. France*, 1907, Mar. 15, pp. 667-673).—This is a résumé of a pamphlet by G. de Kozielski Kossilowski on agricultural cooperation in Ireland.

The writer describes the organization and aims of cooperative creameries, agricultural societies, rural banks, poultry and egg societies, and other organizations, the data showing that there were in 1894 a total of 34 societies with 1,650 members, while in 1904 the figures were 778 and 76,963, respectively. The land law of 1903 is said to work favorably for the tenants. By its provisions the tenant under certain conditions can become the owner of land, advances being made by the government. At the close of 1904, 6,826 had taken advantage of the law and acquired possession.

The credit banks and the home industries societies are particularly commended. The banks number 200, with 11,257 members, and through them the department of agriculture advances to members sums ranging from £25 to £100, at 3 per cent interest. The home industries societies, the writer thinks, are worthy of introduction into France as a means of preventing foreign emigration and rural depopulation, both of which tendencies have diminished lately in Ireland on this account.

Agriculture in New Zealand, R. MCNAB (*Wellington: Govt.*, 1906, pp. 20, pls. 20).—This pamphlet, by the minister for agriculture, gives information regarding the soil, climate, rural industries, and agricultural exports, with notes on government aid to agriculture and the land system of New Zealand.

The country is said to be peculiarly adapted to the raising of stock, while the yields of grain are the highest of any in the world with the exception of those of Great Britain. The colony's chief exports consist of wool, frozen meat, and dairy produce, and the agricultural products exported in 1905 were valued at £12,046,268, or 77 per cent of the total exports. The area in occupation in October, 1905, was 37,167,460 acres, of which 14,222,629 acres were under cultivation.

Agricultural returns for 1905 (*Recensement Agricole de 1905. Brussels: Min. Agr., 1906, pp. 261*).—The conditions which prevailed in the various provinces of Belgium during the year are described, and detailed statistics of hectares under crops, utilization of commercial fertilizers and feeding stuffs, number of domestic animals, etc., in comparison with the preceding year are reported. The number of farms in 1905 was 296,314, number of hectares cultivated 1,761,759, commercial fertilizers used 713,498,300 kg., feeding stuffs used 2,269,579,200 kg., and number of domestic animals 1,046,519.

Mutual agricultural fire insurance [in France] (*Semaine Agr. [Paris], 26 (1907), No. 1348, pp. 82, 83*).—An abstract of the annual report of the Mutual Agricultural Fire Insurance Societies of the East.

The report shows 450 affiliated societies; policies issued and reinsured during 1906, 2,400, covering risks to the amount of 20 million francs; present proprietors insured, 12,000, representing a capital of nearly 120 million francs; and a reserve fund of more than 300,000 francs.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 9 (1907), No. 4, pp. 25-32*).—Statistics and notes on the condition of crops and animals and the supplies and prices of agricultural products in the United States and foreign countries are summarized. Data are given on the growth of the condensed-milk industry. In 1880, 13,033,267 lbs. were produced, valued at \$1,547,588, while in 1905 the output was 308,485,182 lbs., valued at \$20,149,282.

AGRICULTURAL EDUCATION.

Annual report on the distribution of grants for agricultural education and research (*Bd. Agr. and Fisheries [London], Ann. Rpt. Agr. Ed. and Research, 1905-6, pp. X+191*).—This report consists of a general report on the work of the year 1905-6, a list of the grants awarded, and four appendixes: (1) Reports on institutions receiving grants, (2) methods adopted by county councils for giving instruction in the manual processes of agriculture, (3) agricultural instruction provided by county councils in England and Wales in the year 1905-6, and (4) a statement showing the amount received in 1904-5 from the residue grant under local taxation and the expenditure for agricultural instruction in 1905-6 by county councils in England and Wales.

In the general report, attention is called to grants of \$4,856 each to two additional institutions, the Hampshire Farm School at Basing, and the Ridgmont Agricultural Institute in the county of Bedford, both of which in their winter work correspond to the winter schools of Germany, and in the summer are conducted as dairy schools, mainly for young women. The number of students in the agricultural courses of the different institutions in 1905-6 is estimated at 34,000, as compared with 23,000 in 1904-5. The board has decided to issue a series of short monographs for farmers dealing with the results of agricultural experiments and demonstrations conducted under its direction. It is shown that in the different institutions 300 teachers took advantage of the special courses for teachers as compared with 238 in 1904-5.

The appendix on instruction in the manual processes of agriculture is mainly a compilation of replies received in response to a circular letter addressed to the several county councils for the purpose of learning what they were doing in the way of providing instruction in agricultural practice. It was found that the subjects in which instruction is given comprise plowing, drilling, mowing, setting out roots, harvesting, setting up sheaves, stacking, thatching (including rope and spar making), hurdle making, basket making, sheep-shearing, milking, hedging and ditching, land draining, pruning, grafting, budding, hop drying,

and fruit packing. In the majority of cases instruction was given for at least two hours a day and for 6 or more days, and the course usually ended with a competition and prizes for skill in the work that had been undertaken.

The development of agricultural education in Scandinavia, A. YSTGARD (*Ill. Agr.*, 11 (1906), No. 3, pp. 90-98).—The writer reviews briefly the history of agricultural education, tracing it back to the garden of Albrecht Thaer, in the province of Hannover, Germany, at the end of the eighteenth and the beginning of the nineteenth centuries. He shows the development in the Scandinavian countries of elementary schools, their decline on account of a dearth of properly trained instructors, the rise of the higher agricultural institutions, and the subsequent development on a better basis of the elementary schools.

Tables are given showing 1 agricultural college and 33 lower agricultural schools in Norway, 2 agricultural colleges and 57 lower schools in Sweden, and 1 agricultural college and 23 lower schools in Denmark. Another table shows the area of these 3 countries, the population, and the percentage of rural population. The agricultural colleges in each of the 3 countries are briefly described. There is also a discussion of the elementary and special schools in the different countries.

An experiment in school consolidation in Canada, G. P. PHENIX (*South. Workman*, 36 (1907), No. 2, pp. 79-86, figs. 5).—This is a description of the Macdonald Consolidated School in New Brunswick, which is located about 20 miles north and 12 miles west of St. John in the hamlet of Kingston. It is shown that while before consolidation the enrollment in the 7 districts was 125, after consolidation it rose to 166 in the first term and 175 in the second. The average attendance in the unconsolidated schools was 44 per cent of the enrollment and in the consolidated school 84 per cent. Thus the daily attendance has been trebled and the percentage of attendance doubled.

The writer states that "the real secret of the success of this school at Kingston is to be found in the intrinsic worth of the course of study and in the strength of the instruction in the school itself. The difference between the course of study here and in the ordinary country school is sufficiently suggested by the difference in equipment. The orchard, the grafting tools, the pruning knives, the spraying apparatus, the kitchen with all its household implements, the sewing tables, the benches and tools, and the laboratory for indoor work in the winter—all utterly foreign to the ordinary school—here have a definite use."

Figures are also given to show the influence of agricultural education upon the dairy industry in Canada.

Statistics of educational institutions, 1903-4 (*Österr. Statist.*, 77 (1906), No. 2, pp. XXV+288).—These statistics, published by the Royal Statistical Commission of Austria, show the classes and location of educational institutions, including agricultural and forestry schools, together with their date of organization, length of courses of study, number of persons in faculties, number of students in attendance, etc. Under agricultural and forestry institutions there are listed the agricultural division of the Royal University at Krakow, the agricultural high school at Vienna, 20 secondary and middle schools, and 162 elementary schools. The total attendance at these schools in 1903-4 was 6,690.

MISCELLANEOUS.

Eighteenth Annual Report of Connecticut Storrs Station, 1906 (*Connecticut Storrs Sta. Rpt.*, 1906, pp. XXIII+296).—This contains a financial statement for the fiscal year ended June 30, 1906, reports of the director and heads of the departments, reprints of Bulletins 38-42 of the station, issued during the year, and a classification of dairy bacteria noted briefly elsewhere.

Sixteenth Annual Report of Kentucky Station, 1903 (*Kentucky Sta. Rpt. 1903, pp. XI+322*).—This report, recently issued, contains the organization list, a financial statement for the fiscal year ended June 30, 1903, a report of the director on the work of the station during that year, reprints of Bulletins 105–112 of the station, miscellaneous chemical analyses made in 1903 and not previously published, and meteorological observations noted elsewhere.

Seventeenth Annual Report of Kentucky Station, 1904 (*Kentucky Sta. Rpt. 1904, pp. XIV+202*).—This report for 1904 is similar in form to the above. Bulletins 113–117 are reprinted.

Eighteenth Annual Report of Kentucky Station, 1905 (*Kentucky Sta. Rpt. 1905, pp. XVII+246*).—This covers the work and expenditures of the station for the year ended June 30, 1905. The report of the director includes a summary of the work of the station in regard to pure food. Bulletins 118–123 of the station are reprinted.

Nineteenth Annual Report of Louisiana Stations, 1906 (*Louisiana Stas. Rpt. 1906, pp. 28*).—This contains the organization list; reports on the work at the Sugar Station at Audubon Park, the State Station at Baton Rouge, and the North Louisiana Station at Calboun; brief statements concerning the geological and soil surveys in the State; notes on the Adams Act, the meeting of the American Association of Agricultural Colleges and Experiment Stations at Baton Rouge, and on the experiment station exhibit at the State fair; and a financial statement for the fiscal year ended June 30, 1906.

Director's report for 1906, W. H. JORDAN (*New York State Sta. Bul. 284, pp. 329–350*).—A review of the different lines of station work during the year.

List of cooperative experiments for 1907 (*New York Cornell Sta. Bul. 242, pp. 36–43*).—This is a schedule of the experiment demonstrations offered to New York farmers during the season of 1907. The experiments cover a wide range of subjects, which are grouped into 8 divisions, each in charge of a specialist. The divisions are as follows: Agronomy, plant selection and breeding, horticulture, entomology, animal husbandry, poultry husbandry, dairy industry, and plant diseases.

Report on the Southern Utah Experiment Station, 1906 (*Utah Sta. Bul. 97, pp. 24*).—A brief statement on the work of this station is made by the director and a more detailed report is made by the horticulturist. The latter report is abstracted elsewhere.

Report on the Central Utah Experiment Station (*Utah Sta. Bul. 98, pp. 25–44*).—This contains the act establishing the Central Utah Experiment Station, brief statements by the director on the organization and work of the station, and reports of the horticulturist, agronomist, and irrigation engineer. The report of the horticulturist is abstracted elsewhere.

Annual Report of Virginia Station, 1906 (*Virginia Sta. Rpt. 1906, pp. 60*).—This report contains the organization list of the station; a report of the director discussing the personnel, resources, needs, etc., of the station; a list of available bulletins; a financial statement for the fiscal year ended June 30, 1906; and departmental reports containing several original articles which are abstracted elsewhere in this issue.

Literature, November, 1904, to January 1, 1907 (*Ztschr. Agrarpolitik, 5 (1907), No. 3, Beilage, pp. 83*).—This is a classified bibliography of German books and periodical literature for the period specified. It includes political economy, veterinary medicine, animal industry, fertilizers, soils, field and horticultural crops, meteorology, forestry, and other topics.

NOTES.

Arizona University and Station.—The resignation is noted of V. A. Clark, agriculturist and horticulturist.

Connecticut Stations.—By an act approved May 1 the legislature has formally acceded to the provisions of the Adams Act, and provided that the funds shall be divided equally between the State and Storrs stations.

Florida University and Station.—H. P. Stuckey, assistant horticulturist at the Alabama Station, has been appointed assistant in cotton work in the station. The visiting committee from the legislature has recommended an appropriation of \$40,000 for the erection of a building to be used for station, administrative, and laboratory purposes, and \$5,000 a year for the ensuing biennium for farmers' institute work.

Idaho University and Station.—J. R. Shinn, field assistant in pomology in the Illinois Station, has been appointed professor of horticulture in the university and horticulturist in the station. A department of dairying has been established under the direction of J. H. Frandson, a graduate of the Iowa College, as professor of dairying in the university and dairyman in the station. It is planned to develop materially the work in dairying.

Iowa College.—According to *Breeders' Gazette*, V. R. Gardner, instructor in horticulture, has been elected assistant horticulturist at the MacDonald Agricultural College.

Kansas College and Station.—A recent act of the legislature designates the college as the State highway commission, and among its duties specifies the devising of plans and systems of highway construction and of regulations for the repair and maintenance of highways, the conducting of demonstrations in road building at the request of the county commissioners, the providing of trained demonstrators for this purpose, and the disseminating of information among the county commissioners, highway officials, and the general public. The department of domestic science is conducting a month's dietary study among its students. W. E. Mathewson has returned to the college as assistant professor of chemistry and assistant chemist in the station.

Kentucky College and Station.—H. W. Taylor, assistant entomologist and botanist in the station, has resigned to accept a position in the Indian Industrial School at Carlisle, Pa. The board of control of the station has authorized the construction of a piggery and of a propagating house. One wing of the agricultural building for the college is now being erected.

Louisiana University and Stations.—The university announces the establishment of a school of agriculture modeled closely after that at the Minnesota University. A. E. Dodson, farm manager at the Audubon Park Station, has resigned.

A description is given in *Demeter* of the new chemical laboratory in process of construction. A 3-story brick structure is being erected, with an interior of

reinforced concrete and steel, and fireproof throughout. The building is designed to accommodate over 1,000 students and will contain a main lecture room seating 200, a general laboratory for 170, smaller lecture rooms and laboratories, a library and reading room, offices, museums, etc. Special provision has been made along industrial lines. The basement will contain furnaces for assaying, ceramics and clay working, and special laboratories will be fitted up for work in agricultural analysis and the chemistry of the sugar, cotton, rice, and petroleum industries and their by-products. It is claimed that the laboratory as a whole will rank when completed among the largest and best equipped in the South, and that the sugar laboratory will be the most complete of its class in the world.

Maine University.—The college of agriculture has arranged for two months of demonstration work, beginning July 15. Under the proposed plan, a member of the staff will hold an afternoon meeting at some farm at which a practical talk and demonstration will be given. The subjects include milk testing, spraying, pruning and grafting, soil fertility, home mixing of fertilizers, and other topics. Arrangements have also been made to establish a forestry experiment station in cooperation with the Forest Service of this Department. The university is to provide 5 acres of land and will exercise immediate supervision of the experimental work. The object will be to determine the species and cultural methods best suited to Maine conditions. Prof. G. E. Tower is to be in charge.

Massachusetts College and Station.—A department of agricultural education has been established, its duties to include both instruction and research. This is an entirely new departure at the college and is believed to be the first attempt in this country to organize this kind of work on so broad a foundation. Normal courses will be offered to prospective teachers, and studies will be made of problems confronting agricultural teaching in colleges and schools of various grades, and of agricultural extension with a view to introducing agriculture into the elementary schools, establishing agricultural high schools, and correlating and unifying the agricultural instruction given in the State. The work will be in close cooperation with existing educational agencies, especially the State industrial commission. W. R. Hart, of the Nebraska State Normal School, who has had long experience in teaching and is the author of a number of monographs and other articles on educational topics, has been selected as the head of the department and will begin his duties with the next college year.

F. C. Kenney, at present assistant secretary of the Michigan College, has been appointed treasurer and will act as the business agent of the college and station.

Missouri University and Station.—Dr. R. M. Bird, assistant professor of agricultural chemistry and assistant chemist in the station, has resigned to accept a position as professor of undergraduate chemistry at the University of Virginia. A. E. Grantham, instructor in agronomy and assistant agronomist, has also resigned. P. L. Gile, a graduate of Harvard University, has been appointed assistant in chemistry, and F. G. King, a graduate of this university, assistant in animal husbandry in the university and assistant in feeding in the station.

Nebraska University and Station.—The legislature has appropriated \$100,000 for new buildings and improvements, including \$20,000 for the completion of the woman's building, \$35,000 for a heating and power plant, \$30,000 for a stock and grain judging pavilion, and \$15,000 for a steer-feeding plant, tool barn, houses, etc. An appropriation has also been made of \$25,000 for the sub-station at North Platte, about \$10,000 of which will be used for permanent improvements and the remainder for maintenance during the ensuing biennium.

New Hampshire College and Station.—At a recent meeting of the board of trustees the presidency of the college and directorship of the station were

separated. E. D. Sanderson, professor of entomology and zoology in the college and entomologist in the station, becoming director.

New Jersey Stations.—James W. Kellogg has been appointed assistant chemist.

North Dakota College and Station.—A new board of trustees has been appointed, of which G. B. Hollister and C. E. Nugent, both of Fargo, have been chosen, respectively, president and secretary-treasurer. Additional appropriations have been secured from the legislature for the erection of an experimental milling building, the establishment and maintenance of a substation at Williston for the study of irrigation and dry-land methods, the construction and equipment of a horticultural greenhouse, and other purposes.

Oregon College.—W. J. Kerr, now president of the Utah College, has been elected president and will assume his duties July 1.

Porto Rico Station.—Oscar Loew, recently of this Department and at present connected with the College of Agriculture of the Imperial University of Tokyo, has been appointed chemist to the station. He will enter upon his new duties about October 1.

Rhode Island Station.—A study of the soil and manurial requirements for certain plants grown under glass has been begun in the new greenhouse.

Utah College and Station.—At the recent session of the legislature a department of horse breeding was established at the college, with the animal husbandman and veterinarian in charge. Their duties include the licensing of all stallions standing for public service, the law being modeled after that in Wisconsin. G. M. Turpin has resigned as assistant chemist in the station.

Virginia College and Station.—Dr. Paul Barringer, dean of the medical department of the University of Virginia, has been elected president. W. A. P. Moncure, instructor in mycology in the college and assistant mycologist to the station, has resigned. Arrangements have been made to continue for another year the experiments in tobacco growing in cooperation with the Bureau of Soils.

Wyoming University.—The protracted litigation between the university and the Lander Agricultural College as to the disposition of the Federal funds has been terminated by a decision of the U. S. Supreme Court sustaining the contention of the university, which will therefore continue to be the recipient. The opinion was by Justice Moody, who held that these Government grants are to the State and not to a particular institution.

Agriculture in Summer Schools for Teachers.—Instruction in one or more lines of agriculture, nature study, and domestic science will be offered during the summer by Cornell, Illinois, Maine, Ohio State, and Tennessee universities, Connecticut Agricultural College, Washington State College, and the Stout Manual Training School of Menomonie, Wis. The New Jersey State board of education and State board of agriculture will unite in conducting a school of agriculture, industrial arts, and sciences at Cape May City, with courses in agriculture, home economics, and manual training. Other summer schools of agriculture have been noted in previous issues.

Forestry School in North Dakota.—Under authority of a law passed several years ago, a State school of forestry was opened January 7 at Bottineau, N. Dak., with an enrollment of 30 pupils. Since that time the State legislature has appropriated \$25,000 for the erection of a new building. R. R. Thompson is in charge of the school, which offers courses in silviculture, soil physics, forest physiography, entomology, and plant pathology, and field work in horticulture, nursery, and forest planting. These courses are supplemented by courses in other sciences, mathematics, language, history, and civics, as well as by one year's work in the common branches in a preparatory department.

A New School of Horticulture and Basketry.—The minister of agriculture of France has recently issued a decree establishing the National School of Horti-

culture and Basketry of Fayl-Billot in the department of Haute-Marne. The citizens of Fayl-Billot and the syndicate of basket makers in the region have given the necessary land (22 acres) and \$15,440 for the erection of buildings. The department of Haute-Marne is to give \$200 and the ministry of commerce and labor \$1,351 annually toward running expenses. The faculty will consist of a director and about 6 other instructors, and the course of study will extend over 3 years. Eugene Leroux has been appointed director of the school.

Schools Gardens in the District of Columbia.—At the last session of Congress an appropriation of \$1,000 was made for the purpose of continuing and extending the school-garden work which has been carried on for a number of years in a cooperative way by the public schools and this Department. Beginning 4 years ago with a few gardens on the Department grounds and a little improvement work around a single school, the movement has grown until this year 700 children have gardens on the Department grounds, 124 school buildings in the District have gardens, and 160,000 packets of seeds have been sold for home gardens.

Massachusetts Forestry Legislation.—By a series of acts recently passed by the Massachusetts legislature, the salary of the State forester is increased from \$2,000 to \$3,000 per annum, the appointment by the local authorities, subject to his confirmation, of forest wardens with increased powers and duties is provided, and more stringent regulations are enacted for the better protection from fire of woodlands adjoining railroads. The limit of annual expenditure for forestry purposes of \$5,000 is amended to permit the use of such funds as may be annually appropriated, and \$2,000 may be expended in holding State conventions of the fire wardens.

Miscellaneous.—James A. Wilson, a graduate of the Minnesota School and College of Agriculture, now assistant professor of agriculture at the Crookston (Minn.) Agricultural High School, will succeed K. C. Davis as principal of the Dunn County School of Agriculture and Domestic Economy, Menomonie, Wis., at the beginning of the next school year.

Science notes the resignation of Prof. F. H. Storer, since 1870 professor of agricultural chemistry at Harvard University and dean of Bussey Institution, and his appointment as professor emeritus to date from September 1.

A recent number of the *Illustrierte Landwirtschaftliche Zeitung* states that Prof. J. Wortmann, of Geisenheim, has been appointed to succeed Dr. Rudolf Aderhold as director of the Imperial Biological Institute for Agriculture and Forestry, at Dahlen.

Maine Farmer for May 9 and 16 contains an interesting symposium by a large number of agricultural college and experiment station workers on the present demand and outlook for men with agricultural training and education.

EXPERIMENT STATION RECORD.

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau requests and remittances should be directed to the Chief of the Bureau. The price of the Record is \$1 per volume, or 10 cents per number. The prices of other technical publications are given in the list above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XVIII.

JULY, 1907.

No. 11.

The most vital question before the experiment stations to-day is that of human equipment. State and Federal appropriations have increased at a gratifying rate and spacious buildings have taken the place of cramped and inadequate makeshifts, but the men to carry forward this work have not been prepared in suitable numbers to meet the growing demand. The pressure is now becoming intense and it is recognized that our work of development must come practically to a standstill unless there can be an influx of men specially trained for its service. The man is the starting point in all investigation and the all-controlling factor. Without a presiding genius at the head generous funds and elaborate equipment become ineffectual.

In view of the fact that endowments have increased by million-dollar steps, it is not surprising that there should be much difficulty in securing a corresponding equipment of men with a genius for observation, who have ripened into usefulness. And now that there is a systematic movement in the direction of more thorough investigation of agricultural problems, it is evident how little attention our colleges have been giving to the training of agricultural investigators, and how low a standard they have themselves placed upon the requirements of experiment station work. The chief reason for the present shortage is found in the new standards which are being established for this work rather than in the fact that a relatively smaller number of men are presenting themselves for it. These standards impose additional requirements and qualifications, and thus practically eliminate from consideration many who might formerly have been drafted upon.

In the past it has been possible to carry on certain grades of work with men who had had little beyond the agricultural college course, coupled with a few years of experience. Such men have a far smaller place in the future, for their limitations are soon reached and they can not fill satisfactorily the higher positions or carry on advanced lines of investigation. The appointment of unqualified men, even to meet existing exigencies, is now acknowledged to be of doubtful expediency. Many have been the disappointments from an untried

and undeveloped man placed in the midst of ideal surroundings and opportunities to which he failed to rise.

Insufficient preparation on the part of workers is responsible for many of the defects of station activity. To it is due the low standards of investigation frequently met with, inconclusive and incomplete work, and many immature conclusions and deductions. It is also responsible, in large measure, for the estimation in which the agricultural work is held by scientific men in general. The need is not merely one for men, but for men of special qualifications and preparation; for men as broadly and thoroughly trained as in any department of research, men who know the methods and the meaning of research. The selection of a station staff "calls for the divining rod rather than the dragnet," but unfortunately the latter has been called into service too freely for the best interests of the work, and the present condition has well-nigh compelled its use.

The report of the committee on experiment station organization and policy at the Lansing meeting dealt largely with this subject. It pointed to the fact that the unprecedented demand for men trained in agricultural subjects is resulting in the appointment to important positions of young men practically fresh from graduation, and necessarily deficient in their training. The responsibilities of these positions and the salaries attached are out of all proportion to either the experience or the scholarship of the men appointed. This was deprecated as being seriously detrimental to the kind of work now expected of the stations. Such work, it was urged, calls for special preparation following the college course, quite as much as investigation in any field of science. The reason for such appointments of unprepared men is usually found in the scarcity of men, but in some cases, unfortunately, is due to a low standard or a policy of false economy.

The committee urged upon appointing bodies the importance of securing men with the widest possible education and training, and upon the institutions "that they supply the proper conceptions of scholarship, which, under present conditions, the young men can hardly be expected to acquire as undergraduates, and that they make it clear to young men that satisfactory permanent service can come only through the best preparation the world offers. . . . The agricultural colleges are primarily fitting their graduates not for investigators and teachers but for practical work in husbandry. Good as the courses are for this purpose they are only preparatory to the more advanced study needed by the investigator and the teacher. They do not, nor can they perhaps be expected to, in their undergraduate work, furnish the atmosphere best adapted to the scientific spirit and ideal."

When the exigencies of the situation are such that an institution

finds itself compelled to advance to responsible position and good salary a man of inadequate preparation, the committee specially recommended "that the arrangement shall include a definite understanding to the effect that he shall at once enter upon graduate work in the institution in which he is employed, wherever this is at all practicable, and that in any event there shall be definite plans for his temporary relief in the very near future for the purpose of encouraging graduate study in the best universities of the world." It argued that every possible advantage and encouragement should be held out to men who enter this work to adequately prepare themselves for it.

In view of the necessity to which some stations have been driven these suggestions are worthy of consideration. They place upon the stations themselves the responsibility for seeing to it that the men they select for their work shall ultimately receive training which shall suit them to their vocation, give them the proper point of view, and inculcate the true scientific spirit. Without doubt a great deal of good can be accomplished in that way, and it will help to determine whether or not a man is worthy of encouragement in the work.

There were two other papers presented at the Lansing meetings which bore upon this general subject, and which evidence not only the attention which it is attracting among thoughtful men, but indicate how live a question the personnel of the stations has become. One of these addresses was by Dr. H. P. Armsby, as president of the Society for Promotion of Agricultural Science, and was devoted to Research as a Career. This dealt more than incidentally with the human element in experiment station activity.

Doctor Armsby naturally recognized the man as the central factor in research, and he pointed out that in urging means for the support of investigation "we are inclined to assume not only the present existence of an adequate body of investigators, but that their number, like that of operatives in a factory, may be indefinitely increased as occasion arises. . . . The investigator in agriculture, if he be a real investigator, is a student of science. He is not a mere observer of nature or of practice." Addressing himself to the subject of providing an adequate supply of workers, he considered what should be the training for research in agriculture and the most effective means of acquiring it.

In the first place, "the investigator should have a broad and severe training in science, including actual work in research under the direction and inspiration of an experienced investigator. He should not merely acquire a knowledge of the facts of science, but should saturate himself with the scientific method of thought and work." And in the second place, "the agricultural investigator must have an acquaintance with the practical problems and conditions of agricul-

ture," for his projects " must bear definite relation to the actual problems of agriculture." This is a broad and efficient programme for preparation. Ideally it should come from the agricultural college, but these colleges have as yet given but little attention to that grade of instruction, and it was considered doubtful whether they are at the present time able to provide this training and atmosphere. Under present circumstances it was advised that the prospective investigator spend some time at a nonagricultural university, or failing this, seek a position under some competent investigator where he can take part in and imbibe the atmosphere of research.

Doctor Armsby also considered the question as to whether the conditions surrounding agricultural research are such as to attract men and lead them to prepare for it, and he outlined some of the conditions which contribute to this. Research positions can be made attractive to men by affording opportunity to do work from which credit and responsibility may result. While there must inevitably be much routine work, this should not be organized on the factory basis. A large degree of responsibility and freedom should be allowed to each group of workers, for in this way individual initiative is preserved and encouraged and more opportunities for advancement are open to young men. " In this way the university function of the research institution is most effectively performed and the training of the young worker in the method and spirit of scientific investigation most rapidly advanced." Like all branches of scientific activity, the conditions should be characterized by a notable degree of academic freedom, and there must likewise be freedom of discussion.

While large pecuniary rewards can not be expected from research in agriculture, there should be a living wage which will enable the worker to have books, travel, maintain scientific affiliations, and live in a way becoming his position. Pressure of pecuniary needs should not force capable and competent men into other lines of work, " a tendency which has not been entirely lacking in recent years." But the pecuniary reward was considered only secondary, while the other reward, the satisfaction of rendering real service in the advancement of mankind, is such that it " should appeal with tremendous force to the generous soul of youth."

The other paper was by Dr. W. H. Jordan upon the subject of The Authority of Science, and likewise dealt largely with the conditions essential to effective inquiry, and especially the man side. Doctor Jordan developed in a very logical way the fact that the authority at present vested in science rests on conscientious scientific inquiry, which in turn rests upon the individual, for " science is an individual product." Since what we accept as science is not infallible, but

is subject to reversals, the reliability of scientific deductions is estimated largely on their authorship. "What is presented to us for truth takes form in the human mind, and the quality of what we are asked to believe bears a close relation to the development and equipment of the producing intellect. Unripe minds will inevitably produce unripe science."

This is a very pregnant thought, which lies at the bottom of experiment station efficiency. The station can be no stronger than its men. Its strength and efficiency and reliability are measured and restricted by the combined ability of its staff. Stimulating conditions, helpful supervision, suitable facilities and equipment count for much, but they are all secondary. "Material equipment is subsidiary to the intellectual," and the development of inquiry must logically begin with the preparation of men properly fitted to conduct research that is worthy of the name.

Regarding the grade of attainments necessary to research in agriculture, Doctor Jordan made no concessions to other departments of pure or applied science, but argued that "all that is required for progress in any other field of inquiry whatever in the way of efficiency of organization, scientific acumen, and severity of method is required here." His specifications for the agricultural investigator were rigid: "The real investigator must have what we speak of as initiative, fundamentally a natural quality that has been trained and developed in an atmosphere of scientific inquiry. . . . The true scientific mind is the truth-loving, truth-seeking mind. . . . Investigators in certain fields of agricultural research should be something more than mere technicians in science; they should be ripened men who see relations broadly, men who know affairs as well as principles." And of the men needed to-day he said: "The present fundamental need is for more young men endowed with a love of learning, of scholarly habit, and with integrity of mind and heart, whose ambition is not for notoriety, but for the conquest of truth, and who, with more thought for service than for salary, are anxious to aid in laying broad and deep the foundations of human thought and activity."

Doctor Jordan characterized the present condition as "out of balance," and he urged that "we should bring the situation into balance by giving more attention to the development of men." He went further and made this a moral condition of request for increased funds, for he contended that agriculture has no right to ask for larger sums of public money to be used in the study of its problems until there are available more men who are adequately equipped for the work of inquiry. The responsibility for meeting this condition he laid squarely at the doors of the colleges. "The further development of agricultural work in the United States," he said, "lies pri-

marily with the colleges and universities in the preparation of men;” and since the influence of the teaching institutions is the primary factor in the progress of agricultural knowledge, he questioned whether it is not now the privilege and duty of at least some of these institutions to more fully nourish and develop the spirit of inquiry. “Should you not deliberately set about recognizing and encouraging scientific initiative among your students and organizing courses of instruction that will give a substantial preparation for the work of investigation?” A strong appeal was made to these institutions not to allow themselves to be wholly concerned with the commercial side of agriculture, but while advancing the intelligence and prosperity of the farm and the shop to promote the love of learning and uphold the standards of the scholar.

This voices a sentiment which is gaining increased prominence—that the agricultural colleges have a duty to science as well as to the practice of agriculture, and that they should be looked to to furnish the leaders in the various branches of agricultural work as well as in the industry. It should be one of their functions to stimulate young men to prepare adequately for experiment station service, and to inculcate the proper point of view as to the requirements of that service and the kind of preparation necessary. No young man would expect to enter the practice of medicine without special graduate work. Is less required of the man who is to seek out and interpret the laws of nature for his fellow-men?

Not all of the colleges are ready to offer graduate work, but many of them can discover among their students the exceptional man with the latent traits of the investigator, and stimulate and guide him in the direction of his development.

CONVENTION OF ASSOCIATION OF AMERICAN AGRICULTURAL COLLEGES AND EXPERIMENT STATIONS, 1907.

E. W. ALLEN, Ph. D.,
Office of Experiment Stations.

This association held its twenty-first annual convention at Lansing, Mich., May 28, 29, and 30, 1907. The convention was the most notable one in the history of the association in that it actively participated in the celebration of the fiftieth anniversary of the pioneer agricultural college of this country. The significance of this anniversary to the land-grant colleges as a whole, and some of the features of the occasion, were referred to editorially in the previous issue.

It was an important day for all of these institutions—not merely one for self-glorification, but for sober consideration of the place which they should hold and are filling in American education, the outlining of high conceptions and standards of the mission and the duties of these institutions in a broad way, and the means by which these ends may best be met. These considerations lent a special value to the proceedings of the convention, and taken with the account of the celebration as a whole, to be published separately, will form a most interesting chapter in the history of the land-grant colleges.

The meetings of the first two days of the convention were held in the Masonic Temple in Lansing, and were devoted to the usual business of the association and its sections. These meetings were well attended and suffered nothing from the exercises in progress out at the college. About 130 delegates and visitors were registered, including visitors from Canada, Cuba, Germany, and Scotland. The third day, May 30, the session was held in a large assembly tent on the college grounds and formed part of the anniversary celebration. The programme was in charge of the association, and the session was presided over by its president. Three papers were presented relating to the land-grant colleges, which are noted further on.

Although this formed the final session of the convention, the association was largely represented in the exercises of the following day, "Jubilee Day." The morning session on that day was held in the assembly tent, and consisted of addresses by Secretary Wilson, for the Department of Agriculture; President Angell, for Michigan and its university; President R. W. Stimson, for the East; Dr. H. C. White,

for the South; President Benjamin Ide Wheeler, for the West, and President James, for the Middle West. The afternoon session was held in the open air, the principal feature being an address by the President of the United States. This address was listened to with the greatest interest, as it voiced the President's appreciation of technical education, his belief in the high mission of the institutions of which the Michigan Agricultural College is a type, and in the necessity to the nation of developing not only the business of farming, but also the men and women engaged in that occupation and the conditions surrounding their life. The address was widely reported in the public press, and was so logical and forceful that it will have a strong influence in the development of public sentiment.

Following the address, degrees were conferred upon the graduating class, and the following honorary degrees: Doctor of science, upon Dean W. A. Henry, Prof. Charles F. Wheeler, President H. C. White, Director C. F. Curtiss, Dean Thomas F. Hunt, William W. Tracy, and Gifford Pinchot; doctor of laws, upon President Angell, Dean Davenport, President W. E. Stone, H. W. Collingwood (editor of the *Rural New Yorker*, Mortimer E. Cooley (dean of the engineering department of the University of Michigan), Dr. W. H. Jordan, President E. A. Bryan, Prof. R. C. Carpenter (of Cornell University), and Secretary James Wilson.

There were numerous social functions connected with the celebration which the members of the association participated in and which added materially to the enjoyment of the occasion. Among these was a concert the evening of the 29th, at which Mendelssohn's Oratorio Elijah was presented; an illumination, torchlight procession, the "oak chain" march by the young women of the college, and a reception on the evening of the 30th; luncheon in the women's building the 30th and 31st, and visits to the buildings and fields of the college and station under the direction of capable guides. On Saturday, June 1, the association and other representatives to the anniversary were entertained by Parke, Davis & Co., of Detroit, who ran a special train from Lansing to Detroit for the delegates, serving breakfast en route, and escorted them through their extensive and interesting works. In the afternoon a steamer trip was enjoyed on the river through the courtesy of the same firm, dinner being served on the boat.

GENERAL SESSIONS.

The general sessions of the convention were presided over by Dean L. H. Bailey, president of the association, and Director M. A. Scovell, vice-president. Dean Bailey delivered the presidential address on the evening of the first day upon the subject, The State and the Farmer, which he discussed from the standpoint of self-help and

governmental assistance. He laid much stress on the importance of personal and local initiative in solving difficulties and effecting reforms, and discussed the general question as to what it is wise and just for the State to do in aid of the farmer.

His remarks dealt with the leading questions relating to the improvement of agriculture as an industry, the men connected with it, the conditions of country living, and similar educational and economic aspects. This led to a consideration of the various agencies of the State and of the nation for agricultural advancement, the respective functions of these agencies and their relationships, with an attempt to outline a logical and efficient system extending from the National Government to the individual farmer. The address was suggestive rather than exhaustive, and outlined so sharply many of the problems for future solution that the association voted to have it printed at once for distribution in advance of the proceedings.

The report of the executive committee was presented by its chairman, Dr. H. C. White, who briefly reviewed the events of the year. Among these were the increase of funds to the land-grant colleges through the passage of the Nelson amendment to the current agricultural appropriation act, and the designation of the colleges as depositories of public documents. It was deemed best to attempt no action relative to the establishment of a national university at Washington, as no further effort had been made by the National Association of State Universities or others interested. Through its chairman the committee had endeavored, at a conference held November 21, 1906, to secure the admission of the land-grant colleges to the benefits of the Carnegie Foundation for the Advancement of Teaching. While the views of the board of trustees are at present adverse to the admission of these institutions, no final decision has been reached, and an invitation to another conference in advance of the next annual meeting of the board has been received. Action relative to the occasional meeting of the association with the National Educational Association, for the discussion of the pedagogies of agriculture and allied subjects, was deferred in view of the efforts being made to secure the establishment of a department of rural education in that association.

The association adopted a resolution expressing its profound appreciation of the services of Hon. Knute Nelson, of Minnesota, in securing the increased appropriation to the land-grant colleges. President White was also authorized to conduct further negotiations with the officers of the Carnegie Foundation.

The report of the treasurer, Director J. L. Hills, showed a balance from the previous year of \$958.38, receipts from dues of \$1,440, and disbursements of \$1,465.84, leaving a balance of \$932.54. Subscriptions to the fund for the graduate school were also received from

seven institutions, amounting to \$175. Of this amount, \$125 was turned over to the University of Illinois toward paying the expenses of the last session of the school.

The report of the bibliographer, Dr. A. C. True, took the form of brief historical notes on some early agricultural text-books, the status of instruction in the natural sciences fifty years ago, an account of a convention held in Chicago in 1871, which is said to have been of marked influence in the inauguration of experimental work, and a résumé of the work of Dr. Albrecht Thaer, of Hanover, Germany (1752-1828), one of the founders of the present system of agricultural education in Europe, and indirectly a factor in that of this country. In the discussion that followed, other data of similar nature were brought out, and much interest was shown in the general subject. It was urged that a complete history of the agricultural educational movement in this country should be brought together at an early date, and a committee, consisting of Doctor True, Dean Davenport, and Dean Henry, was appointed to take charge of this matter.

The report of the committee on instruction in agriculture, presented by Doctor True, as chairman, stated that a series of exercises for elementary instruction in agronomy had been prepared and published as a bulletin of this Office. A more advanced course in agronomy, supplementing this and designed for the use of secondary schools of relatively high grade, had been made ready for publication. The preparation of similar elementary and secondary courses in animal production and related topics is to be undertaken. The subcommittees on college courses in rural engineering and home economics reported progress.

The report of the committee on graduate study, submitted by President M. H. Buckham, stated that preliminary arrangements had been made to hold the next session of the summer school at Cornell University, with the cooperation of the New York State Experiment Station, in the summer of 1908, with Doctor True as dean. Special attention is to be centered on the interrelations of the chemical and biological groups of studies. The value of the school to both the educational and investigational work of the association was pointed out, together with the necessity for adequate financial support. It was voted to continue the present system of asking contributions from the several colleges, and the amount was fixed at \$25 for each institution, payable on or before July 1, 1907, and annually thereafter.

President K. L. Butterfield reported for the committee on extension work that a circular letter had been sent to the heads of the land-grant colleges, calling attention to the recommendations presented at the previous convention relative to the establishment of departments of extension teaching in agriculture. Replies received from

42 institutions representing 39 States were briefly summarized to show the status of the work in each case. Such departments are now formally established in 6 institutions, and in 3 others faculty committees have been appointed to study conditions and methods. Several institutions are hopeful of organizing the work in the near future, while at several extension work is proceeding along other lines. A lack of sufficient funds was in nearly every case reported as the chief obstacle to its development.

In connection with the extension work the need of a central agency to concentrate and correlate the efforts of the different institutions was emphasized by a number of speakers. A resolution was adopted favoring the granting of larger appropriations to the Office of Experiment Stations for the enlargement of its activities along the lines of "investigations and publications in relation to methods of instruction in agriculture relating to the farm, to the farm home, and to rural interests generally."

The report of the committee on station organization and policy was presented by its chairman, Dean Davenport. In view of some difficulty having been experienced by college and station workers in securing the publications of the stations, it was strongly urged that all the stations use the "official" mailing list prepared by this Office, either for mailing their bulletins or keeping their mailing lists revised, and that the institutions notify the Office promptly of all changes in their staffs. Inquiry developed the fact that only about two-thirds of the stations now use this list regularly.

A special feature of the report related to the kind of men suited to station work and their training. This is noted editorially in this number.

The committee expressed its appreciation of the work of this Office in furthering the interests of agricultural experimentation, and in view of the rapid growth of the stations and the increasing importance of these relations it was recommended that the association request its executive committee to confer with the Secretary of Agriculture with reference to its extension and reorganization as a bureau.

The report of the committee was adopted, together with its recommendations.

The commission on organization and policy in agricultural research, appointed in accordance with a resolution adopted at the last convention (E. S. R., 18, p. 797), made a brief preliminary report through its secretary, Dr. W. H. Jordan. Two subcommittees have been appointed, one to consider the scientific and technical aspects and the other the sociological and economical relations. The commission has held one meeting, and it is expected that another session will be held in November and a final report made to the association in the fall of 1908.

The interest of the association in the investigations upon human and animal nutrition was manifested in resolutions advocating the continuance of the investigations on human nutrition which have been carried on by this Office for several years past, and indorsing the establishment by the Pennsylvania State College of an institute of animal nutrition as an independent department of research. The executive committee was instructed to take such action in each case as would aid in securing permanence to these lines of work.

Prof. Robert Wallace, professor of agriculture and rural economy in the University of Edinburgh, at the invitation of the association gave an interesting talk on the live stock of Great Britain, prefacing this with remarks on agricultural education in the United Kingdom.

Remarks were made by Prof. S. B. Green and President G. E. Fellows in advocacy of securing national aid to the land-grant colleges for the establishment and maintenance of forestry courses through the receipts from forest reserves. The importance of more adequate State aid in such matters was emphasized by Dean Davenport.

Several speakers expressed their appreciation of the usefulness of *Experiment Station Record* to the station and college workers, and urged that provision be made, by appropriation or otherwise, for more detailed abstracts than are practicable under present conditions.

The third day's session of the convention was held at the Michigan Agricultural College, and was devoted to three addresses dealing with separate phases of the work of the land-grant colleges—agricultural education, engineering education, and research.

The first of these, *The Development of Agricultural Education*, was presented by Dr. Elmer E. Brown, Commissioner of Education. This included a brief summary of the evolution of the agricultural colleges and allied agencies, together with an interpretation of the agricultural education movement and its outlook. In his judgment the real and lasting strength of agricultural education is to be found not in isolation, but in close coordination with general education, and through this with the real life of the people. It should therefore aim to develop not only capable leaders—"scientific experts who shall be able to teach the people the principles underlying the arts of life," but also an intelligent constituency with "the skill to take the science of the scientist and transform it into the art of their lives."

"A system of agricultural training is therefore demanded complete in its sequence from the lowest to the highest. Our elementary schools and high schools in country communities are still to be primarily schools of general education, but with much more training in the arts of the farm and the sciences lying near to those arts; our State colleges of agriculture and mechanic arts are to prepare young men and young women to read intelligently the literature of scientific

agriculture, to form independent judgments in agricultural matters, and to bring their new knowledge into connection with the real work of the farm. These State colleges, moreover, are to provide well-trained teachers of agriculture and related subjects for the elementary and secondary schools; the colleges of agriculture, still further, are to be cooperative educational institutions and not merely special and local institutions; they are to cooperate with similar institutions in other States, in order that the work of one may be strengthened by the work of all, and cooperate with the universities of their several States for the innumerable advantages to both which may come from such united effort. The National Department of Agriculture is undoubtedly to continue its remarkably wide and influential work, its expert investigations, the issuance of manifold and vastly useful publications, and its furtherance of all manner of agricultural education and research in the several States. Finally, the Bureau of Education is to do as thoroughly as possible the part of this work assigned to it." Especially at the topmost reach, "there must be that which is not commonly recognized as education at all—the pure research of the pure scientist—for no education can continue to be really alive unless it draws directly from some source of new and abounding knowledge a fresh supply never yet handled and made common among mankind."

The Development of Engineering Education in the Land-Grant Colleges was traced by President W. E. Stone. He pointed out that engineering instruction developed in these institutions more rapidly than the agricultural phases, partly because it was more readily reduced to concrete pedagogical form. The extraordinary development in manufacturing, mining, and transportation, and the great wave of scientific discovery and invention also created an exceptional opportunity. To this the land-grant colleges readily responded, so that they have always been foremost in the essential development of engineering instruction and, in the aggregate, are to-day its principal exponents.

The evolution of engineering courses was stated to have been largely along original lines, its aim being the development of the power to do things effectively in the belief that this is the modern criterion of education. The policy of adapting the methods and scope of instruction to the distinct needs and conditions of our industries has evoked much criticism as to its educational value, but has resulted in the establishment of a new education with a new spirit which has won the confidence of the commercial world and become the chief bulwark against the prejudice toward the college graduate. Thousands of young men have been trained for careers of great responsibility, influence, and remuneration, to the great advantage of the material interests of the country. They have made important contributions

to technical and scientific knowledge, have led to a better appreciation of the value of the application of scientific study and methods to business and industrial operations, and have been productive of citizenship of a high quality.

At the same time, the work of these institutions thus far has been largely occupied with laying foundations. They have been burdened with the demand for practical men. A differentiation of the instructional work by which the more elementary phases will be administered in industrial, trade, and manual training schools is, however, forthcoming, leaving the engineering schools free to devote their resources to instruction and research in the higher branches of technology, with vastly beneficial results. The general establishment of experimental bureaus or laboratories analogous to the agricultural experiment stations was predicted as a logical step in this direction.

Dr. W. H. Jordan's address was upon The Authority of Science. This authority, he explained, is derived not from platform speculations, magazine exploitation of theories, nor reports of progress, but from severely tested and verified knowledge; and he proceeded to outline in a logical and forceful way the conditions which determine the reliability of scientific deductions, factors which have been inimical to agricultural research of the true type in this country, and the need of broader conceptions and greater freedom.

With a frankness that made his meaning unmistakable, but with a fairness and appreciation that recognized the full value of this great movement, the speaker pointed out that much of the so-called agricultural inquiry in this country has been not so much research as the exploitation of existing knowledge, obtained in many instances from foreign sources without amplification or adaptation. "Although important new truths have been brought to light, our efforts at inquiry have neither produced results nor commanded the respect of the scientific world to an extent commensurate with the generous means applied. During the past twenty-five years we have been busy, instead, with much agricultural speaking and writing." As a result, "we are now seeing with greater distinctness every year that the more complex and more important problems of agriculture are still unsolved, and that because of this our utterances to the practical man are still lame and halting." The investigator was pointed to as the primary consideration in scientific research, and he was considered from the standpoints of his personal equipment for investigation, his motives or point of view, and his environment.

Doctor Jordan made an earnest appeal to the colleges and universities to give more attention to the training and preparation of men for this work, and the inculcation of the proper spirit and point of view. "It is a serious question," he said, "whether we are right in our educational plans when we place almost the entire emphasis upon

the commercial or business side of agriculture and the industries, or whether in doing this we are promoting the highest utility of agricultural and industrial education." Without an increase in the supply of men he declared that increased funds can not be efficiently employed, and further agricultural development will inevitably be checked.

Portions of this notable address are referred to quite fully in the editorial pages of this issue.

The election of officers for the ensuing year resulted in the selection as president of J. L. Snyder, of Michigan, and as vice-presidents of E. A. Burnett, of Nebraska; H. H. Harrington, of Texas; E. A. Bryan, of Washington; C. D. Woods, of Maine, and H. C. Price, of Ohio. J. L. Hills, of Vermont, was reelected secretary and treasurer; A. C. True, of this Office, bibliographer; and H. C. White of Georgia, J. L. Snyder of Michigan, W. E. Stone of Indiana, W. H. Jordan of New York, and C. F. Curtiss of Iowa, as members of the executive committee.

In the section on college work and administration, R. W. Stimson, of Connecticut, was chosen chairman, and E. R. Nichols, of Kansas, secretary. C. E. Thorne, of Ohio, was chosen chairman, and P. H. Rolfs, of Florida, secretary of the section on experiment station work.

The vacancies in the committees occurring through the expiration of terms were filled by the following appointments: Committee on instruction in agriculture, H. T. French of Idaho and H. C. White of Georgia; committee on graduate study, M. H. Buckham of Vermont and R. H. Jesse of Missouri; committee on extension work, W. C. Latta of Indiana and C. F. Curtiss of Iowa; committee on station organization and policy, H. J. Wheeler of Rhode Island and E. B. Voorhees of New Jersey.

SECTION ON COLLEGE WORK AND ADMINISTRATION.
